Scope – ACI 562-19 complements the IEBC by providing specific direction on how to design concrete repairs and how to handle the unique construction problems associated with repair. This standard helps the designer assess the existing structure in accordance with the IEBC. The standard then provides the requirements that bridge the inconsistencies and gaps in acceptable criteria that occur from the two following situations that a designer must solve: one, repairing a structure according to the original building code used at the time it was built using today’s construction methods and materials; or, repairing a structure built according to an older building code but repaired according to the latest building code. Note that ACI 562 does not directly address the evaluation of lateral-force resisting systems in high seismic areas. ASCE 41 is the appropriate standard for this situation as stated in the IEBC and ACI 562.

Benefits – There are many benefits that ACI 562 provides for the designer, owner, contractor, materials providers, building code official and the public. A few of these benefits are:

- Provides a level of expectation of life safety to the public in buildings where repairs or rehabilitation is performed on concrete structural elements.
- Provides clearly defined, uniform requirements aimed at extending the service life of existing structures.
- Provides minimum requirements for safety and quality of concrete repair.
- Establishes clear responsibilities between owners, designers, and contractors.
- Provides building code officials with a means to evaluate rehabilitation designs.
- Provides specific repair requirements that often result in less costly repairs compared to repairs required to meet only new construction requirements.

Flexibility – ACI 562 permits flexibility in evaluation, design, construction and repair materials to provide economies while establishing expected performance for the service-life of the rehabilitation or repairs.

Resources – Also, there many resources that complement ACI 562. Among these are:

- ACI 563-18, Specifications for Repair of Structural Concrete in Buildings
- MNL-3(16) Guide to the Code for Assessment, Repair, and Rehabilitation of Existing Concrete Structures
These resources are readily available to provide greater understanding of assessment, repair and rehabilitation of concrete structural elements. ACI MNL-3 provides case studies demonstrating the ease of use of ACI 562. Numerous technical notes, reports, guides, and specifications that provide background information and technical support are available through other organizations, such as American Society of Civil Engineers, British Research Establishment, Concrete Society, International Concrete Repair Institute, National Association of Corrosion Engineers, Post-Tensioning Institute, Society for Protective Coatings, and US Army Corps of Engineers. Many of these organizations publications related to concrete repair can be found in the Concrete Repair Manual.

**Sustainability** - Reference of ACI 562 in the IEBC will help improve the confidence of owners, builders, and developers regarding effective repairs, upgrades, and reuse of existing buildings in lieu of demolition and replacement. Typically, extending the life of existing buildings is substantially more sustainable than demolition and new construction. Adoption of ACI 562 by reference is needed to help facilitate efforts that conserve energy and resources while maintaining a minimum level of requirements to ensure reasonable levels of life safety, and welfare are afforded to the public.

**State and Local Adoptions** – Jurisdictions see the need for these requirements. As the model for state and local adoptions, the IEBC should include this reference with appropriate charging language. ACI 562 is already being used in several jurisdictions:

**Hawaii:** Hawaii was the first state to adopt ACI 562 by reference. The following provisions are included in the State Building Code Council HAWAII STATE BUILDING CODE, which became effective on November 13, 2018:

“3401.6 Alternative compliance.

1) Work performed in accordance with the International Existing Building Code shall be deemed to comply with the provisions of this chapter.

2) Work performed in accordance with the 2016 version of the American Concrete Institute Committee 562, “Code Requirements for Assessment, Repair, and Rehabilitation of Existing Concrete Structures” shall be deemed to comply with this chapter when used as a supplement to the requirements of this chapter or the International Existing Building Code. Wherever the term International Existing Building Code (IEBC) is used in ACI 562-16, it shall mean International Existing Building Code or Chapter 34 of the International Building Code.”

**Ohio:** The Ohio Board of Building Standards Ohio adopted rule changes identified as Amendments Group 95. Included in this group is:

3401.6 Concrete evaluation and design procedures. Evaluation and design of structural concrete repairs and rehabilitation shall be in compliance with Chapter 34 and ACI 562.

ACI, a professional technical society, has developed this standard in response to industry needs and to help assure minimum levels of life safety results where repairs and rehabilitation are associated with concrete structural elements. For this reason and the other benefits identified in this reason statement, ACI recommends this code change proposal for committee approval as submitted.

**New York City:** The New York City Buildings Department issued BUILDINGS BULLETIN 2015-017 in December 2017 Conditions of Acceptance for Fiber Reinforced Cementitious Matrix strengthening systems.

FRCM shall comply with the NYC Construction Codes and the following applicable provisions:

A. **Design**

1. FRCM system shall be designed in accordance with the ACI 549.4R-13 Guide for the Design and Construction of Externally Bonded Fabric-Reinforced Cementitious Matrix (FRCM) Systems for Repair and Strengthening Concrete and Masonry Structures with properties used for design obtained from tests performed in accordance with AC 434. Fire-resistance-rating and interior finish requirements shall be in accordance with the NYC Construction Codes, manufacturer’s recommendations and the conditions of the required listing.

2. For repairs and upgrade achieved with unprotected external FRCM, the increase in flexural or shear strength provided by the external reinforcing system shall not exceed 50% of the existing structural capacity of the member prior to strengthening. This increase should be checked before applying the strength reduction factor.

3. Careful consideration should be given to determine reasonable strengthening limits. These limits are imposed to guard against collapse of the structure should bond or other failure of the FRCM system occur due to damage, vandalism, or other causes. The required strength of a structure without repair should be as specified in in accordance with ACI 562 Code Requirements for Assessment, Repair, and Rehabilitation of Existing Concrete Structures Section 5.5.

**Recommendation** – ACI, a professional technical society, has developed this ACI 562 in response to industry needs and to help assure minimum levels of life safety, health, and welfare for the public. For this reason and the other benefits identified in this reason statement, ACI recommends this code change proposal for committee approval as submitted.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The use of this referenced standard should in many cases reduce the cost of repair. Too often in the process of repair, there is insufficient information to determine acceptance criteria that is amicable to both the owner and the building code official. The result is the determination that the repair must meet the latest building code requirements for new construction. This standard increases the options available for repair and provides the acceptance criteria necessary to permit these options. A case study that illustrates this point: "ACI 562 has been referenced in expert reports for litigation cases, resulting in significantly reduced financial settlements. Denver-based J. R. Harris & Company recently used the code as a standard in several litigation reports assessing damages in existing concrete structures. As an approved consensus standard, according to American National Standards Institute (ANSI) procedures, ACI 562-13 has been accepted as the source standard to use for damage assessment and repair on individual projects by Greenwood Village and Pikes Peak Regional Building Departments in Colorado. Based on this acceptance, the consulting engineer was able to cite the code in their recommendation for structural remediation and determination of damages. In one case involving rehabilitation work on four buildings with faulty construction, J.R. Harris was able to reduce the repair costs from $12 million to $3 million, with a repair plan based on the lesser of the demand-capacity ratio based on either the original or current building code per ACI 562."

Staff Analysis: A review of the standard proposed for inclusion in the code, ACI 562-19, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2018.
2018 International Existing Building Code

CHAPTER 3 PROVISIONS FOR ALL COMPLIANCE METHODS

Revise as follows:

SECTION 301
ADMINISTRATION SCOPE

301.1 General. Applicability. The repair, alteration, change of occupancy, addition or relocation of all existing buildings shall comply with Section 301.2, 301.3, or 301.4. The provisions of Sections 302 through 305 shall apply to all alterations, repairs, additions, relocation of structures and changes of occupancy regardless of compliance method.

SECTION 302
GENERAL PROVISIONS

Delete without substitution:

302.1 Applicability. The provisions of Section 302 apply to all alterations, repairs, additions, relocations of structures and changes of occupancy regardless of compliance method.

SECTION 503
ALTERATIONS

Revise as follows:

503.1 General. Except as provided by Section 302.4, 302.5 or this section, alterations to any building or structure shall comply with the requirements of the International Building Code for new construction. Alterations shall be such that the existing building or structure is not less complying with the provisions of the International Building Code than the existing building or structure was prior to the alteration.

Exceptions:

1. An existing stairway shall not be required to comply with the requirements of Section 1011 of the International Building Code where the existing space and construction does not allow a reduction in pitch or slope.
2. Handrails otherwise required to comply with Section 1011.11 of the International Building Code shall not be required to comply with the requirements of Section 1014.6 of the International Building Code regarding full extension of the handrails where such extensions would be hazardous because of plan configuration.
3. Where provided in below-grade transportation stations, existing and new escalators shall have a clear width of less than 32 inches (815 mm).

Reason: An intent of the IEBC changes creating the 2018 edition was to make the provisions of Chapter 3 applicable to all existing building work regardless of the compliance method chosen. Our group's concern was that the route a code user must follow to get to requirements of Section 305 was unclear. Section 305 contains provisions which are 'exceptions' from compliance with the IBC and the ICC A117.1 standard; thus the text of 503.1 is incomplete because it doesn't like you to exceptions in Section 305. Section 305 is similar to 302.4 and 302.5 in that something less than full compliance with IBC is allowed. We noticed that the other compliance methods had no link within them to Chapter 3. The real problem, and the solution, is in the beginning of Chapter 3 where it fails to clearly state its purpose except in the title to the chapter. Titles are not code. It is essential that Section 301.1 state that Chapter 3 applies to all compliance methods as the title states.

We further noticed that 302.1 had such language covering Section 302 – but the rest of the chapter has no such statement. This proposal fixes it. Once stated in Section 301.1, it isn’t needed in 302. Once stated in 301, exceptions aren’t needed in 503 or in any of the other compliance methods. We also recommend the title of 301 be changed to either Scope or Applicability. Administration is something for Chapter 1 and not appropriate here.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The change provides an editorial correction to make sure the user understands that Section 305 also allows construction of alterations to a different and lesser technical requirement. And to make sure that the text of the Chapter is corrected to reflect the title – provisions for All Compliance Methods.
2018 International Existing Building Code

Add new text as follows:

303.4 Flood Loads Within flood hazard areas as established in Chapter 16 of the IBC, all existing buildings, structures and portions of buildings and structures, including substantial improvement and restoration of substantial damage to buildings and structures, shall be designed and constructed to resist the effects of flood hazards and flood loads. For buildings that are located in more than one flood hazard area, the provisions associated with the most restrictive flood hazard area shall apply.

[BS] 401.3 Flood hazard areas. In flood hazard areas, repairs that constitute substantial improvement shall require that the building comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

Reason: The IEBC does not include specific criteria for structures damaged by flood. New Section 303.4 will provide guidance and specific limitations on how flood loads must be addressed in existing buildings within flood hazard areas when undergoing substantial improvements and restoration of substantial damage.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change will clarify how the code is to be applied when existing structures are undergoing restoration or renovations due to flood damage when located in a flood zone. Currently the code is silent.
Proponent: Eirene Knott, representing Metropolitan Kansas City Chapter of the ICC (Eirene.Knott@brrarch.com)

2018 International Existing Building Code
Revise as follows:

SECTION 305
ACCESSIBILITY FOR EXISTING BUILDINGS

305.1 Scope. The provisions of Sections 305.1 through 305.9 apply to maintenance, change of occupancy, additions and alterations to existing buildings, including those identified as historic buildings.

305.2 Maintenance of facilities. A facility that is constructed or altered to be accessible shall be maintained accessible during occupancy.

305.3 Extent of application. An alteration of an existing facility shall not impose a requirement for greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

305.4 Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building.

305.4.1 Partial change of occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 305.6, 305.7 and 305.8.

305.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 305.4.1 and shall have all of the following accessible features:

1. Not fewer than one accessible building entrance.
2. Not fewer than one accessible route from an accessible building entrance to primary function areas.
4. Accessible parking, where parking is being provided.
5. Not fewer than one accessible passenger loading zone, where loading zones are provided.
6. Not fewer than one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, Items 1 through 6 shall conform to the requirements to the maximum extent technically feasible.

Exception: The accessible features listed in Items 1 through 6 are not required for an accessible route to Type B units.

305.5 Additions. Provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, a primary function shall comply with the requirements in Section 305.7–305.8.

305.6 Alterations. A facility that is altered shall comply with the applicable provisions in Chapter 11 of the International Building Code, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 305.7–305.8.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.
4. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building.
305.8.305.7 Scoping for alterations. The provisions of Sections 305.8.1 through 305.8.15 shall apply to alterations to existing buildings and facilities.

305.8.1 305.7.1 Entrances. Where an alteration includes alterations to an entrance that is not accessible, and the facility has an accessible entrance, the altered entrance is not required to be accessible unless required by Section 305.7. Signs complying with Section 1111 of the International Building Code shall be provided.

305.8.2 305.7.2 Elevators. Altered elements of existing elevators shall comply with ASME A17.1 and ICC A117.1. Such elements shall also be altered in elevators programmed to respond to the same hall call control as the altered elevator.

305.8.3 305.7.3 Platform lifts. Platform (wheelchair) lifts complying with ICC A117.1 and installed in accordance with ASME A18.1 shall be permitted as a component of an accessible route.

305.8.4 305.7.4 Stairways and escalators in existing buildings. Where an escalator or stairway is added where none existed previously and major structural modifications are necessary for installation, an accessible route shall be provided between the levels served by the escalator or stairways in accordance with Section 1104.4 of the International Building Code.

305.8.5 305.7.5 Ramps. Where slopes steeper than allowed by Section 1012.2 of the International Building Code are necessitated by space limitations, the slope of ramps in or providing access to existing facilities shall comply with Table 305.8.5.

**TABLE 305.8.5 305.7.5 RAMP SLOPE MAXIMUM RISE**

<table>
<thead>
<tr>
<th>SLOPE</th>
<th>MAXIMUM RISE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steeper than 1:10 but not steeper than 1:8</td>
<td>3 inches</td>
</tr>
<tr>
<td>Steeper than 1:12 but not steeper than 1:10</td>
<td>6 inches</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

305.8.6 305.7.6 Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered or added, the requirements of Section 1107 of the International Building Code for Accessible units apply only to the quantity of spaces being altered or added.

305.8.7 305.7.7 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered or added, the requirements of Section 1107 of the International Building Code for Type A units apply only to the quantity of the spaces being altered or added.

305.8.8 305.7.8 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being added. Where Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered and where the work area is greater than 50 percent of the aggregate area of the building, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being altered.

305.8.9 305.7.9 Jury boxes and witness stands. In alterations, accessible wheelchair spaces are not required to be located within the defined area of raised jury boxes or witness stands and shall be permitted to be located outside these spaces where the ramp or lift access restricts or projects into the required means of egress.

305.8.10 305.7.10 Toilet rooms. Where it is technically infeasible to alter existing toilet and bathing rooms to be accessible, an accessible family or assisted-use toilet or bathing room constructed in accordance with Section 1109.2.1 of the International Building Code is permitted. The family or assisted-use toilet or bathing room shall be located on the same floor and in the same area as the existing toilet or bathing rooms. At the inaccessible toilet and bathing rooms, directional signs indicating the location of the nearest family or assisted-use toilet room or bathing room shall be provided. These directional signs shall include the International Symbol of Accessibility and sign characters shall meet the visual character requirements in accordance with ICC A117.1.

305.8.11 305.7.11 Additional toilet and bathing facilities. In assembly and mercantile occupancies, where additional toilet fixtures are added, not fewer than one accessible family or assisted-use toilet room shall be provided where required by Section 1109.2.1 of the International Building Code. In recreational facilities, where additional bathing rooms are being added, not fewer than one family or assisted-use bathroom shall be provided where required by Section 1109.2.1 of the International Building Code.

305.8.12 305.7.12 Dressing, fitting and locker rooms. Where it is technically infeasible to provide accessible dressing, fitting or locker rooms at the same location as similar types of rooms, one accessible room on the same level shall be provided. Where separate-sex facilities are provided, accessible rooms for each sex shall be provided. Separate-sex facilities are not required where only unisex rooms are provided.

305.8.13 305.7.13 Fuel dispensers. Operable parts of replacement fuel dispensers shall be permitted to be 54 inches (1370 mm) maximum, measuring from the surface of the vehicular way where fuel dispensers are installed on existing curbs.
305.8.14 Thresholds. The maximum height of thresholds at doorways shall be \( \frac{3}{4} \) inch (19.1 mm). Such thresholds shall have beveled edges on each side.

305.8.15 Amusement rides. Where the structural or operational characteristics of an amusement ride are altered to the extent that the amusement ride’s performance differs from that specified by the manufacturer or the original design, the amusement ride shall comply with requirements for new construction in Section 1110.4.8 of the International Building Code.

Add new text as follows:

305.7.16 Dining Areas. An accessible route shall be provided throughout the dining area.

   Exception: An accessible route to raised or sunken areas or to outdoor seating areas is not required provided the same services and decor are provided in an accessible space.

Revise as follows:

305.7 Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to, or contains an area of primary function, the route to the primary function area shall be accessible. The accessible route to the primary function area shall include toilet facilities and drinking fountains serving the area of primary function.

   Exceptions:
   1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
   2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
   3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
   4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of a facility.
   5. This provision does not apply to altered areas limited to Type B dwelling and sleeping units.

305.9 Historic buildings. These provisions shall apply to facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet rooms would threaten or destroy the historic significance of the facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 305.9.1 through 305.9.4 for that element shall be permitted.

   Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

305.9.1 Site arrival points. Not fewer than one accessible route from a site arrival point to an accessible entrance shall be provided.

305.9.2 Multiple-level buildings and facilities. An accessible route from an accessible entrance to public spaces on the level of the accessible entrance shall be provided.

305.9.3 Entrances. Not fewer than one main entrance shall be accessible.

   Exception: If a public entrance cannot be made accessible, an accessible entrance that is unlocked while the building is occupied shall be provided; or, a locked accessible entrance with a notification system or remote monitoring shall be provided.

   Signs complying with Section 1111 of the International Building Code shall be provided at the public entrance and the accessible entrance.

305.9.4 Toilet and bathing facilities. Where toilet rooms are provided, not fewer than one accessible family or assisted-use toilet room complying with Section 1109.2.1 of the International Building Code shall be provided.

   Reason: The way the accessibility provisions currently read in the 2018, it’s not clear as to when the primary function requirements apply except as directed by Section 305.4.1 for a partial change of occupancy. By relocating the provisions to occur after the list of scoping items, the user can more easily follow the flow of what code language will apply to their project. As it is currently written, it is not clear as to when Section 305.8 (scoping for alterations) will apply. If the flow is changed to be as follows, it makes more sense to the end user:

   305.4 - Change of occupancy

   305.5 - Additions

   305.6 - Alterations

   305.7 - Scoping for alterations
305.8 - Alterations affecting a primary function

305.9 - Historic buildings

I also added language to address dining areas, which was in the 2015 IEBC. I re-wrote the language to that it is not writing the exception within the requirement but rather what the requirement is with the exception being provided.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This is just reformatting current language so there is no impact to the construction cost.
IEBC®: SECTION 305.6, 305.6.2 (New), 305.6.3 (New), 305.6.4 (New), 305.8.1, 305.8.2, 305.8.3, 305.8.4, 305.8.5, TABLE 305.8.5, 305.9.9.1, 305.9.2, 305.9.3, 305.9.4

Proponent: Gina Hilberry, Scoping Task Group of ICC/A117.1 Standard Development Committee, representing United Cerebral Palsy (gina@cohenhilberry.com); Rick Lupton, representing Self (sparkylupton@msn.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net); Gene Boecker, representing Code Consultants, Inc. (geneb@codeconsultants.com)

2018 International Existing Building Code

SECTION 305 ACCESSIBILITY FOR EXISTING BUILDINGS

Revise as follows:

305.6 Alterations. A facility that is altered shall comply with the applicable provisions in Chapter 11 of the International Building Code, ICC A117.1 and the provisions of Sections 305.6.1 through 305.6.19, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 305.7.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.
4. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building.

305.7 305.6.1 Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to, or contains an area of primary function, the route to the primary function area shall be accessible. The accessible route to the primary function area shall include toilet facilities and drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of a facility.
5. This provision does not apply to altered areas limited to Type B dwelling and sleeping units.

Add new text as follows:

305.6.2 Accessible route. The altered element or space is not required to be on an accessible route, unless required by Section 305.6.1.

305.6.3 Accessible means of egress. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing facilities.

305.6.4 Alteration of Type A units. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.

305.6.5 Type B units. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building.

Delete without substitution:

305.8 Scoping for alterations. The provisions of Sections 305.8.1 through 305.8.15 shall apply to alterations to existing buildings and facilities.

Revise as follows:

305.8.1 305.6.6 Entrances. Where an alteration includes alterations to an entrance that is not accessible, and the facility has an accessible
entrance, the altered entrance is not required to be accessible unless required by Section 305.7. Signs complying with Section 1111 of the International Building Code shall be provided.

305.6.2 305.6.7 Elevators. Altered elements of existing elevators shall comply with ASME A17.1 and ICC A117.1. Such elements shall also be altered in elevators programmed to respond to the same hall call control as the altered elevator.

305.6.8 Platform lifts. Platform (wheelchair) lifts complying with ICC A117.1 and installed in accordance with ASME A18.1 shall be permitted as a component of an accessible route.

305.6.9 Stairways and escalators in existing buildings. Where an escalator or stairway is added where none existed previously and major structural modifications are necessary for installation, an accessible route shall be provided between the levels served by the escalator or stairways in accordance with Section 1104.4 of the International Building Code.

305.6.10 Ramps. Where slopes steeper than allowed by Section 1012.2 of the International Building Code are necessitated by space limitations, the slope of ramps in or providing access to existing facilities shall comply with Table 305.6.5. 305.6.10.

<table>
<thead>
<tr>
<th>SLOPE</th>
<th>MAXIMUM RISE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steeper than 1:10 but not steeper than 1:8</td>
<td>3 inches</td>
</tr>
<tr>
<td>Steeper than 1:12 but not steeper than 1:10</td>
<td>6 inches</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

Add new text as follows:

305.6.11 Determination of number of units Where Chapter 11 of the International Building Code requires Accessible, Type A or Type B units, where units are being altered or added, the number of Accessible, Type A and Type B units shall be determined in accordance with Sections 305.6.11.1 through 305.6.11.3.

Revise as follows:

305.6.11.1 Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered or added, the requirements of Section 1107 of the International Building Code for Accessible units apply only to the quantity of spaces being altered or added.

305.6.11.2 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered or added, the requirements of Section 1107 of the International Building Code for Type A units apply only to the quantity of the spaces being altered or added.

305.6.11.3 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being added. Where Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered and where the work area is greater than 50 percent of the aggregate area of the building, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being altered.

305.6.12 Jury boxes and witness stands. In alterations, accessible wheelchair spaces are not required to be located within the defined area of raised jury boxes or witness stands and shall be permitted to be located outside these spaces where the ramp or lift access restricts or projects into the required means of egress.

305.6.13 Toilet rooms. Where it is technically infeasible to alter existing toilet and bathing rooms to be accessible, an accessible family or assisted-use toilet or bathing room constructed in accordance with Section 1109.2.1 of the International Building Code is permitted. The family or assisted-use toilet or bathing room shall be located on the same floor and in the same area as the existing toilet or bathing rooms. At the inaccessible toilet and bathing rooms, directional signs indicating the location of the nearest family or assisted-use toilet room or bathing room shall be provided. These directional signs shall include the International Symbol of Accessibility and sign characters shall meet the visual character requirements in accordance with ICC A117.1.

305.6.14 Additional toilet and bathing facilities. In assembly and mercantile occupancies, where additional toilet fixtures are added, not fewer than one accessible family or assisted-use toilet or bathing room shall be provided where required by Section 1109.2.1 of the International Building Code. In recreational facilities, where additional bathing rooms are being added, not fewer than one family or assisted-use bathing room shall be provided where required by Section 1109.2.1 of the International Building Code.

305.6.15 Dressing, fitting and locker rooms. Where it is technically infeasible to provide accessible dressing, fitting or locker rooms at the same location as similar types of rooms, one accessible room on the same level shall be provided. Where separate-sex facilities are provided,
accessible rooms for each sex shall be provided. Separate-sex facilities are not required where only unisex rooms are provided.

305.8.13 Fuel dispensers. Operable parts of replacement fuel dispensers shall be permitted to be 54 inches (1370 mm) maximum, measuring from the surface of the vehicular way where fuel dispensers are installed on existing curbs.

305.8.14 Thresholds. The maximum height of thresholds at doorways shall be \( \frac{3}{4} \) inch (19.1 mm). Such thresholds shall have beveled edges on each side.

305.8.15 Amusement rides. Where the structural or operational characteristics of an amusement ride are altered to the extent that the amusement ride’s performance differs from that specified by the manufacturer or the original design, the amusement ride shall comply with requirements for new construction in Section 1110.4.8 of the International Building Code.

305.8.16 Historic buildings. These provisions shall apply to facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet rooms would threaten or destroy the historic significance of the facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 305.9.1 through 305.9.4 for that element shall be permitted.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

305.8.17 Site arrival points. Not fewer than one accessible route from a site arrival point to an accessible entrance shall be provided.

305.8.18 Multiple-level buildings and facilities. An accessible route from an accessible entrance to public spaces on the level of the accessible entrance shall be provided.

305.8.19 Entrances. Not fewer than one main entrance shall be accessible.

Exception: If a public entrance cannot be made accessible, an accessible entrance that is unlocked while the building is occupied shall be provided; or, a locked accessible entrance with a notification system or remote monitoring shall be provided.

Signs complying with Section 1111 of the International Building Code shall be provided at the public entrance and the accessible entrance.

305.9.4 Toilet and bathing facilities. Where toilet rooms are provided, not fewer than one accessible family or assisted-use toilet room complying with Section 1109.2.1 of the International Building Code shall be provided.

Reason: Sections 305.6 through 305.9 all address alterations but there is no connection between the sections. This is a problem when trying to determine the purpose of 305.8. Section 305.8 is titled ‘Scoping for alterations’, however many of the 15 provisions which follow are technical exceptions. Some of them are additional technical requirements. Eleven of the 15 are only found in the IEBC and four of them duplicate exceptions contained in the ICC A117.1 standard. Three of the 15 are telling the user how to calculate a requirement where not all units need to be accessible.

The intent of this proposal is editorial. It is simply to provide connections between all of the Sections of 305 specifically addressing alterations.

Substantive changes to these sections are found in companion proposals. This proposal does the following.

- It renumbers Section 305.7 to 305.6.1 to indicate that it is a subset of the alterations section. There is a companion proposal to revise the language of 305.6.1 to be more consistent with the corresponding ADA requirement.
- It changes the 4 exceptions now found in Section 305.6 into the next four subsections – 305.6.2 through 305.6.5. Having titled subsections allow for quicker access for code users than sorting through numbered exceptions.
- It deletes the confusing lead in provisions of 305.8 and relocates its various provisions as the next subsections – 305.6.6 through 305.6.18. We have submitted a companion proposal which would delete four of these 9 because they are redundant with exceptions in the ICC A117.1 standard.
- It renumbers Section 305.9 and its subsections to be 305.6.19 because it contains a set of provisions and exceptions unique to historic buildings.
- Finally, it groups 3 provisions into a new subsection 305.6.11 All 3 of these sections provide a calculation methodology for determining the number of required dwelling and/or sleeping units

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The intent of this proposal is to be 100% editorial by reorganizing existing provisions into a more logical format.
2018 International Existing Building Code

Revise as follows:

305.1 Scope. The provisions of Sections 305.1 through 305.9 apply to maintenance repair, change of occupancy, additions and alterations to existing buildings, including those identified as historic buildings.

305.2 Maintenance-Repair of facilities. A facility that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Reason: Repair is defined in the I-codes as:
[A] REPAIR. The reconstruction, replacement or renewal of any part of an existing building for the purpose of its maintenance or to correct damage.

Repair includes maintenance. In addition, Chapter 4 of the IEBC is titled ‘Repair’. This would clarify how the accessibility requirements are addressed for Chapter 4. Maintenance does not require additional revisions for the path of travel.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The IEBC addresses repairs, not maintenance. This is a terminology change only.
EB22-19

IEBC®: 305.2, 305.6, 305.9

Proponent: Dawn Anderson, representing self (gonedawning@yahoo.com); Gene Boecker, representing Code Consultants, Inc. (geneb@codeconsultants.com); Dan Buuck, representing National Association of Home Builders (dbuuck@nahb.org); David Collins, representing the American Institute of Architects (dcollins@preview-group.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net)

2018 International Existing Building Code

Revise as follows:

305.2 Maintenance of facilities. A facility that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Required accessible means of egress shall be maintained at all times during construction, demolition, remodeling or alterations and additions to any building.

Exception: Existing means of egress need not be maintained where approved temporary means of egress and accessible means of egress systems and facilities are provided.

305.6 Alterations. A facility that is altered shall comply with the applicable provisions in Chapter 11 of the International Building Code, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 305.7.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided added in existing facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.
4. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building.

305.9 Historic buildings. These provisions shall apply to facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet rooms would threaten or destroy the historic significance of the facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 305.9.1 through 305.9.4 for that element shall be permitted.

Exceptions: Exception-

1. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in historic buildings.
2. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

Reason: Building that have been built since 1990 have had to have accessible means of egress. Therefore, it should be clear that those accessible means of egress need to be maintained the same way we are asking for the route into the space to remain accessible. The language is the same at that used in IEBC Section 1505.2.

The change to Section 305.6 would effectively not allow for someone to remove an accessible means of egress from an existing building. At the same time, it would not ask for the addition of an accessible means of egress in buildings that were so old that they did not have them. These buildings will continue to be addressed through the fire and safety evacuation requirements in IFC Chapter 4.

The change to Section 305.9 would allow the same exception for historic buildings as currently allowed for existing buildings.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is already required in new construction. This may be in place in many existing buildings.

Proposal # 4413
IEBC®: SECTION 305, 305.2, 305.2.1 (New), 305.3

Proponent: Gina Hilberry, Scoping Task Group of ICC/A117.1 Standard Development Committee, representing United Cerebral Palsy (gina@cohenhilberry.com); Rick Lupton, representing Self (sparkylupton@msn.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net); Gene Boecker, representing Code Consultants, Inc. (geneb@codeconsultants.com)

2018 International Existing Building Code

SECTION 305 ACCESSIBILITY FOR EXISTING BUILDINGS

305.2 Maintenance of facilities. A facility that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Add new text as follows:

305.2.1 Prohibited reduction in accessibility An alteration that decreases or has the effect of decreasing accessibility of a building, facility or element, thereof, below the requirements for new construction at the time of the alteration is prohibited. The number of accessible elements need not exceed that required for new construction at the time of alteration.

Revise as follows:

305.3 Extent of application. An alteration of an existing facility shall not impose a requirement for greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Reason: The existing second sentence of Section 305.3 is a distinct limitation from that imposed by the first sentence. It is an important limitation and therefore needs to be its own section. The first sentence of new section 305.2.1 is identical to that found in 305.3 of the 2018 code with one key exception. We propose adding 'or element thereof' to the text to make it clear that it's not just overall accessibility, but also accessibility of individual elements such as a water closet compartment, an elevator, a dwelling unit, or a building entrance which cannot be reduced.

The second sentence of the new Section 305.2.1 is new. Its purpose is to address the situation where the number of required accessible elements was reduced between editions of the code. For example, the number of required accessible hotel sleeping room has been reduced between the early and current editions of the IBC. The exception would allow the number of accessible hotel rooms built under the 2003 IBC, to be reduced during an alteration to the number required under the 2018 IBC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Separating out the text into Section 305.2.1 and adding the elements reference is, on the whole, an editorial clarification of the existing text. The new second sentence might reduce costs of an alteration because fewer accessible elements may be needed. Such costs would be minor and hard to quantify.

Proposal # 4982
**EB24-19**

IEBC®: 305.4, 305.4.1

**Proponent:** Gina Hilberry, Scoping Task Group of ICC/A117.1 Standard Development Committee, representing United Cerebral Palsy (gina@cohenhilberry.com); Rick Lupton, representing Self (sparkylupton@msn.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net); Gene Boecker, representing Code Consultants, Inc.(geneb@codeconsultants.com)

**2018 International Existing Building Code**

Revise as follows:

**305.4 Change of occupancy.** *Existing buildings* that undergo a change of group or occupancy shall comply with this section. Sections 305.4.1 or 305.4.2, as applicable.

**Exception:** Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in *existing buildings* and facilities undergoing a *change of occupancy* in conjunction with *alterations* where the *work area* is 50 percent or less of the aggregate area of the building.

**305.4.1 Partial change of occupancy.** Where a portion of the building is changed to a new occupancy classification, any *alterations* shall comply with Sections 305.3, 305.6, 305.7 and 305.8.

**Reason:** The proposal is intended as editorial revisions making the code application clearer to all users.
*First - In 305.4 changing 'this section' to specific references to the 2 subsections clarifies what is being required.*

Second – In Section 305.4.1, we have added Section 305.3 to those for which compliance is required. Section 305.3 addresses limits to alterations which must be considered for all alterations. We have a companion proposal which splits the requirements of Section 305.3 into two sections; it would be our intent that this proposed reference addition in 305.4.1 also reference both sections.

The reference within Section 305.4.2 takes the user back to Section 305.4.1, therefore the added reference is also picked up for complete changes of occupancy.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
The changes are editorial. They help users get to the correct sections and to not miss key requirements.

Proposal # 5087
2018 International Existing Building Code

Revise as follows:

305.4 Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section. Sections 305.6, 305.7 and 305.8.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building.

Delete without substitution:

305.4.1 Partial change of occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 305.6, 305.7 and 305.8.

305.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 305.4.1 and shall have all of the following accessible features:

1. Not fewer than one accessible building entrance.
2. Not fewer than one accessible route from an accessible building entrance to primary function areas.
4. Accessible parking, where parking is being provided.
5. Not fewer than one accessible passenger loading zone, where loading zones are provided.
6. Not fewer than one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, Items 1 through 6 shall conform to the requirements to the maximum extent technically feasible.

Exception: The accessible features listed in Items 1 through 6 are not required for an accessible route to Type B units.

Reason: There are several arguments to simplify this section.

What this does administratively is take a change of occupancy and make it consistent with requirements for an alteration. This allows flexibility for small properties.

- The federal requirements in the 2010 ADA Standard do not address a change of occupancy – they treat all alterations the same. There is no justification for ICC to require a business in stand alone building to provide additional requirements past what is expected for a business in a multi-tenant building.
- The list in Section 305.4.2 basically lists all the elements in accessible routes, which is addressed in Section 305.7, but does not include bathrooms and drinking fountains. Therefore, it is unclear as to if renovations to those items are required in a complete change of occupancy, where they would be on the list for an alteration and a partial change of occupancy. This list does not add any clarification of improvements to the code.
- This could also be read that a complete change of occupancy would never have to fix the toilet rooms or drinking fountains since it is not in the list. If the alterations are small, allowing someone to spend money to fix the toilet rooms is addressed the needs of many individuals with mobility issue.
- If the part of the route missing is an elevator or extensive front ramp, the cost could make the existing building remain vacant since this section could be viewed as not tied to the 20% maximum cost allowance.
- The arguments against revising this section in past code cycles have all been around the issue of a change of occupancy with no alterations. Many building departments are not involved in changes of occupancy that do not include alterations. Even in jurisdictions that look at this, they do not require alterations for occupancies with lesser hazards. How much should you ask someone to spend if there are no construction costs? If it is a higher hazard, there will mostly likely be alterations – so just use those requirements.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.
**Cost Impact:** The code change proposal will decrease the cost of construction

Requiring the six route requirements in Section 305.4.2 for small buildings that undergo a change of occupancy can be a large cost. It is more appropriate to limit the cost of the route to 20% of the alteration - which this change will allow. In large buildings, this change will have minimal impact since they are more likely to already have the accessible route - or the cost will be a much smaller portion of their budget.
EB26-19
IEBC®: 305.4, 305.6, 305.8.8

Proponent: Dawn Anderson, representing self (gonedawning@yahoo.com); Gene Boecker, representing Code Consultants, Inc. (geneb@codeconsultants.com); Dan Buuck, representing National Association of Home Builders (dbuuck@nahb.org); David Collins, representing the American Institute of Architects (dcollins@preview-group.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net)

2018 International Existing Building Code

Revise as follows:

305.4 Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building area.

305.6 Alterations. A facility that is altered shall comply with the applicable provisions in Chapter 11 of the International Building Code, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 305.7.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.
4. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building area.

305.8.8 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being added. Where Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered and where the work area is greater than 50 percent of the aggregate building area of the building, the requirements of Section 1107 of the International Building Code for Type B units apply only to the quantity of the spaces being altered.

Reason: When the provisions were combined last cycle, the language specific to the work area method was lost. This is a clarification by using the exact verbiage that describes a Level 3 alteration in Section 604.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change is editorial.
2018 International Existing Building Code

Revise as follows:

305.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 305.4.1 and shall have all of the following accessible features:

1. Not fewer than one accessible building entrance.
2. Not fewer than one accessible route from an accessible building entrance to primary function areas.
4. Accessible parking, where parking is being provided.
5. Not fewer than one accessible passenger loading zone, where loading zones are provided.
6. Not fewer than one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, Items 1 through 6 shall conform to the requirements to the maximum extent technically feasible.

Exception: The accessible features listed in Items 1 through 6 are not required for an accessible route to Type B units.

Reason: There is no compelling reason to exempt buildings undergoing a complete change of occupancy to a Group R-2 apartment building for providing these 6 listed provisions. It must be first noted that Section 305.4 already exempts buildings where the work area is less than 50%.

305.4 Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building.

Where the action is a complete change of occupancy – such as an old warehouse to new condominiums, why should there not be an accessible entrance; accessible routes to the new units, signage where appropriate; parking and loading zones where provided and routes to such parking and loading? In all likelihood, these features will be added or altered. Please note that this only applies where there is a change of occupancy for the entire space. This does not impose improvements to the path of travel under Section 305.7 for remodeling areas of primary function. There remains an exception for R-2 uses in Section 305.7.

Cost Impact: The code change proposal will increase the cost of construction

The deletion of the exception may cause an increase in cost of some changes of occupancy to a Group R-2 building. We think it would be unlikely that a complete change of occupancy to residential where Type B (and likely Type A) units would be provided would not provide an accessible route to those units, nor have an accessible entrance to the building. The cost increase may result in reconfiguring existing parking to provide accessible spaces and providing a route to parking and loading locations.
Proponent: Gina Hilberry, Scoping Task Group of ICC/A117.1 Standard Development Committee, representing United Cerebral Palsy (gina@cohenhilberry.com); Rick Lupton, representing Self (sparkylupton@msn.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net); Gene Boecker, representing Code Consultants, Inc.(geneb@codeconsultants.com)

2018 International Existing Building Code

Revise as follows:

305.6 Alterations. A facility that is altered shall comply with the applicable provisions in Chapter 11 of the International Building Code, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 305.7.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to provide the provision for a Type B dwelling unit.
4. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing alterations where the work area is 50 percent or less of the aggregate area of the building.

Reason: The proposal eliminates exception 1 to the provision of alteration of accessible features in the IEBC. The exception isn’t needed for a few reasons:

1. It serves as a pointer to Section 305.7. Since compliance with 305.7 is applicable to any alteration affecting the area of primary function, the accessible route will be addressed through compliance with Section 305.7. No pointer is needed.

2. It may have been intended to say that an altered element still has to meet accessibility standards even if an accessible route isn't provided. Such is covered in Chapter 11 of the IBC and the ICC A117.1 standard.

3. It is confusing as an exception. Exceptions should point to something less stringent, but by pointing to Section 305.7, it address something that is more stringent.

As the code user can get to the issues addressed by the exception without the exception, it should just go away.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The deletion of the exception doesn’t change compliance requirements found elsewhere in the IEBC and the IBC, the code just will lose an unclear pointer.
305.7 Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to, or contains an area of primary function, the route an accessible path of travel to the primary function area shall be accessible provided. The accessible route path of travel to the primary function area shall include the accessible route, toilet facilities and drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route path of travel are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. The requirement to provide an accessible path of travel does not apply to alterations where alterations within the primary function area are limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to signs, mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of a facility.
5. This provision does not apply to altered areas limited to Type B dwelling and sleeping units.

Reason: The IEBC code is unclear with respect to this requirement which derives from the ADA. The term used in the ADA is ‘path of travel’. In the ADA it includes the accessible route to the primary function area as well as the telephones, toilet facilities and drinking fountains which serve the area of primary function. Saying ‘accessible route’ as it does in exception 1 is misleading. Path of travel could be defined in Chapter 2, but the last sentence of 305.7 is essentially the definition. As the term is not used elsewhere in the code, a chapter 2 definition seems unnecessary. Telephones are not included in the IEBC text because they are not typically part of the building regulated by the local building official. Telephone requirements for new construction are in Appendix E of the IBC.

Exception 3 is merged into exception 2 as they are both simply lists of elements exempt from the path of travel requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is primarily an editorial clarification of an existing requirement.
2018 International Existing Building Code

Revise as follows:

305.8.4 Stairways and escalators in existing buildings. Where an escalator or stairway is added where none existed previously and major structural modifications are necessary for installation, an accessible route shall be provided between the levels served by the escalator or stairways in accordance with Section 1104.4 of the International Building Code is required between levels served by such escalator or stairway.

Reason: We believe the intent of this section is to require an accessible route between stories where none now exists; but to not require additional accessible routes where one is already provided. The language is convoluted and unclear. We believe that the language can be simplified to send the users to Section 1104.4 of the IBC. Section 1104.4 provides all the direction and exceptions needed to clarify application of this section.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The intent is to provide clarity to this section through an editorial revision
EB31-19

IEBC®: SECTION 305, 305.8.5, TABLE 305.8.5, 305.8.9, 305.8.13, 305.8.14

Proponent: Gina Hilberry, Scoping Task Group of ICC/A117.1 Standard Development Committee, representing United Cerebral Palsy (gina@cohenhilberry.com); Rick Lupton, representing Self (sparkylupton@msn.com); Marsha Mazz, representing United Spinal Association (m.mazz@verizon.net); Gene Boecker, representing Code Consultants, Inc.(geneb@codeconsultants.com)

2018 International Existing Building Code

SECTION 305 ACCESSIBILITY FOR EXISTING BUILDINGS

Delete without substitution:

305.8.5 Ramps. Where slopes steeper than allowed by Section 1012.2 of the International Building Code are necessitated by space limitations, the slope of ramps in or providing access to existing facilities shall comply with Table 305.8.5.

<table>
<thead>
<tr>
<th>SLOPE</th>
<th>MAXIMUM RISE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steeper than 1:10 but not steeper than 1:8</td>
<td>3 inches</td>
</tr>
<tr>
<td>Steeper than 1:12 but not steeper than 1:10</td>
<td>6 inches</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

305.8.9 Jury boxes and witness stands. In alterations, accessible wheelchair spaces are not required to be located within the defined area of raised jury boxes or witness stands and shall be permitted to be located outside these spaces where the ramp or lift access restricts or projects into the required means of egress.

305.8.13 Fuel dispensers. Operable parts of replacement fuel dispensers shall be permitted to be 54 inches (1370 mm) maximum, measuring from the surface of the vehicular way where fuel dispensers are installed on existing curbs.

305.8.14 Thresholds. The maximum height of thresholds at doorways shall be 1/2 inch (19.1 mm). Such thresholds shall have beveled edges on each side.

Reason: Sections 305.8.5, 305.8.9, 305.8.13 and 305.8.14 are redundant with the A117.1 standard. For some of these, the standard provisions are a more comprehensive statement of the technical exemption for existing buildings and alterations. In addition these are “technical” exceptions, and not as the Title of 305.8 alludes to them being changes to the “scoping” of where accessible features are required. Therefore we propose deleting these four sections. The text of the equivalent provisions in the standard can be located as follows:

IEBC Sec. A117.1 Sec.

305.8.5 405.2, Exception; Table 405.2

305.8.9 807.3, Exception

305.8.13 308.3, Exception 2

305.8.14 404.2.4, Exception

Cost Impact: The code change proposal will not increase or decrease the cost of construction

These are editorial revisions. No requirements are being added or exceptions deleted. The provisions deleted here are still found in the ICC A117.1 standard.
2018 International Existing Building Code

Revise as follows:

305.8.10 Toilet rooms. Where it is technologically infeasible to alter existing toilet and bathing rooms to be accessible, one accessible single user toilet room or one accessible family or assisted-use toilet or bathing room constructed in accordance with Section 1109.2.1 of the International Building Code is permitted. The family or assisted-use toilet or bathing room shall be located on the same floor and in the same area as the existing toilet or bathing rooms. At the inaccessible toilet and bathing rooms, directional signs indicating the location of the nearest family or assisted-use toilet or bathing room shall be provided. These directional signs shall include the International Symbol of Accessibility and sign characters shall meet the visual character requirements in accordance with ICC A117.1.

305.8.11 Bathing rooms. Where it is technologically infeasible to alter existing bathing rooms to be accessible, one accessible single user bathing room or one accessible family or assisted-use bathing room constructed in accordance with Section 1109.2.1 of the International Building Code is permitted. This accessible bathing room shall be located on the same floor and in the same area as the existing bathing rooms. At the inaccessible bathing rooms, directional signs indicating the location of the nearest such bathing room shall be provided. These directional signs shall include the International Symbol of Accessibility and sign characters shall meet the visual character requirements in accordance with ICC A117.1.

Add new text as follows:

305.9.4 Toilet and bathing facilities. Where toilet rooms are provided, not fewer than one accessible single user toilet room or one accessible family or assisted-use toilet room complying with Section 1109.2.1 of the International Building Code shall be provided.

Add new text as follows:

305.9.5 Bathing facilities. Where bathing rooms are provided, not fewer than one accessible single user bathing room or one accessible family or assisted-use bathing room complying with Section 1109.2.1 of the International Building Code shall be provided.

Reason: The intent of this proposal is to clarify the code and coordinate with the terminology in the IPC. The proposal splits the requirements for toilet rooms and bathing rooms into separate sections for clarity. Historically, this requirement originally said ‘unisex’ toilet rooms were permitted but was revised many cycles ago to use the term ‘family or assisted use’ for consistency. The IPC now requires all single-occupant toilet rooms to be gender neutral. It is arguable if a family or assisted use toilet room is for a single user or not. Family or assisted use toilet rooms can include a urinal and a toilet, or both adult and child fixtures. Most of the time, an accessible family or assisted use and and accessible single user toilet rooms are technically exactly the same. The current language has caused questions about if this option in the code is only allowed where family assisted use toilet rooms are required in the IBC (Groups A and M), and/or allowed to meet the fixture counts. The IPC has also been revised to allow both single-user and family or assisted toilet rooms to count towards the required fixture count.

For historic buildings (Section 305.9.4), the same issue exists. In addition, while the title included ‘bathing rooms’ the text did not. Providing separate sections will allow for consistency for existing building and historic buildings that include shower facilities for occupants.

Below is the language in the 2018 IPC

403.1.2 Single-user toilet facility and bathing room fixtures. The plumbing fixtures located in single-user toilet facilities and bathing rooms, including family or assisted use toilet and bathing rooms that are required by Section 1109.2.1 of the International Building Code, shall contribute toward the total number of required plumbing fixtures for a building or tenant space. Single-user toilet facilities and bathing rooms, and family or assisted-use toilet rooms and bathing rooms shall be identified for use by either sex.

403.2.1 Family or assisted-use toilet facilities serving as separate facilities. Where a building or tenant space requires a separate toilet facility for each sex and each toilet facility is required to have only one water closet, two family or assisted-use toilet facilities shall be permitted to serve as the required separate facilities. Family or assisted use toilet facilities shall not be required to be identified for exclusive use by either sex as required by Section 403.4.

403.4 Signage. Required public facilities shall be provided with signs that designate the sex, as required by Section 403.2. Signs shall be readily visible and located near the entrance to each toilet facility. Signs for accessible toilet facilities shall comply with Section 1111 of the International Building Code.

403.4.1 Directional signage. Directional signage indicating the route to the required public toilet facilities shall be posted in a lobby, corridor, aisle or
similar space, such that the sign can be readily seen from the main entrance to the building or tenant space.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is mostly an editorial clarification and coordination with IPC terms.
Proponent: Kevin Brinkman, representing National Elevator Industry, Inc. (klbrinkman@neii.org)

2018 International Existing Building Code

Delete without substitution:

305.8.2 Elevators. Altered elements of existing elevators shall comply with ASME A17.1 and ICC A117.1. Such elements shall also be altered in elevators programmed to respond to the same hall call control as the altered elevator.

Reason: This requirement is not necessary and may conflict with the ASME A17.1/CSA B44 Safety Code for Elevators and Escalators. A17.1/B44 already has detailed requirements for alterations. All elevators in a group may not be the same. Some cars may serve additional landings, have different size cars, or other features. It may not be feasible to comply with A117 due to variations or in older equipment. This requirement is overly restrictive and adds unnecessary cost to building owners. It may deter building owners from making improvements to one elevator due to the additional cost of having to update all other elevators in the group and therefore, reduce accessibility.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This code change proposal will not increase or decrease the cost of construction because elevator alterations are already addressed in ASME A17.1/CSA B44.
2018 International Existing Building Code

Add new text as follows:

305.8.2 Accessible route. Exterior accessible routes, including curb ramps, shall be not less than 36 inches (914 mm) minimum in width.

Revise as follows:

305.9.1 Site arrival points. Not fewer than one exterior accessible route, including curb ramps, from a site arrival point to an accessible entrance shall be provided and shall not be less than 36 inches (914 mm) minimum in width.

Reason: The ICC A117.1 has increased the size of the exterior route from 36" to 48". This change was based on the recommendations from the Public Rights of Way, not the study that revised the other requirements in the standard. Therefore, this provision does not have allowances for existing buildings in the standard. Allowances for existing building for this item was not discussed. This should not result in any significant loss of accessibility.

Changing the width of sidewalks and curb cuts on a site may require extensive reconfiguration of the parking and sidewalks. The required width for means of egress and/or designer input into the needed width of sidewalks should be sufficient for existing sidewalks and curb cuts on private property.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This allows for existing exterior accessible routes to remain at 36" in width.
EB35-19

IEBC®: 305.8.6 (New)

**Proponent:** Ronald Clements Jr, representing VBCOA (clementsro@chesterfield.gov)

**2018 International Existing Building Code**

Add new text as follows:

**305.8.6 Dining areas.** An accessible route is not required to raised or sunken dining areas or outdoor dining areas where accessible dining areas with the same services are provided on the same floor level.

**Reason:** This provision for dining areas was in the work area method going back to the first edition. It was not in the prescriptive method when that method was introduced in the 2006 edition. When the accessibility provisions were consolidated in chapter 3 the dining area provision was lost; it was section 705.1.5 in the 2015 edition. It appears the loss was not intentional.

**Cost Impact:** The code change proposal will decrease the cost of construction.

This provides another option that could decrease construction cost.
2018 International Existing Building Code

Revise as follows:

305.9 Historic buildings. These provisions shall apply to facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet rooms would threaten or destroy the historic significance of the facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 305.9.1 through 305.9.4 for that element shall be permitted.

Exception: Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Sections 305.9.1 or 305.9.2.
2. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall be permitted to meet the provision for a Type B dwelling unit.
3. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

Reason: This proposal is for consistency between the exceptions allowed for existing buildings and historic buildings. These exceptions are in Section 305.6 for existing buildings. This clarifies that an existing historical building can use the same exceptions as existing buildings.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is a clarification.
EB37-19

305.9, 305.9.3, 305.9.5 (New)

Proponent: Dan Buuck, representing National Association of Home Builders (dbuuck@nahb.org); Marsha Maz, representing United Spinal Association (m.mazz@verizon.net); David Collins, representing The American Institute of Architects (dcollins@preview-group.com); Gene Boecker, representing Code Consultants, Inc. (geneb@codeconsultants.com); Dawn Anderson, representing Mayor’s Office on Disability (gonedawning@yahoo.com)

2018 International Existing Building Code

Revise as follows:

305.9 Historic buildings, structures. These provisions shall apply to facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet rooms would threaten or destroy the historic significance of the facility, historic structure, as determined by the authority having jurisdiction, the alternative requirements of Sections 305.9.1 through 305.9.4 for that element shall be permitted.

   Exception: Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

305.9.1 Site arrival points. Not fewer than one accessible route from a site arrival point to an accessible entrance shall be provided.

305.9.2 Multiple-level buildings and facilities. An accessible route from an accessible entrance to public spaces on the level of the accessible entrance shall be provided.

305.9.3 Entrances. Not fewer than one main entrance shall be accessible.

   Exception: If a public entrance cannot be made accessible in accordance with Section 305.8.1, an accessible entrance that is unlocked while the building is occupied shall be provided; or, a locked accessible entrance with a notification system or remote monitoring shall be provided.

   Signs complying with Section 1111 of the International Building Code shall be provided at the public entrance and the accessible entrance.

305.9.4 Toilet and bathing facilities. Where toilet rooms are provided, not fewer than one accessible family or assisted-use toilet room complying with Section 1109.2.1 of the International Building Code shall be provided.

Add new text as follows:

305.9.5 Type B units. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in historic buildings.

Reason: The provisions for existing buildings should always apply for historic buildings where technically feasible. This is in the rest of the Section 305, so the first sentence is not needed. The requirements for the entrances in 305.9.3 is making a statement instead of an exception for consistent with the format. The exception for Type B units was moved from being an exception to being a statement in the text.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is editorial.
2018 International Existing Building Code

Add new text as follows:

SECTION 306
MEANS OF EGRESS FOR EXISTING BUILDINGS

306.1 Occupant Load based on Capacity Where approved by the code official, the occupant load of any room, areas, space or story shall be permitted to be established as the number of occupant for which the existing means of egress capacity is adequate. Measures shall be established to prevent occupancy greater than the number and capacity of the means of egress components. Such measures can include, but are not limited to the posting of the occupant load for the room, area, space or story.

Reason: Many shell and core buildings are constructed with the minimum means of egress capacity for the anticipated use. However, when the space is finished, the new use may have spaces with occupant loads higher than originally anticipated. Therefore, the existing egress capacity is not adequate enough for the new space. This proposal provides an option to base the occupant load on the existing capacity of the space. It requires the building official's approval to use this option to reduce possible abuse of the requirement.

For example, if a space has two 36-inch wide doors that provide 34-inches of egress capacity, the maximum occupant load permitted in that space would be 340. In some cases, it is either very expensive or impossible to add an additional means of egress or capacity. If the calculated occupant load was greater than the 340, the building official could approve the reduction of the occupant load to a maximum of 340. They would then determine how that occupant load would be maintained which could include the posting of the occupant load in the space. This happens in office tenant improvements quite often. The original building was designed with an occupant load calculation for business use, but the new tenant space has some assembly functions that increase the occupant load.

This proposal was submitted to the Means of Egress Committee in the Group A Cycle. They felt that the requirement would be better located in the IEBC. Their other concerns were addressed by some revisions to the original language submitted to them.

Cost Impact: The code change proposal will decrease the cost of construction
By allowing the occupant load to be based on the egress capacity, the cost of additional exits or capacity will be eliminated.
SECTION 306
HEALTHCARE

306.1 General. Healthcare facilities including Group I-2, ambulatory care facilities and outpatient clinics undergoing repair, alterations, additions and change of occupancy shall be in accordance with Sections 306.1.1 and 306.1.2, as applicable.

306.1.1 Existing construction requirements. Existing Group I-2 facilities shall meet the minimum construction requirements in Chapter 11 of the International Fire Code.

306.1.2 Projections in Nursing Home Corridors. In Group I-2, Condition 1 occupancies, where the corridor is at least 96 inches wide, projections into the corridor width are permitted in accordance with Section 407.4.3 of the International Building Code.

Reason: This proposal creates a section in chapter 3 for special requirements for healthcare facilities. Due to federal reimbursement requirements, there are specific existing building issues that must be mitigated before receiving federal funds. These are reflected in Chapter 13 of the IFC, however, not all jurisdictions adopt this chapter. By referencing those requirements in the IEBC, we provide facilities with a greater chance at maintaining federal certification and at the same time ensure basic safety provisions for facilities that house fragile populations.

A companion proposal directly references chapter 11 of the IFC in all of the compliance methods. If it is more effective to have the actual technical requirements in this document, this change creates a place for those requirements to live.

The intent of Section 306.2 is to correlate with the federal regulations and the allowances in the IBC for fixed furniture in corridors where special considerations are met.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a pointer to the IEBC that indicates the allowances permitted for fixed furniture.
2018 International Existing Building Code

Add new text as follows:

**SECTION 306**

**SMOKE ALARMS**

### 306.1 Smoke Alarms
Where an alteration, addition, change of occupancy or relocation of a building is made to an existing building or structure of a Group R and I-1 occupancies, the existing building shall be provided with smoke alarms in accordance with Section 1103.8 of the International Fire Code or Section R314 of the International Residential Code.

**SECTION 307**

**CARBON MONOXIDE DETECTION**

### 307.1 Carbon monoxide alarms
Where an alteration, addition, change of occupancy or relocation of a building is made to Group I-1, I-2, I-4 and R occupancies, the existing building shall be provided with carbon monoxide alarms in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code.

**Exceptions:**

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

Delete without substitution:

### 502.6 Smoke alarms in existing portions of a building
Where an addition is made to a building or structure of a Group R or I-1 occupancy, the existing building shall be provided with smoke alarms in accordance with Section 1103.8 of the International Fire Code.

### 502.7 Carbon monoxide alarms in existing portions of a building
Where an addition is made to a building or structure of Group I-1, I-2, I-4 or R occupancy, the existing building shall be provided with carbon monoxide alarms in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code, as applicable.

**Exceptions:**

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

### 503.14 Smoke alarms
Individual sleeping units and individual dwelling units in Group R and I-1 occupancies shall be provided with smoke alarms in accordance with Section 1103.8 of the International Fire Code.

### 503.15 Carbon monoxide alarms
Carbon monoxide alarms shall be provided to protect sleeping units and dwelling units in Group I-1, I-2, I-4 and R occupancies in accordance with Section 1103.9 of the International Fire Code.

**Exceptions:**

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

### 803.4.3 Smoke alarms
Individual sleeping units and individual dwelling units in any work area in Group R and I-1 occupancies shall be provided with smoke alarms in accordance with the International Fire Code.

**Exception:** Interconnection of smoke alarms outside of the work area shall not be required.

**SECTION 804**

**CARBON MONOXIDE DETECTION**
804.1 Carbon monoxide alarms. Any work area in Group I-1, I-2, I-4 and R occupancies shall be equipped with carbon monoxide alarms in accordance with Section 1103.9 of the International Fire Code.

Exceptions:

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repair of plumbing or mechanical systems, other than fuel-burning appliances.

SECTION 1104
SMOKE ALARMS IN OCCUPANCY GROUPS R AND I-1

1104.1 Smoke alarms in existing portions of a building. Where an addition is made to a building or structure of a Group R or I-1 occupancy, the existing building shall be provided with smoke alarms as required by Section 1103.8 of the International Fire Code or Section R314 of the International Residential Code as applicable.

SECTION 1105
CARBON MONOXIDE ALARMS IN GROUPS I-1, I-2, I-4 AND R

1105.1 Carbon monoxide alarms in existing portions of a building. Where an addition is made to a building or structure of a Group I-1, I-2, I-4 or R occupancy, the existing building shall be equipped with carbon monoxide alarms in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code, as applicable.

Reason: Smoke alarms and carbon monoxide alarms are required for all the different options in the IEBC. It does not make sense to have the same requirements duplicated in the different options. Chapter 3 was created to address requirements that were applicable to all of the options. Therefore, this proposal places the requirement for smoke alarms and carbon monoxide alarms in Chapter 3 and deletes the specific requirements elsewhere in the code. This change also maintains the pointer to the fire code for these requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is just a relocation of the requirements into a single location.

Proposal # 5517
EB41-19

IEBC: 401.1.1 (New), 401.1.2 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@icc.e.org)

2018 International Existing Building Code

Revise as follows:

SECTION 401
GENERAL

401.1 Scope. Repairs shall comply with the requirements of this chapter. Repairs to historic buildings need only comply with Chapter 12.

Add new text as follows:

401.1.1 Partial reconstruction. Where damage from fire, earthquake, storm or a similar event has rendered one or more stories of a building, structure or portion thereof as unsafe, reconstruction of such areas shall meet the requirements for a Level 2 or 3 alteration, as applicable.

401.1.2 Complete reconstruction. Where damage from fire, earthquake, storm or similar event has demolished the building, structure, or a portion of a building or structure from the foundation to the roof, reconstruction of such areas shall be in accordance with the International Building Code.

Reason: There is a question as to when damage from a fire or other disaster destroying all or a good chunk of a building. Do you have to go back to IBC or can you build back the way it was? This concept is to try and separate repair from new construction requirements at a logical point. Note that this also helps people get the true value for reconstruction as the insurance industry may sometimes classify a new building (or a replacement of the large portion or an entire story) as a repair and funding is limited.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is intended as a clarification of requirements.
2018 International Existing Building Code

Add new text as follows:

402 Guards

An existing guard that is unable to resist a concentrated load of 200 pounds (0.89 kN) shall be repaired with like materials.

Work on an existing guard shall include augmenting the guard in accordance with the International Building Code where the height of the guard is one of the following:

1. Less than 36” above walking surfaces.
2. Less than 30” above the leading edges of stair treads.

404 Guards

Existing guards shall comply with the strength and height requirements of 402.2.

702 Guards

Guards shall comply with Sections 702.7.1 through 702.7.3, as applicable.

702.7 Minimum requirements. Existing guards shall be altered, augmented or replaced in accordance with the International Building Code where such guards are unable to resist a concentrated load of 200 pounds (0.89 kN), or the height of the guard is one of the following:

1. Less than 36” above walking surfaces,
2. Less than 30” above the leading edges of stair treads.

702.7.2 Elements of an existing guard. The alteration of elements of an existing guard with new elements of the same design shall maintain the guard’s strength and height.

702.7.3 New and reconfigured guards. New guards and existing guards that are augmented or otherwise reconfigured, shall comply with the International Building Code.

Revise as follows:

802.5.1 Minimum requirement. Where required. Every portion of a floor, such as a balcony or a loading dock, that is more than 30 inches (762 mm) above the floor or grade below and is not provided with guards, or those in which the existing guards are judged to be in danger of collapsing, shall be provided with guards. Guards shall be located along open-sided walking surfaces where required in accordance with the International Building Code. Where a required guard does not exist, a new guard shall be provided.

805.11 Guards. The requirements of Sections 805.11.1 and 805.11.2 Section 802.5 shall apply to guards from the work area floor to, and including, the level of exit discharge but shall be confined to the egress path of any work area.

Delete without substitution:

805.11.1 Minimum requirement. Every open portion of a stairway, landing, or balcony that is more than 30 inches (762 mm) above the floor or grade below and is not provided with guards, or those portions in which existing guards are judged to be in danger of collapsing, shall be provided with guards.

805.11.2 Design. Guards required in accordance with Section 805.11.1 shall be designed and installed in accordance with the International Building Code.

Revise as follows:

1011.4.1 Means of egress for change to a higher-hazard category. Where a change of occupancy classification is made to a higher-hazard category (lower number) as shown in Table 1011.4, the means of egress shall comply with the requirements of Chapter 10 of the International Building Code.

Exceptions:

1. Stairways shall be enclosed in compliance with the applicable provisions of Section 903.1.
2. Existing in hazard categories 4 or 5, existing stairways including handrails and guards complying with the requirements of Chapter 9 shall be permitted for continued use subject to approval of the code official.
3. Any stairway replacing an existing stairway within a space where the pitch or slope cannot be reduced because of existing
4. Existing corridor walls constructed on both sides of wood lath and plaster in good condition or 1/2 inch-thick (12.7 mm) gypsum wallboard shall be permitted. Such walls shall either terminate at the underside of a ceiling of equivalent construction or extend to the underside of the floor or roof next above.

5. Existing corridor doorways, transoms and other corridor openings shall comply with the requirements in Sections 805.5.1, 805.5.2 and 805.5.3.

6. Existing dead-end corridors shall comply with the requirements in Section 805.6.

7. An existing operable window with clear opening area not less than 4 square feet (0.38 m²) and minimum opening height and width of 22 inches (559 mm) and 20 inches (508 mm), respectively, shall be accepted as an emergency escape and rescue opening.

Reason: This code change reduces reliance on determinations by the code official of unsafe conditions by providing baseline measurements. The code is currently vague about guard requirements, stating, for example, that, in a change of occupancy, a guard “shall be permitted for continued use subject to approval of the code official.” In 1203.10.1 Height, the code states: “Existing guards shall comply with the requirements of Section 704,” but 704 contains no mention of guard height.

Fall safety is considered an area of the I-Codes that is central to life safety. See IBC Section 1015, IRC Section R312, and IMC Sections 304.11 and 306.5.1. Notably, the IEBC also considers fall safety, but from windows only (IEBC 702.4).

While the IEBC generally adheres to the principle that existing construction may remain, there are some areas of the code that depart from this principle for good reasons. One of these reasons is that standards of safety have changed.

The average height of humans has been increasing in recent history, requiring a higher guard to protect against falling. Because this standard of safety has changed, it would make sense for the IEBC to address this area of the code for existing buildings.

The baseline guard heights we propose are 42” in high hazard category occupancies, 36” above walking surfaces, and 30” above the leading edges of stair treads. While the 42” guard height is provided in the IBC generally, there are situations where a lower guard height is allowed:

- A 36” guard height is allowed for guards at the end of aisles in assembly seating areas (1029.16.4), and in individual dwelling units in Group R-2 and R-3 occupancies not more than three stories (1015.3).
- A 34” guard height is allowed on the open side of stairs in in individual dwelling units in Group R-2 and R-3 occupancies.

Legacy codes provided a 30” guard height at stairs as late as 1985. This dimension was later changed to 34”.

Legacy codes also provided reduced minimum guard heights for existing buildings. For example: “Existing guardrails … which are at least 36 inches shall be permitted to remain.” Also: “Guardrails for stairways, exclusive of their landings, may have a height that is not less than 30 inches measured above the nosing of treads.” [v]

Existing sections 802.5 and 805.11 are also proposed to be amended in order to incorporate the proposed minimum guard height requirements, to simplify the language, and to remove an incorrect reference to loading docks. [v]

---

[i] “… over the last 150 years the average height of people in industrialized nations has increased approximately 10 centimeters (about four inches).” Scientific American “Why are we getting taller as a species?” June 29, 1998.

[ii] 1985 Uniform Building Code, Sections 3306(j) and 1711.

[iii] 1988 Uniform Building Code, Sections 3306(j) and 1711.

[iv] 1997 Uniform Code for Building Conservation, Section 405.2

[v] IBC 1015.2 Exception 1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

No cost increase. The proposed changes only clarify the intent of the code, enumerating baseline dimensions that have generally been enforced as determined by code officials.
EB43-19

IEBC®: [BS] 405.2.3.1, [BS] 405.2.3.3, 506.4.2, [BS] 1006.2

Proponent: David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 405.2.3.1 Evaluation. The building shall be evaluated by a registered design professional, and the evaluation findings shall be submitted to the code official. The evaluation shall establish whether the damaged building, if repaired to its predamage state, would comply with the provisions of the International Building Code for load combinations that include wind, flood or earthquake effects, except that the seismic forces shall be the reduced seismic forces.

[BS] 405.2.3.3 Extent of repair for noncompliant buildings. If the evaluation does not establish that the building in its predamage condition complies with the provisions of Section 405.2.3.1, then the building shall be retrofitted to comply with the provisions of this section. The wind loads and the flood loads for the repair and retrofit shall be those required by the building code in effect at the time of original construction, unless the damage was caused by wind, in which case the wind loads and flood loads shall be in accordance with the International Building Code. The seismic loads for this retrofit design shall be those required by the building code in effect at the time of original construction, but not less than the reduced seismic forces.

506.4.2 Snow, flood and wind loads. Where a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608, 1609 and 1612 of the International Building Code for the new risk category.

   Exception: Where the area of the new occupancy is less than 10 percent of the building area, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.

[BS] 1006.2 Snow, flood and wind loads. Where a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608, 1609 and 1612 of the International Building Code for the new risk category.

   Exception: Where the area of the new occupancy is less than 10 percent of the building area. The cumulative effect of occupancy changes over time shall be considered.

Reason: Currently the IEBC has no criteria for determining the extent of damage during an evaluation following flood damage, nor how repairs are to be performed for existing noncompliant buildings when due to flood loads. The changes to Sections 405.2.3.1 and 405.2.3.3 will clearly establish what is to be done when the structure is subject to flood damage and must be repaired.

The revisions to Sections 506.4.2 and 1006.2 reflect a concern that flood loads are not addressed when a change of occupancy occurs where the change is to a higher risk category.

Cost Impact: The code change proposal will increase the cost of construction
Sections 405.2.3.1 and 405.2.3.3. This revisions is a clarification of the code by inclusion of specific provisions for performing needed repairs to an existing building will simplify the process of gaining permits and performing the necessary repairs in accordance with the code. These revisions will not increase the cost of construction.

Sections 506.4.2 and 1006.2 will now require that when a change occupancy occurs that places the structure in a higher risk category that flood loads must be accounted for therefore this may increase the cost of construction as the IEBC does not typically address this issue currently.

Proposal # 5410
EB44-19

IEBC®: [BS] 405.2.4

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 405.2.4 Substantial structural damage to gravity load-carrying components. Gravity load-carrying components that have sustained substantial structural damage shall be rehabilitated to comply with the applicable provisions for dead, live, and live snow loads in the International Building Code. Snow loads shall be considered if the substantial structural damage was caused by or related to snow load effects. Undamaged gravity load-carrying components that receive dead, live or snow loads from rehabilitated components shall also be rehabilitated if required to comply with the design loads of the rehabilitation design.

Reason: What the proposal does: Includes the consideration of snow load effects whether or not the cause of substantial structural damage was related to snow load effects.

Summary of the current problem and why it's unacceptable: The current IEBC is written such that consideration of snow load effects are only included when the substantial structural damage was caused by or related to snow load effects. Snow loads share the same load path as other gravity loads and should be considered when rehabilitating gravity load-carrying components.

How the proposal solves it, in concept: The proposed language requires consideration of snow load effects for all instances of the rehabilitation of gravity load-carrying components after sustaining substantial structural damage.

Point by point explanation and rationale for each change: The current provision requires only dead and live loads be considered when rehabilitating the gravity load-carrying components of a building that have sustained substantial structural damage. This is true even though it is probable that in some cases live loads did not play any part in causing the damage. As such, rehabilitation of the structure should include all applicable gravity design loads so that the rehabilitated structure is in compliance with current load requirements for new construction required by the International Building Code.

Cost Impact: The code change proposal will increase the cost of construction
Cost impact is negligible - potential slight increase if the load combination using snow load controls member design.

Proposal # 5161
EB45-19
IEBC®: 405.2.5 (New)

Proponent: Gwenyth R. Searer, Wiss, Janney, Elstner Associates, Inc., representing myself (gsearer@wje.com)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code
Add new text as follows:

405.2.5 Disproportionate Upgrade Costs The scope of work required by Sections 405.2.2, 405.2.3, and 405.2.4 need not exceed the scope of work required by Section 405.2.1 by more than 20 percent in terms of cost.

Reason: Arthur Mellen Wellington once wrote that an engineer can do for a dollar what any fool can do for two. The structural upgrade triggers in the IEBC were expanded yet again last code cycle with the addition of a snow damage trigger and a disproportionate earthquake damage trigger. These triggers were added to the two substantial structural damage triggers that were already present. While triggers seem like a good idea in theory (i.e., while a big repair is being performed, why not upgrade the structure while everything is exposed?), upgrade triggers have been shown to discourage repairs and maintenance (ICBO, 1998) and to result in wildly disproportionate upgrade costs (Searer et al., 2006). After the 1989 Loma Prieta earthquake, the City of Oakland adopted upgrade triggers that were the inspiration of the triggers in the IEBC. The following occurred as a result of the triggers:

1) Costs to repair and upgrade the buildings were often many times the cost of repair-only.
2) Building owners were unable to fund the upgrades in many cases.
3) Buildings were left abandoned, in their damaged states, for many years -- some more than a decade.
4) Some engineers gamed the system, trying to make the calculated loss-of-capacity fall under or exceed the triggers, depending on what their clients wanted.
5) Engineers, building officials, and owners were unable to agree on how to compute loss-of-structural-capacity.
6) Litigation ensued.

Even today, there exist no commonly accepted standards for determining loss-of-capacity.

Design and implementation of mandatory system-wide upgrades is even more problematic. For example, consider an older three-story residential structure with tuck-under parking and a soft story. The gypsum board and stucco walls comprise the lateral force resisting structure. Suppose that this building was required to be seismically upgraded due to the substantial structural damage trigger. An experienced structural engineer would likely conclude that the most economical way to strengthen the structure would be to address the soft/weak story on the ground floor by adding plywood shear walls and possibly steel moment frames on the ground floor, but leaving the top two stories, which lack the soft/weak story conditions, unaltered. This would eliminate the hazard most likely by far to result in collapse of the structure for relatively little cost. However, since the R-value has been set so incredibly low in recent codes to discourage the use of gypsum board and stucco as lateral force resisting elements in new buildings, the substantial structural damage trigger would require seismic upgrade of all floors and possibly the foundations as well in this example. So the solution that a rational engineer would generally propose and the building official would generally accept for a voluntary seismic upgrade and even an upgrade required by a soft/weak story ordinance is precluded because the substantial structural damage trigger has no limits: it requires that the lateral force resisting system be brought to at least 75 percent of current code or repair of the building is not permitted. Further, it often makes little sense to spend very large sums of money on older existing buildings that in general have much smaller remaining useful lives than newer buildings.

Engineering is supposed to be about weighing costs and benefits, and making decisions that reduce risk and make economic sense. Simply requiring engineers (and the building owners that have to foot the bills) to upgrade the vast majority of the lateral force-resisting system (including undamaged elements) in a damaged building makes little engineering sense.

A much better way to address potential future hazards in existing building stock is to have a rational cut-off in the amount of money that needs to be spent on triggered upgrades. Building owners and engineers can then make informed decisions about where that money should be spent. In the example above, the knowledgeable engineer would likely recommend strengthening the ground floor, where the soft/weak conditions are present, and would be able to exclude the portions of the structure that do not make sense to strengthen (e.g., the upper two floors).

This cut-off would be similar to the ADA/accessibility 20-percent limit. Architects and building officials often deal with this limit in the alteration of
existing buildings. The trigger is both effective (i.e., it addresses problems with accessibility) and limited/reasonable (i.e., it cannot result in costs many times the cost of the alteration). The architect and the owner then make the decisions regarding which components of the building should be improved with respect to alterations while considering the available budget. If architects, building owners, and building officials can deal with reasonable limitations regarding accessibility like this, one would hope that engineers, building owners, and building officials should also be able to deal with a similar reasonable cap on the costs of structural upgrades.

**Cost Impact:** The code change proposal will decrease the cost of construction

Limiting the economic impact caused by the existing structural damage repair triggers will reduce the cost of construction.
IEBC®: 406.1.4 (New), 408.3 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Delete and substitute as follows:

406.1.4 Group I-2 receptacles. Receptacles in patient bed locations of Group I-2 that are not “hospital grade” shall be replaced with “hospital grade” receptacles, as required by NFPA 99 and Article 517 of NFPA 70.

406.1.4 Healthcare facilities. Portions of electrical systems being repaired in Group I-2, ambulatory care facilities and outpatient clinics shall comply with NFPA 99 requirements for repairs.

Add new text as follows:

408.3 Healthcare facilities. Portions of Medical Gas systems being repaired in Group I-2, ambulatory care facilities and outpatient clinics shall comply with NFPA 99 requirements for repairs.

Reason: NFPA 99 specifies broader requirements for electrical systems in existing buildings beyond just hospital grade receptacles in bed locations. This includes requirements tamperproof receptacles in pediatrics, and additional requirements for surgery. NFPA 99 defines requirements for existing facilities. In order to meet federal conditions of participation health care facilities must comply with the electrical systems and equipment and medical gas systems must be installed according to the requirements listed in NFPA 99, Health Care Facilities Code (K912, and K917). This change will align the electrical and medical gas (K909 and K910) systems installation requirements for Outpatient Clinics, Group B Ambulatory Care and Group I-2 facilities. NFPA 99 defines when repairs are made to these systems requirement for component replacement, means and methods of repairs and safety requirements.

NFPA 99 uses a risk based approach to system design, installation and maintenance in healthcare facilities (Group I-2 facilities, ambulatory care facilities and outpatient clinics). Four levels of systems categories are defined in NFPA 99, based on the risks to patients and caregivers in the facilities. The categories are as follows:

1. Category 1: Systems that are expected to be functional at all times. Failure of these systems is likely to cause major injury or death.

2. Category 2: Systems are expected to have a high level of reliability. Failures of these systems are likely to cause minor injury to patients or caregivers, however, limited short durations of equipment downtime can be tolerated. Category 2 systems are not critical for life support.

3. Category 3: Normal building system reliabilities are expected. Such systems support patient needs, but failure of such equipment or systems would not immediately affect patient care and are not critical for life support.

4. Category 4: Such systems have no impact on patient care and would not be noticeable to patients in the event of failure.

The category definitions apply to equipment and systems operations.

A risk assessment should be conducted to evaluate the risk to the patients, staff, and visitors in all healthcare facilities. These categories are not always aligned to occupancy classification. Potential examples of areas/systems and their categories of risk;

1. Ambulatory surgical center, where patients undergo general anesthesia, Category 1

2. Reconstructive surgeon’s office with general anesthesia, Category 1

3. Procedural sedation site for outpatient services, Category 2

4. Cooling systems in Houston, TX, Category 2

5. Cooling systems in Seattle, WA, Category 3

6. Heating systems in Chicago, IL Category 2

7. Dental office, no general anesthesia, Category 3

8. Typical doctor’s office/exam room, Category 4

9. Group I-2 Condition 2 facilities most systems would be Category 1
This approach more closely aligns system design, performance and maintenance to the safety risk to the public. It does not create significant additional costs.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change aligns with existing federal requirements for the healthcare industry.
EB47-19

IEBC®: 406.1.4 (New), 802.3 (New), 805.4.1.2 (New), 1301.6.4 (New), 1301.6.21 (New), 1301.6.21.1 (New), 1301.6.21.1.1 (New), 1301.6.21.2 (New), TABLE 1301.6.21.2 (New), 1301.6.21.2.1 (New), 1301.6.21.3 (New), 1301.6.21.3.1 (New), 1301.17 (New), TABLE 1301.17

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

406.1.4 Group I-2 receptacles. Receptacles in patient care recipient bed locations of Group I-2 that are not “hospital grade” shall be replaced with “hospital grade” receptacles, as required by NFPA 99 and Article 517 of NFPA 70.

802.3 Smoke compartments. In Group I-2 occupancies where the work area is on a story used for sleeping rooms for more than 30 patient care recipients, the story shall be divided into not less than two compartments by smoke barrier walls in accordance with Section 407.5 of the International Building Code as required for new construction.

805.4.1.2 Group I-2. In buildings of Group I-2 occupancy, any patient care recipient sleeping room or suite of patient care recipient rooms greater than 1,000 square feet (93 m²) within the work area shall have not fewer than two egress doorways.

1301.6.4 Tenant and dwelling unit separations. Evaluate the fire-resistance rating of floors and walls separating tenants, including dwelling units, and not evaluated under Sections 1301.6.3 and 1301.6.5. Group I-2 occupancies shall evaluate the rating of the separations between patient care recipient sleeping rooms.

Under the categories and occupancies in Table 1301.6.4, determine the appropriate value and enter that value in Table 1301.7 under Safety Parameter 1301.6.4, Tenant and Dwelling Unit Separation, for fire safety, means of egress, and general safety.

1301.6.21 Patient care recipient ability, concentration, smoke compartment location and ratio to attendant. In I-2 occupancies, the ability of patient care recipients, their concentration and ratio to attendants shall be evaluated and applied in accordance with this section. Evaluate each smoke compartment using the categories in Sections 1301.6.21.1, 1301.6.21.2 and 1301.6.21.3 and enter the value in Table 1301.7. To determine the safety factor, multiply the three values together; if the sum is 9 or greater, compliance has failed.

1301.6.21.1 Patient care recipient ability for self-preservation. Evaluate the ability of the patient care recipients for self-preservation in each smoke compartment in an emergency. Under the categories and occupancies in Table 1301.6.21.1, determine the appropriate value and enter that value in Table 1301.7 under Safety Parameter 1301.6.21.1, Patient care recipient Ability for Self-preservation, for means of egress and general safety.

<table>
<thead>

<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-2</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

1301.6.21.1 Categories: The categories for patient care recipient ability for self-preservation are:

1. Category a—(mobile) Patients Care recipients are capable of self-preservation without assistance.
2. Category b—(not mobile) Patients Care recipients rely on assistance for evacuation or relocation.
3. Category c—(not movable) Patients Care recipients cannot be evacuated or relocated.

1301.6.21.2 Patient care recipient concentration. Evaluate the concentration of patients in each smoke compartment under Section 1301.6.21.2. Under the categories and occupancies in Table 1301.6.21.2 determine the appropriate value and enter that value in Table 1301.7 under Safety Parameter 1301.6.21.2, Patient Care Recipient Concentration, for means of egress and general safety.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>I-2</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

1301.6.21.2 Categories: The categories for patient care recipient concentration are:
1. Category a—smoke compartment has 1 to 10 patients-care recipients.
2. Category b—smoke compartment has more than 10 to 40 patients-care recipients.
3. Category c—smoke compartment has more than 40 patients-care recipients.

1301.6.21.3 Attendant-to-patient Attendant-to-care recipient ratio. Evaluate the attendant-to-patient attendant-to-care recipient ratio for each compartment under Section 1301.6.21.3. Under the categories and occupancies in Table 1301.6.21.3 determine the appropriate value and enter that value in Table 1301.7 under Safety Parameter 1301.6.21.3, Attendant to patient Attendant-to-care recipient Ratio, for means of egress and general safety.

### TABLE 1301.6.21.3 ATTENDANT-TO-PATIENT ATTENDANT-TO-CARE RECIPIENT RATIO VALUES

**Building score—total value**

* * * *No applicable value to be inserted.

a. Only applicable to Group I-2 occupancies.

**Reason:**
The purpose of this proposal is to coordinate the terminology for healthcare in the IBC and IFC with the IEBC. Care recipient is more appropriate when speaking about the persons receiving care in nursing homes and hospitals.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This is editorial.

Proposal # 4255
EB48-19
IEBC®: 501.3 (New), 1301.3.2

Proponent: Eirene Knott, representing Myself (Eirene.Knott@brrarch.com)

2018 International Existing Building Code
Add new text as follows:

501.3 Compliance with other codes In accordance with Section 301.3.1, this provisions of Chapter 11 of the International Fire Code shall also apply to this compliance method.

Revise as follows:

1301.3.2 Compliance with other codes. Buildings that are evaluated in accordance with this section shall comply with Chapter 11 of the International Fire Code and the International Property Maintenance Code.

Reason: While Section 301.3.1 and 1301.3.2 point the user to the IFC for use with the prescriptive and performance compliance methods, most users will assume that all the provisions in the IFC will apply under these methods. If the provisions of Chapter 11 of the IFC can be met, along with the provisions of either Chapter 5 for the prescriptive method or Chapter 13 for the performance method, then the building is compliant. This code change is simply adding pointers to the appropriate sections of the IFC for compliance under the prescriptive method.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This code change is adding language to provide a pointer to the prescriptive provisions of the IFC for existing buildings that is already referenced in Section 301.3.1.

Proposal # 5544

EB48-19
EB49-19
IEBC®: 501.3 (New), SECTION 706 (New), 706.1 (New), 807.3 (New), 809.2 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code
Add new text as follows:

501.3 Healthcare facilities. In Group I-2 facilities, ambulatory care facilities and outpatient clinics, any altered or added portion of an existing electrical or medical gas systems shall be required to meet installation and equipment requirements in NFPA 99.

SECTION 706
ELECTRICAL

706.1 Healthcare facilities. In Group I-2 facilities, ambulatory care facilities and outpatient clinics, any altered portion of an existing electrical systems shall be required to meet installation and equipment requirements in NFPA 99.

807.3 Healthcare facilities. In Group I-2 facilities, ambulatory care facilities and outpatient clinics, any added portion of an existing electrical systems shall be required to meet installation and equipment requirements in NFPA 99.

809.2 Healthcare facilities. In Group I-2 facilities, ambulatory care facilities and outpatient clinics, any added portion of an existing medical gas systems shall be required to meet installation and equipment requirements in NFPA 99.

Reason: In order to meet federal conditions of participation health care facilities must comply with the electrical systems and equipment and medical gas systems and equipment must be installed according to the requirements listed in NFPA 99, Health Care Facilities Code (K 323, K901, K902, K903, K904, K905, K909, K910, K913, K915, K916 K923, K925 and K927). This change will align the electrical and medical gas systems installation requirements for Outpatient Clinics, Group B Ambulatory Care and Group I-2 facilities. NFPA 99 uses a risk based approach to system design, installation and maintenance in healthcare facilities (Group I-2 facilities, ambulatory care facilities and outpatient clinics). Four levels of systems categories are defined in NFPA 99, based on the risks to patients and caregivers in the facilities. The categories are as follows:

(1) Category 1: Systems that are expected to be functional at all times. Failure of these systems is likely to cause major injury or death.

(2) Category 2: Systems are expected to have a high level of reliability. Failures of these systems are likely to cause minor injury to patients or caregivers, however, limited short durations of equipment downtime can be tolerated. Category 2 systems are not critical for life support.

(3) Category 3: Normal building system reliabilities are expected. Such systems support patient needs, but failure of such equipment or systems would not immediately affect patient care and are not critical for life support.

(4) Category 4: Such systems have no impact on patient care and would not be noticeable to patients in the event of failure.

The category definitions apply to equipment and systems operations.

A risk assessment should be conducted to evaluate the risk to the patients, staff, and visitors in all healthcare facilities. These categories are not always aligned to occupancy classification. Potential examples of areas/systems and their categories of risk;

(1) Ambulatory surgical center, where patients undergo general anesthesia, Category 1

(2) Reconstructive surgeon’s office with general anesthesia, Category 1

(3) Procedural sedation site for outpatient services, Category 2

(4) Cooling systems in Houston, TX, Category 2

(5) Cooling systems in Seattle, WA, Category 3

(6) Heating systems in Chicago, IL Category 2

(7) Dental office, no general anesthesia, Category 3

(8) Typical doctor’s office/exam room, Category 4
Group I-2 Condition 2 facilities most systems would be Category 1

This approach more closely aligns system design, performance and maintenance to the safety risk to the public. It does not create significant additional costs.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This change aligns with existing federal requirements for the healthcare industry.
2018 International Existing Building Code

Add new text as follows:

**SECTION 502**

**Repairs**

502.1 **Scope.** Repairs, as defined by Chapter 2, include the patching or restoration or replacement of damaged materials, elements, equipment or fixtures for the purpose of maintaining such components in good or sound condition with respect to existing loads or performance requirements.

502.2 **Application.** Repairs shall comply with the provisions of Chapter 4.

**SECTION 602**

**Repairs**

602.1 **Scope.** Repairs, as defined by Chapter 2, include the patching or restoration or replacement of damaged materials, elements, equipment or fixtures for the purpose of maintaining such components in good or sound condition with respect to existing loads or performance requirements.

602.2 **Application.** Repairs shall comply with the provisions of Chapter 4.

1301.2.5 **Repairs.** Repairs shall comply with the provisions of Chapter 4.

**Reason:** With the 2018 IEBC providing a stand alone chapter specific to repairs, some of the pointers that previously existed appear to have been lost. This code change is providing pointers for all three compliance methods to Chapter 4 for how repairs are to be provided.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost impact with this code change as it is only adding text for clarification purposes.
2018 International Existing Building Code

SECTION 502
ADDITIONS

502.8 Additions to Group E facilities. For additions to Group E occupancies, storm shelters shall be provided in accordance with Section 1106.1.

Add new text as follows:

502.9 Enhanced classroom acoustics. In Group E occupancies, enhanced classroom acoustics shall be provided in all classrooms in the addition with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

SECTION 503
ALTERATIONS

503.17 Enhanced classroom acoustics. In Group E occupancies, where the work area exceeds 50 percent of the building area, enhanced classroom acoustics shall be provided in all classrooms with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

SECTION 506
CHANGE OF OCCUPANCY

506.5 Enhanced classroom acoustics. In Group E occupancies, where the work area exceeds 50 percent of the building area, enhanced classroom acoustics shall be provided in all classrooms with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

SECTION 903
BUILDING ELEMENTS AND MATERIALS

903.4 Enhanced classroom acoustics. In Group E occupancies, where the work area is a Level 3 alteration, enhanced classroom acoustics shall be provided in all classrooms with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

SECTION 1011
CHANGE OF OCCUPANCY CLASSIFICATION

1011.3 Interior finish. In areas of the building undergoing the change of occupancy classification, the interior finish of walls and ceilings shall comply with the requirements of the International Building Code for the new occupancy classification.

1011.4 Enhanced classroom acoustics. In Group E occupancies, where the work area is a Level 3 alteration, enhanced classroom acoustics shall be provided in all classrooms with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

SECTION 1101
GENERAL

1101.3 Other work. Any repair or alteration work within an existing building to which an addition is being made shall comply with the applicable requirements for the work as classified in Chapter 6.

1101.4 Enhanced classroom acoustics. In Group E occupancies, enhanced classroom acoustics shall be provided in all classrooms in the addition with a volume of 20,000 cubic feet (565 m$^3$) or less. Enhanced classroom acoustics shall comply with the reverberation time in Section 808 of ICC A117.1.

Reason: This proposal sets up a new section in the Chapter for Interior Environments; next to the section for sound transmission in residential occupancies. This section is proposed here and not in Chapter 11 because of the benefits of these provisions for all young children – thus following...
the codes history of mainstreaming' requirements that may be related to accessibility, but apply broadly. Research shows that good classroom acoustics are essential to support language acquisition and learning for all children, particularly younger children. For children who have hearing loss and those who use cochlear implants there is no substitute for a good acoustic environment. Assistive technologies typically only amplify the teacher and do not amplify discussions among children or between the teacher and individual child. Children with disabilities not related to hearing, such as autism and learning disabilities may be adversely affected by high ambient noise levels. Students that use a different language at home will also be able to listen more closely to fully understand the teacher and benefit from conversation among peers. Teachers report that a good acoustic environment actually assists in controlling the classroom, reducing the need to raise their voices, and promotes more civil behavior among students. Thus, good acoustic and low background noise in a classroom benefits everyone!

The standard size elementary classroom in the United States holds 25 to 30 students. Many states specify the minimum size at 700 sq.ft. – assuming 20 children in a room. The recommended size for a self-contained classroom is 800 to 960 sq.ft. for grade school; 700 to 840 sq.ft. for secondary school. Some researchers recommend up to 54 sq.ft. per child as optimum – 1620 sq.ft. for a 30 child classroom. Classrooms that are used for activities such as band, orchestra, choir or gym are significantly larger. Some lecture rooms in colleges are large enough to accommodate several hundred students.

The new technical criteria for classroom acoustics in the 2017 ICC A117.1 are limited to classrooms with a size under 20,000 cubic feet; assuming a 10 foot ceiling height, classrooms that are 2000 sq.ft. or less. While acoustics may be important to these larger classrooms, the criteria in ICC A117.1 Section 808 are intended to be applicable to standard size self-contained classrooms. This criteria are also not intended to apply to ancillary learning spaces, such as individual tutoring spaces, or other spaces where students may be, such as corridors or cafeterias.

Technical criteria includes a maximum reverberation time – achieved through either a performance or prescriptive method. The criteria also considers other sound sources – ambient sound and sound sources inside and outside the classrooms.

Below is the text in the IBC and A117.1 for reference.

2021 IBC

SECTION 1207 ENHANCED CLASSROOM ACOUSTICS

1207.1 General. Enhanced classroom acoustics, where required in this section, shall comply with Section 808 of ICC A117.1.

1207.2 Where required. In Group E occupancies, enhanced classroom acoustics shall be provided in all classrooms with a volume of 20,000 cubic feet or less.

2017 ICC A117.1

SECTION 808

ENHANCED ACOUSTICS FOR CLASSROOMS

808.1 General. Classrooms not exceeding 20,000 cubic feet (565 m3) and required to provide enhanced acoustics shall comply with Section 808.

808.2 Reverberation time. Classroom reverberation times shall comply with either Section 808.2.1 or Section 808.2.2, depending on the size of the room.

808.2.1 Performance method. For each of the octave frequency bands with center frequencies of 500, 1000, and 2000 Hz, the reverberation time (T60) shall not exceed the times specified below:

1. 0.6 seconds in classrooms with volumes up to and including 10,000 cubic feet (285 m3).

2. 0.7 seconds in classrooms with volumes of more than 10,000 cubic feet (285 m3), but less than 20,000 cubic feet (566 m3).

Reverberation times shall apply to fully-furnished, unoccupied classrooms. Reverberation times shall be field verified via measurements over a minimum 20 dB decay in each octave frequency band in accordance with ASTM E2235 listed in Section 106.2.13.

808.2.2 Prescriptive method. The Noise Reduction Coefficient (NRC) ratings for floor, wall and ceiling surface finishes shall conform to the following equations:

For a classroom with a volume less than or equal to 10,000 cubic feet (285 m3):

\[(\text{NRCFloor x SFloor}) + (\text{NRCCeiling x SCeiling}) + (\text{NRCWall x SWall}) \leq \frac{\text{Volume}}{12}\]
For a classroom with a volume between 10,000 cubic feet (285 m³) and 20,000 cubic feet (565 m³):

\[(\text{NRCFloor} \times \text{SFloor}) + (\text{NRCCeiling} \times \text{SCeiling}) + (\text{NRCWall} \times \text{SWall}) + \frac{\text{Volume}}{14}\]

Where:

- NRCFloor = NRC rating of the floor finish material
- SFloor = floor area in square feet
- NRCCeiling = NRC rating of the ceiling finish material
- SCeiling = ceiling area in square feet
- NRCWall = NRC rating of the wall acoustical treatment
- SWall = wall treatment area in square feet
- Volume = room volume in cubic feet

Where a floor, ceiling or wall has multiple surface finishes, the NRC x S product for each surface finish shall be added to the left side of the equation.

**808.3 Ambient sound level.** Classroom ambient sound levels shall comply with Sections 808.3.1 and 808.3.2. Ambient sound levels from sound sources outside and inside the classroom shall be evaluated individually. The greatest one-hour averaged sound levels shall be evaluated at the loudest usable location in the room at a height of 36 inches (915 mm) to 42 inches (1065 mm) above the floor and no closer than 36 inches (915 mm) from any wall, window or object. The ambient sound level limits shall apply to fully-furnished, unoccupied classrooms, and with only permanent HVAC, electrical and plumbing systems functioning. Classroom equipment, including, but not limited to, computers, printers and fish tank pumps shall be turned off during these measurements.

**808.3.1 Sound sources outside of the classroom.** Classroom ambient sound levels shall not exceed 35 dBA and 55 dBC due to intruding noise from sound sources outside of the classroom, whether from the exterior or from other interior spaces.

**808.3.2 Sound sources inside the classroom.** Classroom ambient sound levels shall not exceed 35 dBA and 55 dBC for noise from sound sources inside the classroom.

**Cost Impact:** The code change proposal will increase the cost of construction. There will be acoustic requirements for classrooms, but not all spaces in new schools. Since this encompasses such a broad range of options to comply, the cost may be limited by design choices.
Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code
Revise as follows:

SECTION 502
ADDITIONS

502.7 Carbon monoxide alarm detection in existing portions of a building. Where an addition is made to a building or structure of Group I-1, I-2, I-4 or R occupancy and in classrooms in Group E occupancies, the existing building shall be provided with carbon monoxide alarm detection in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code, as applicable.

Exceptions:

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

SECTION 1105
CARBON MONOXIDE ALARMS IN GROUPS I-1, I-2, I-4 AND R DETECTION

1105.1 Carbon monoxide alarm detection in existing portions of a building. Where an addition is made to a building or structure of a Group I-1, I-2, I-4 or R occupancy and in classrooms in Group E occupancies, the existing building shall be equipped with carbon monoxide alarm detection in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code, as applicable.

SECTION 503
ALTERATIONS

503.15 Carbon monoxide alarm detection. Carbon monoxide alarms shall be provided to protect sleeping units and dwelling units. Any work area in Group I-1, I-2, I-4 and R occupancies, and classrooms in Group E occupancies shall be equipped with carbon monoxide detection in accordance with Section 1103.9 of the International Fire Code.

Exceptions:

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

SECTION 804
CARBON MONOXIDE DETECTION

804.1 Carbon monoxide alarm detection. Any work area in Group I-1, I-2, I-4 and R occupancies, and classrooms in Group E occupancies shall be equipped with carbon monoxide alarm detection in accordance with Section 1103.9 of the International Fire Code.

Exceptions:

1. Work involving the exterior surfaces of buildings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of porches or decks.
2. Installation, alteration or repairs of plumbing or mechanical systems, other than fuel-burning appliances.

Reason: Section 502.7 and 1105.1 deal with additions, and Section 503.15 and 804.1 deal with alterations. The intent of this proposal is correlation between the IEBC and the IFC. This proposal accomplishes two things. First it correlates the occupancies in which carbon monoxide detection is required in IFC Sections 915 and 1103.9, which essentially adds classrooms in Group E occupancies. Second, it changes references from “carbon monoxide alarms” to “carbon monoxide detection”. This change in terminology will not preclude carbon monoxide alarms from being provided in applications for which they are listed, but better reflects terminology used in the IFC.
The exceptions are proposed to be deleted from the additions section of the prescriptive method rather than added additions chapter in the work area method since the exceptions are not needed for additions.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will increase the cost of construction
The increased cost will be for providing carbon monoxide detection when classrooms in Group E occupancies are covered by these code sections.

Proposal # 4307
EB53-19

IEBC®: (New), [BS] 503.3

Proponent: Michael Fillion, representing National Council of Structural Engineers Association (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new definition as follows:

[BS] ROOF COVERING. The covering applied to the roofdeck for weather resistance, fire classification or appearance.

Revise as follows:

[BS] 503.3 Existing structural elements carrying gravity load. Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose gravity load-carrying capacity is decreased as part of the alteration shall be shown to have the capacity to resist the applicable design dead, live and snow loads including snow drift effects required by the International Building Code for new structures.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is due entirely to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering. This exception shall not apply where insulation is added to the roof assembly.

Reason: In many re-roofing projects, insulation and membrane are placed over an existing roof covering. The weight of the insulation and membrane are usually less than 3 pounds per square foot (0.1437 kN/m²). It has been our observation that some design professionals and building officials are using this exception when insulation is added with the new second layer of roof covering. Addition of insulation increases the thermal resistance (R-value) resulting in a higher Thermal Factor, Ct, which will increase the design roof snow load. Because of this oversight in some instances, we feel it is important to include the IBC roof covering definition and to make it clear that adding insulation is not included in Exception #2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The intent of this code change proposal is for clarification

Proposal # 5333
EB54-19

IEBC®: [BS] 503.4

Proponent: Ali Fattah, City of San Diego, representing City of San Diego (afattah@sandiego.gov)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 503.4 Existing structural elements carrying lateral load. Except as permitted by Section 503.13, where the alteration increases design lateral loads, results in a prohibited structural irregularity as defined in ASCE 7, or decreases the capacity of any existing lateral load-carrying structural element, the structure of the altered building or structure shall meet the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exception:

1. Any existing lateral load-carrying structural element whose demand-capacity ratio with the alteration considered is not more than 10 percent greater than its demand-capacity ratio with the alteration ignored shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities shall account for the cumulative effects of additions and alterations since original construction.

2. Buildings in which the increase in the demand capacity ratio is due entirely to the addition of roof top supported mechanical equipment individually having an operating weight less than 400 lb and when the total additional weight of all roof top equipment placed after initial construction of the building is less than 10% of the roof design dead load. For purposes of this exception roof shall mean the roof level above a particular story.

3. Replacement of rooftop mechanical equipment where the new equipment has an operating weight equal to or less that the existing equipment to be replaced.

Reason: Building owners and tenants frequently add or replace roof top mechanical equipment as a part of interior tenant improvement work. Most projects only consider the gravity load effects and ignore contributions to roof dead load and as a result increases to the seismic weight that needs to be resisted by the seismic force resisting system. Additionally, engineers performing the structural design for new buildings determine the total accumulated operating weight of roof top equipment and divide the load by the area of the roof and add the weight in psf to the seismic dead weight. As a consequence, new building designs do not account for localized impacts of roof top equipment. This code change merely codifies current practice. ASCE 7 does not require that anchorage and bracing be determined for supported equipment having a weight of 400 lb or less. Most building departments I polled and review staff indicated that the vast majority of engineers focus merely on support and anchorage and typically do so after the first review cycle since only mechanical plans are provided.

Cost Impact: The code change proposal will decrease the cost of construction

The proposal seeks to limit the need for structural analysis of the lateral force resisting system, and to limit the need for a structural upgrade due to the possible increase in seismic forces and thus the demand capacity ratio, to cases where there is a need to add significantly heavy equipment such as a building maintenance equipment (BMU) to wash and replace windows on a high rise or heavy cooling towers. Currently there is not consistency of enforcement where engineers make a judgement call to not verify compliance and often times the building official only reviews support and anchorage for example on a wood retail building or a concrete tilt-up building.

Proposal # 5198
EB55-19
IEBC®: 202 (New), [BS] 503.3

(JoeCainPE@gmail.com)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code
Add new definition as follows:

PHOTOVOLTAIC PANEL SYSTEM. A system that incorporates discrete photovoltaic panels, that converts solar radiation into electricity, including rack support systems.

Revise as follows:

[BS] 503.3 Existing structural elements carrying gravity load. Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose gravity load-carrying capacity is decreased as part of the alteration shall be shown to have the capacity to resist the applicable design dead, live and snow loads including snow drift effects required by the International Building Code for new structures.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is due entirely to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering.

3. Buildings in which the increased dead load is due entirely to the addition of a photovoltaic panel system weighing 4 pounds per square foot (0.1916 kN/m²) or less over an existing single layer of roof covering.

Reason: Building codes commonly allow a second layer of roof covering such as composition shingle to be installed over a first layer of roof covering, without any structural analysis. Residential PV systems on high-slope roofs typically have a unit weight approximately the same as a second layer of roof covering.

The added definition of photovoltaic panel system is the same as found in the IBC.

Cost Impact: The code change proposal will decrease the cost of construction

By providing exemption from structural engineering analysis for simple cases, this proposal will decrease the soft cost of some renewable energy systems.
EB56-19

IEBC®: (New), [BS] 503.4

Proponent: Ali Fattah, City of San Diego, representing City of San Diego (afattah@sandiego.gov)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new definition as follows:

[BS] PHOTOVOLTAIC PANEL SYSTEM. A system that incorporates discrete photovoltaic panels, that converts solar radiation into electricity, including rack support systems.

Revise as follows:

[BS] 503.4 Existing structural elements carrying lateral load. Except as permitted by Section 503.13, where the alteration increases design lateral loads, results in a prohibited structural irregularity as defined in ASCE 7, or decreases the capacity of any existing lateral load-carrying structural element, the structure of the altered building or structure shall meet the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exception:

1. Any existing lateral load-carrying structural element whose demand-capacity ratio with the alteration considered is not more than 10 percent greater than its demand-capacity ratio with the alteration ignored shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities shall account for the cumulative effects of additions and alterations since original construction.

2. The installation of rooftop photovoltaic panel systems where the additional roof dead load due to the system, including ballast where applicable, does not exceed 5 psf and 10% of the dead load of the existing roof. For purposes of this exception roof shall mean the common roof above a common story.

Reason: The IEBC includes a needed exception to exempt existing buildings undergoing alterations from compliance with more current seismic requirements in IBC chapter 16. The existing exception uses demand/capacity ratios (DCR) to identify a threshold below which the alteration is not deemed to be significant enough to require an evaluation and possible upgrade of the existing lateral force resisting system. Demand equates to the load applied to the lateral force resisting system and capacity equates the strength of the lateral force resisting system to resist the lateral load. Demand can be impacted by an increase in gravity load, an alteration that redirects load to existing elements in addition to the loads they resist prior to the alteration (such as for example force transfer around and due to a large floor/roof opening. The capacity of existing lateral force resisting elements can be impacted by alterations that cut into the elements such as for example reducing the length of a shearwall. Roof top solar photovoltaic systems, and especially those with ballast, may increase the demand capacity ratio of lateral force resisting systems due to the location of the installation relative to the existing lines of resistance below the roof. For example a building that includes lateral force resisting systems at the interior of the building in addition to those at the exterior may cause an in creased DCR at the interior shearwalls due additional tributary loads. As a consequence and without the proposed code change the installation of a rooftop solar system would require that a qualified engineer identify the existing lateral force resisting system (possibly without plans), determine it's capacity and determine the demand and thus demonstrate that the DCR increase is not increased by more than 10%.

This requirement imposes a significant burden on buildings constructed with light framed wood construction since unlike other buildings they do not incorporate heavier concrete or steel floors and roofs or heavier concrete or masonry exterior walls. Heavier walls and roofs will allow the roof top installations to easily satisfy the DCR limit.

While unlike Section 503.3 exception 2 where 3 psf is used this code change uses 5 psf as a load threshold to allow for small-ballasted systems to benefit from proposed exception 2. There is no published data demonstrating that alterations involving the installation of rooftop solar photovoltaic caused a life-safety hazard due to a seismic event. It would be difficult to explain to a building owner that the installation of a rooftop solar system necessitates $2,000 or more in engineering costs and possible upgrades to the lateral force resisting system. ASCE 7 as well as the IBC recognizes that solar voltaic systems are unique and allow seismic force resistance through friction and allow discounting of the roof live load under the rack-mounted assemblies. This proposed code change offers a similar and reasonable accommodation to light weight components that are hand carried on to a roof and which occupy a portion of the roof.

Cost Impact: The code change proposal will decrease the cost of construction

The proposed code change may eliminate the need to develop detailed structural plans to demonstrate the capacity of the existing lateral force resisting system as well as lateral force resisting system upgrades.
EB57-19
IEBC®: [BS] 503.12, [BS] 706.3.2

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 503.12 Roof diaphragms resisting wind loads in high-wind regions. Where the intended alteration requires a permit for reroofing and involves removal of roofing materials from more than 50 percent of the roof diaphragm of a building or section of a building located where the ultimate design wind speed is greater than 115 mph (51 m/s) in accordance with Figure 1609.3(1) of the International Building Code or in a special wind region as defined in Section 1609 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof-to-wall connections shall be evaluated for the wind loads specified in Section 1609 of the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in Section 1609 of the International Building Code.

Exception: Buildings that have been demonstrated to comply with the wind load provisions in ASCE 7-88 or later editions up to and including ASCE 7-2016.

[BS] 706.3.2 Roof diaphragms resisting wind loads in high-wind regions. Where roofing materials are removed from more than 50 percent of the roof diaphragm or section of a building located where the ultimate design wind speed, $V_{ult}$, determined in accordance with Figure 1609.3(1) of the International Building Code, is greater than 115 mph (51 m/s) or in a special wind region, as defined in Section 1609 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof-to-wall connections shall be evaluated for the wind loads specified in the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in the International Building Code.

Exception: Buildings that have been demonstrated to comply with the wind load provisions in ASCE 7-88 or later editions up to and including ASCE 7-2016.

Reason: Provides an exception for buildings that are known to have been designed to comply with, or buildings in which the roof diaphragms can be demonstrated to resist, comprehensive design wind load provisions.

As currently written, this section of the code applies equally to the reroofing of all buildings that meet the reroofing percentages and the location triggers, regardless of when the buildings were constructed.

The proposal adds an exception wherein buildings are exempt from the provision when it is known to comply with, or can be demonstrated to comply with, the comprehensive design wind load provisions that have been included in ASCE 7 since 1988.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Proposal will reduce the number of instances of when building diaphragms need to have an engineering evaluation done.

Staff Analysis: Note that the 1988 through 1995 editions are referenced in various years of the legacy codes (pre I-codes), and the 1988 through the 2016 are referenced in various years of the I-codes.
EB58-19
IEBC®: [BS] 503.12, [BS] 706.3.2

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 503.12 Roof diaphragms resisting wind loads in high-wind regions. Where the intended alteration requires a permit for reroofing and involves removal of roofing materials from more than 50 percent of the roof diaphragm of a building or section of a building located where the ultimate design wind speed is greater than 445-130 mph (54-58 m/s) in accordance with Figure 1609.3(1) of the International Building Code or, and is in a special wind-hurricane-prone region as defined in Section 1609.202 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof-to-wall connections shall be evaluated for the wind loads specified in Section 1609 of the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in Section 1609 of the International Building Code.

[BS] 706.3.2 Roof diaphragms resisting wind loads in high-wind regions. Where roofing materials are removed from more than 50 percent of the roof diaphragm or section of a building located where the ultimate design wind speed, $V_{ul}$, determined in accordance with Figure 1609.3(1) of the International Building Code, is greater than 445-130 mph (54-58 m/s) or and is in a special wind-hurricane-prone region, as defined in Section 1609.202 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof-to-wall connections shall be evaluated for the wind loads specified in the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in the International Building Code.

Reason: What the proposal does: Changes the triggering wind speed to that which reasonably coincides with a value above which past experience indicates there is a substantial risk of diaphragm or uplift damage and/or failures in hurricane-prone regions. Also, deletes locations in special wind regions as a trigger and replaces it with locations in hurricane-prone regions where damage from uplift on roofs is a known problem.

Summary of the current problem and why it’s unacceptable: Design wind speeds modestly exceeding 115 mph, regardless of geographical location, are not appropriate triggers because there is no historical data indicating that such wind speeds pose any exceptional risk of building diaphragm damage or failure. Wind speeds in special wind regions can vary widely from something less than 115 mph to something much greater than 115 mph. The way the provision is currently written, a building located in a special wind region where the ultimate design wind speed is less than or equal to 115 mph, i.e., exposed to no exceptional wind demands, would be subject to these requirements. Furthermore, there is no historical evidence indicating that diaphragm deficiencies pose any extraordinary threat outside of hurricane-prone regions. The requirement that a building undergo a diaphragm evaluation, involving a significant investigative and analytical effort by an engineer, must be regarded as an extraordinary burden that is only justifiable on the basis of a commensurately extraordinary hazard. Therefore, that burden should be limited to where there is sufficient evidence that a major threat exists. Tying the trigger to hurricane-prone regions limits the provision’s scope to known areas of past vulnerability that are threatened by extraordinary winds.

How the proposal solves it, in concept, and a point by point explanation and rationale for each proposed change: Increases the triggering wind speed to greater than 130 mph, a value that is commensurate with the speed above which glazed openings in new buildings must be protected by means of an impact-protective system or impact-resistant glazing. This speed is deemed reasonable because roofs are more likely to sustain significant damage from uplift where they are subjected to significant positive pressures on one side and negative pressures on the other. This speed is also deemed reasonable because prescriptive requirements for wood framed buildings are not permitted where the design wind speed is greater than 130 mph. Removes an onerous requirement for buildings located in areas where design wind speeds are only moderately greater than 115 mph, and limits the requirements of this section to hurricane-prone regions where there is a history of building failures and/or damage from diaphragm deficiencies.

Cost Impact: The code change proposal will decrease the cost of construction
Proposal will reduce the number of instances when roof diaphragms require evaluation and/or upgrade.
2018 International Existing Building Code

Add new text as follows:

503.16 Smoke compartments. In Group I-2 occupancies where the alteration is on a story used for sleeping rooms for more than 30 care recipients, the story shall be divided into not less than two compartments by smoke barrier walls in accordance with Section 407.5 of the International Building Code as required for new construction.

Revise as follows:

802.3 Smoke compartments. In Group I-2 occupancies where the work area is on a story used for sleeping rooms for more than 30 patients care recipients, the story shall be divided into not less than two compartments by smoke barrier walls in accordance with Section 407.5 of the International Building Code as required for new construction.

Reason:
The purpose of this proposal is to provide coordination between the prescriptive method and the work area method for smoke compartments. This is also consistent with the IFC and is required for hospital licensure.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a licensure requirement for hospitals and nursing homes.
2018 International Existing Building Code

Revise as follows:

503.16 Refuge areas. Where alterations affect the configuration of an area utilized as a refuge area, the capacity of the refuge area shall not be reduced below the required capacity of the refuge area for horizontal exits in accordance with Section 1026.4 of the International Building Code. Where the horizontal exit also forms a smoke compartment, the capacity of the refuge area for Group I-1, I-2 and I-3 occupancies and Group B ambulatory care facilities shall not be reduced below that required in Sections 503.16.1 through 503.16.3, 407.5.3, 408.6.2, 420.6.1 and 422.3.2 of the International Building Code as applicable.

Delete without substitution:

503.16.1 Smoke compartments. In Group I-2 and I-3 occupancies, the required capacity of the refuge areas for smoke compartments in accordance with Sections 407.5.1 and 408.6.2 of the International Building Code shall be maintained.

503.16.2 Ambulatory care. In ambulatory care facilities required to be separated by Section 422.2 of the International Building Code, the required capacity of the refuge areas for smoke compartments in accordance with Section 422.3.2 of the International Building Code shall be maintained.

503.16.3 Horizontal exits. The required capacity of the refuge area for horizontal exits in accordance with Section 1026.4 of the International Building Code shall be maintained.

Revise as follows:

805.10 Refuge areas. Where alterations affect the configuration of an area utilized as a refuge area, the capacity of the refuge area shall not be reduced below the required capacity of the refuge area for horizontal exits in accordance with Section 1026.4 of the International Building Code. Where the horizontal exit also forms a smoke compartment, the capacity of the refuge area for Group I-1, I-2 and I-3 occupancies and Group B ambulatory care facilities shall not be reduced below that required in Sections 805.10.1 and 805.10.2, 407.5.3, 408.6.2, 420.6.1 and 422.3.2 of the International Building Code as applicable.

Delete without substitution:

805.10.1 Capacity. The required capacity of refuge areas shall be in accordance with Sections 805.10.1.1 through 805.10.1.3.

805.10.1.1 Group I-2. In Group I-2 occupancies, the required capacity of the refuge areas for smoke compartments in accordance with Section 407.5.1 of the International Building Code shall be maintained.

805.10.1.2 Group I-3. In Group I-3 occupancies, the required capacity of the refuge areas for smoke compartments in accordance with Section 408.6.2 of the International Building Code shall be maintained.

805.10.1.3 Ambulatory care. In ambulatory care facilities required to be separated by Section 422.2 of the International Building Code, the required capacity of the refuge areas for smoke compartments in accordance with Section 422.3.2 of the International Building Code shall be maintained.

805.10.2 Horizontal exits. The required capacity of the refuge area for horizontal exits in accordance with Section 1026.4 of the International Building Code shall be maintained.

Reason:
The purpose is to make refuge area capacity requirements consistent across the codes. The current IEBC text does not include the provisions for Group I-1. In looking to add that, it seems better to take the approach in IBC Section 1026 and just provide references.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This is a coordination item.
2018 International Existing Building Code

SECTION 503
ALTERATIONS

Add new text as follows:

503.17 Group I-2. In Group I-2 occupancies, existing elements within the area undergoing alterations shall comply with Chapter 11 of the International Fire Code.

SECTION 701
GENERAL

Add new text as follows:

701.3 Group I-2. In Group I-2 occupancies, existing elements within the work area shall comply with Chapter 11 of the International Fire Code.

SECTION 702
BUILDING ELEMENTS AND MATERIALS

Add new text as follows:

702.7 Group I-2, Condition 2 location. Existing Group I-2, Condition 2 shall not be located on a floor level higher than the floor level limitation in Table 1105.3 of the International Fire Code based on the type of construction.

SECTION 703
FIRE PROTECTION

Add new text as follows:

703.2 Incidental uses in Group I-2. In Group I-2 occupancies, existing incidental use areas within the work area shall comply with Section 1105.4 of the International Fire Code.

703.3 Corridor construction in Group I-2. In Group I-2 occupancies, existing corridors, including openings, within the work area shall comply with Section 1105.5 of the International Fire Code.

703.4 Waste and linen chutes. In Group I-2 occupancies, existing waste and linen chutes shall comply with Sections 1103.4.9 of the International Fire Code.

SECTION 704
MEANS OF EGRESS

Add new text as follows:

704.2 Means of egress in Group I-2. In Group I-2 occupancies, existing means of egress within the work area shall comply with Sections 1105.1 and 1105.6 of the International Fire Code.

704.3 Group I-2 care suites. Care suites in existing Group I-2, Condition 2 occupancies shall comply with Sections 407.4.4 through 407.4.4.6.2 of the International Building Code.

Revise as follows:

SECTION 802
BUILDING ELEMENTS AND MATERIALS

Add new text as follows:

802.2.2 Group I-2 and I-3 occupancies. In Group I-2 and I-3 occupancies, interior vertical openings connecting two or more stories shall comply with Section 1103.4.1 of the International Fire Code.
802.3 Smoke compartments. In Group I-2 occupancies where the work area is on a story used for sleeping rooms for more than 30 patients, the story shall be divided into not less than two compartments by smoke barrier walls in accordance with Section 407.5 of the International Building Code as required for new construction. Existing smoke barriers shall comply with Section 1105.7.2 through 1105.7.6 of the International Fire Code.

Reason: The Healthcare committee worked over the last several cycles to match the federal requirements for Medicare reimbursement (K-tags) with the IFC requirements for existing buildings. While this is required for most existing hospitals, not everything is caught during survey. A cross check of these basic requirements during the review of alteration projects would be a useful mechanism to increase compliance. Where there are alterations, there is the opportunity to make sure existing elements within the work area comply. Therefore, the requirements for hospitals in IFC Chapter 11 should be referenced in the IEBC.

The scope of this committee is limited to healthcare, so this proposal does not bring in requirements for uses other than that that are addressed in the IFC Chapter 11.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

These requirements are bare minimum standards for all existing buildings and would be a requirement whether a facility is performing renovations or not.

Proposal # 4260

EB61-19
EB62-19

IEBC®: 503.17 (New), 704.2 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

Add new text as follows:

503.17 Locking arrangements in educational occupancies. In Group E occupancies, Group B educational occupancies and Group I-4 occupancies, egress doors with locking arrangements designed to keep intruders from entering the room shall comply with Section 1010.1.4.4 of the International Building Code.

704.2 Locking arrangements in educational occupancies. In Group E occupancies, Group B educational occupancies and Group I-4 occupancies, egress doors with locking arrangements designed to keep intruders from entering the room shall comply with Section 1010.1.4.4 of the International Building Code.

Reason: This proposal is intended to correlate with provisions found with the IBC and IFC and provide the necessary tools so that additional security can be provided for lockdowns without compromising the safety of occupants by delaying egress and rescue by first responders. Code Change proposal E48-18 was recently approved as submitted by the Means of Egress committee and revises the IBC and IFC. This proposal provides consistency on this issue within the I-Codes. Note that this concept was introduced into the IEBC as Proposal EB23-15 and was initially approved as modified but was ultimately disapproved during OGCV. This gap needs to be addressed and this will be consistent with the IFC and IBC. The following text is the approved language to the 2018 IBC and IFC that will be within the 2021 I-Codes (E48-18 AS).

2021 International Building Code and International Fire Code

1010.1.4.4 Locking arrangements in educational occupancies. In Group E occupancies, Group B educational occupancies and Group I-4 occupancies, egress doors from classrooms, offices and other occupied rooms with locking arrangements designed to keep intruders from entering the room shall comply with all of the following conditions:

1. The door shall be capable of being unlocked from outside the room with a key or other approved means.

2. The door shall be openable from within the room in accordance with Section 1010.1.9.

3. Modifications shall not be made to listed panic hardware, fire door hardware or door closers.

4. Modifications to fire door assemblies shall be in accordance with NFPA 80.

Remote locking or unlocking of doors from an approved location shall be permitted in addition to the unlocking operation in Item 1.

2021 International Fire Code Revise as follows

1031.2.2 Locking arrangements in educational occupancies. In Group E occupancies, Group B educational occupancies and Group I-4 occupancies, egress doors with locking arrangements designed to keep intruders from entering the room shall comply with Section 1010.1.4.4.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a correlation with the requirements that will appear in the 2021 IFC.

Proposal # 4353

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART I WILL BE HEARD THE IEBC COMMITTEE, PART II WILL BE HEARD BY THE IRC-BUILDING COMMITTEE. PLEASE SEE THE TENTATIVE HEARING ORDERS FOR THE RESPECTIVE COMMITTEES.

2018 International Existing Building Code
Revise as follows:

5 PRESCRIPTIVE COMPLIANCE METHOD

SECTION 505
WINDOWS AND EMERGENCY ESCAPE OPENINGS

505.1 Replacement glass. The installation or replacement of glass shall be as required for new installations.

505.2 Replacement window Window opening control devices on replacement windows. In Group R-2 or R-3 buildings containing dwelling units, and one- and two-family dwellings and townhouses regulated by the International Residential Code, window opening control devices or fall prevention devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. One of the following applies:
   3.1. In Group R-2 or R-3 buildings containing dwelling units, the top bottom of the sill clear opening of the window opening is at a height less than 36 inches (915 mm) above the finished floor.
   3.2. In one- and two-family dwellings and townhouses regulated by the International Residential Code, the top bottom of the sill clear opening of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
4. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere when the window is in its largest opened position.
5. The vertical distance from the top bottom of the sill clear opening of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1030.2 of the International Building Code.

Exceptions: Exception:

4. Operable windows where the top bottom of the sill clear opening of the window opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2006.

505.3 Replacement window for emergency escape and rescue openings. Where windows are required to provide emergency escape and rescue openings in Group R-2 and R-3 occupancies and one- and two-family dwellings and townhouses regulated by the International Residential Code, replacement windows shall be exempt from the requirements of Sections 1030.2, 1030.3 and 1030.4 of the International Building Code and Sections R310.2.1, R310.2.2 and R310.2.3 R310.2 and R310.4 of the International Residential Code, provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
2. The replacement of the window is not part of a change of occupancy it shall comply with Section 1011.4.6. Window opening control devices complying with ASTM F2090 shall be permitted for use on windows required to provide emergency escape and rescue openings.
Add new text as follows:

505.3.1 Control devices. Emergency escape and rescue openings with window opening control devices or fall prevention devices complying with ASTM F2090, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools.

Revise as follows:

505.4 Emergency escape and rescue openings. Bars, grilles, covers or screens. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, covers, grates, screens or similar devices are permitted to be placed over emergency escape and rescue openings provided that the bulkhead enclosure or window wells that serve such openings, provided all of the following conditions are met:

1. The minimum net clear opening size complies with the code that was in effect at the time of construction and such
2. Such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening.
3. Where such bars, grilles, grates or similar devices are installed, they shall not reduce the net clear opening of the emergency escape and rescue openings.
4. Smoke alarms shall be installed in accordance with Section 907.2.10 of the International Building Code regardless of the valuation of the alteration.

SECTION 702
BUILDING ELEMENTS AND MATERIALS

702.4 Window opening control devices on replacement windows. In Group R-2 or R-3 buildings containing dwelling units and one- and two-family dwellings and townhouses regulated by the International Residential Code, window opening control devices or fall prevention devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. One of the following applies:
   3.1. In Group R-2 or R-3 buildings containing dwelling units, the top bottom of the clear opening of the window opening is at a height less than 36 inches (915 mm) above the finished floor.
   3.2. In one- and two-family dwellings and townhouses regulated by the International Residential Code, the top bottom of the clear opening of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
4. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere when the window is in its largest opened position.
5. The vertical distance from the top bottom of the clear opening of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm)-

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1030.2 of the International Building Code.

Exceptions: Exception:

1. Operable windows where the top bottom of the clear opening of the window opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

702.5 Replacement window for emergency escape and rescue openings. Where windows are required to provide emergency escape and rescue openings in Group R-2 and R-3 occupancies and one- and two-family dwellings and townhouses regulated by the International Residential Code, replacement windows shall be exempt from the requirements of Sections 1030.2, 1030.3, 1030.4 of the International Building Code and Sections R310.2.1, R310.2.2 and R310.2.3 of R310.2 and R310.4 of the International Residential Code, provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening.
2. Where the replacement window is not part of a change of occupancy it shall comply with Section 1011.4.6.
Add new text as follows:

**702.5.1 Control devices.** Emergency escape and rescue openings with Window opening control devices or fall prevention devices complying with ASTM F2090, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools.

Revise as follows:

**701.4 702.6 Emergency escape and rescue openings. Bars, grilles, covers or screens.** Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates, covers, screens or similar devices are permitted to be placed over emergency escape and rescue openings, shall comply with the bulkhead enclosure or window wells that serve such openings, provided all of the following conditions are met:

1. The minimum net clear opening size required by complies with the code that was in effect at the time of construction.
2. Such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening.
3. Where such bars, grilles, grates or similar devices are installed, they shall not reduce the net clear opening of the emergency escape and rescue openings.
4. Smoke alarms shall be installed in accordance with Section 907.2.10 of the International Building Code regardless of the valuation of the alteration.

Proposal # 4157
EB63-19 Part II
IRC®: R310.6 (New), R310.2.5 (New), SECTION AJ102 (New), AJ102.4 (New), AJ102.4.3 (New), AJ102.4.3.1 (New), AJ102.4.4 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Residential Code

Revised as follows:

R310.6 Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing basements undergo alterations or repairs.

Exception: New sleeping rooms created in an existing basement shall be provided with emergency escape and rescue openings in accordance with Section R310.1.

R310.2.5 R310.7 Replacement windows. Windows for emergency escape and rescue openings. Replacement windows installed in buildings meeting the scope of this code shall be exempt from the maximum sill height requirements of Section R310.2.2 and the requirements of Sections R310.2.1 and R310.4, provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window is of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
2. The replacement window is not part of a change of occupancy.

SECTION AJ102 COMPLIANCE

AJ102.4 Replacement windows. Regardless of the category of work, where an existing window, including the sash and glazed portion, or safety glazing is replaced, the replacement window or safety glazing shall comply with the requirements of Sections AJ102.4.1 through AJ102.4.4, as applicable.

AJ102.4.3 Emergency Replacement windows for emergency escape and rescue openings. Where windows are required to provide emergency escape and rescue openings, replacement windows shall be exempt from the maximum sill height requirements of Section R310.2.2 and the requirements of Sections R310.2.1 and R310.2.3 provided Sections R310.2 and R310.4 provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
2. The replacement window is not part of a change of occupancy.

AJ102.4.3.1 Control devices. Emergency escape and rescue openings with window opening control devices or fall prevention devices complying with ASTM F2090, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools.

Revised as follows:

AJ102.4.4 Window control devices. Where window opening control devices or fall prevention devices complying with ASTM F2090 are not provided, window opening control devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. The top of the sill of the clear opening of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
4. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere where the window is in its largest opened position.
5. The vertical distance from the top of the sill of the clear opening of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit.
Reason: The intent of this proposal is coordination with the requirements in existing buildings for the following:

- Replacement windows with opening control devices or fall prevention devices
- Replacement window emergency escape and rescue openings (EEROs)
- Replacement windows that have to comply with both
- Bars and grills over area wells

The main intent of this proposal is to coordinate criteria in the IEBC and IRC. Part of this will be to separate the requirements into distinct sections. They are now mixed. It is not the intent to add items where they are not currently required. IRC appendix J does not address Item 4 and IRC Section 319 does not address Item 1, 3 or 4.

Item 1

IEBC Section 404.2 and 702.4, IRC AJ102.3.3 - F2020 includes provisions for opening control devices and fall prevention devices. By putting this in the main text, Exception 2 is not needed. (Since the IRC only deals with buildings 3 stories or less, it does not need the exception for devices permitted in taller buildings.) The term "bottom of the clear opening" is easier to determine and measure than "top of sill". This term is consistent with the proposals for new windows. The information under Item 5 has been relocated to the section dealing with Item 3.

Item 2

IEBC Section 505.3, 702.5, and IRC AJ102.4.3 and R310.7 - The changes in the references have to technical change. They match the package for IBC and IRC EERO requirements. The language dealing with control devices has been relocated to the section dealing with Item 3.

Item 3

IEBC Section 505.3.1, 702.5.1 and IRC Section AJ102.4.3.1 - This section includes the criteria for opening control devices and fall prevention devices on EEROs.

Item 4

IEBC 505.4 and 702.6. - The revisions are consistent in what was approved for IBC Section 1030.5 and IRC Section 310.4 in the 2018 codes. Section 701.4 should be relocated to the window provisions. That would be consistent with the organization for EEROs in IBC and IRC and the IEBC prescriptive method.

This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is a correlation item between codes.

Proposal # 5754

EB63-19 Part II
EB64-19

IEBC®: 505.1

Proponent: Timothy Pate, Colorado Chapter Code Change Committee, representing City and County of Broomfield (tpate@broomfield.org)

2018 International Existing Building Code

Revise as follows:

505.1 Replacement glass windows. The installation or replacement of glass windows shall be as required for new installations.

Reason: This proposal is to change this section to deal with replacement windows and not glass. First of all replacing glass should be considered a repair and not an alteration so this requirement is not even in the correct chapter. Also it does not make sense to have a requirement in this code since that would appear to require a permit for anytime someone needs to replace a broken window. Consider the amount of new permits a jurisdiction would need to do on a daily basis. It does make sense to change the language to deal with replacement of windows which would be the entire assembly. Most jurisdictions to require permits for these window changeouts in order to make sure both energy code and life safety code are met. Finally I would point out that the 2018 IECC sections C504.2 and R504.2 have an exception to not require glass only replacements in existing sash and frames to meet current energy code and by default not require permits.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This will not increase or decrease cost of construction but will decrease cost of getting permits which will save money for the jurisdictions

Proposal # 4522
EB65-19

IEBC®: 505.2

Proponent: Jeff Inks, representing Window and Door Manufacturers Association (jinks@wdma.com); Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@jhatfieldandassociates.com)

2018 International Existing Building Code

Revise as follows:

505.2 Replacement window opening control devices. In Group R-2 or R-3 buildings containing dwelling units, and one- and two-family dwellings and townhouses regulated by the International Residential Code, window opening control devices complying with ASTM F2090 shall be installed where an existing window, including the sash and glazed portion, is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. One of the following applies:
   2.1. In Group R-2 or R-3 buildings containing dwelling units, the top of the sill of the window opening is at a height less than 36 inches (915 mm) above the finished floor.
   2.2. In one- and two-family dwellings and townhouses regulated by the International Residential Code, the top of the sill of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
3. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere when the window is in its largest opened position.
4. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1030.2 of the International Building Code.

Exceptions:

1. Operable windows where the top of the sill of the window opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

Reason: This revision makes it clear that regardless of whether replacing the entire existing window (sash and frame), or the sash and glazed portion with an insert window where the existing frame remains, the window fall prevention requirements apply in both applications which is consistent with how the code treats these replacements for energy efficiency.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The intent of this proposal is to ensure window fall prevention requirements are met as intended by the code. It does not have a direct impact on cost.
EB66-19

IEBC®: 506.4.2, [BS] 1006.2

Proponent: Terry Kozlowski, representing Southern Nevada Chapter; Valarie Evans, representing Southern Nevada Chapter; Amanda Moss, representing SN-ICC Member; Cassidy Wilson, representing SN-ICC Member; Nenad Mirkovic, representing City of Las Vegas (nmirkovic@lasvegasnevada.gov)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

506.4.2 Snow and wind loads. Where a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608 and 1609 of the International Building Code for the new risk category.

Exception:

1. Where the area of the new occupancy is less than 10 percent of the building area, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.
2. Change of occupancy to Group A with an occupant load less than 500 in an existing one-story building.

[BS] 1006.2 Snow and wind loads. Where a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608 and 1609 of the International Building Code for the new risk category.

Exception:

1. Where the area of the new occupancy is less than 10 percent of the building area. The cumulative effect of occupancy changes over time shall be considered.
2. Change of occupancy to Group A with an occupant load less than 500 in an existing one-story building.

Reason: More than 12,000 stores in 2018 and 50% of the 1,200 shopping malls across the U.S. are expected to close by 2023. This alarming trend will impact future redevelopment efforts in these existing structures. This proposal will promote the redevelopment efforts of municipalities, by reducing the construction cost without compromising security and safety of the occupants.

This proposal does not adversely impact any of the architectural and/or fire design requirements. This proposal will increase the threshold from 300 to 500 occupants.

The 300 occupant load threshold may be based on the 1942 Boston fire (Exhibit D) due to the number of fatalities. Fire sprinkler, fire alarm, interior finish and structural design provisions in the code provide more protection in today’s structures.

We looked to the life safety egress provisions where 500 is the threshold for when a 3rd exit is required as a good point to upgrade the structural threshold. 500 is also consistent with the current Risk Category III threshold for post 12th grade educational occupancies.

Exhibit A states the IBC and/or IEBC: “is a model code that provides minimum requirements to safeguard the public health, safety and general welfare of the occupants of new and existing buildings and structures…”

When reviewing a list of notable earthquakes and fatalities associated with events from January 26, 1700 to January 23, 2018 (318 years), there have been approximately 3,919 fatalities (Exhibit A). In comparison, Exhibit B shows motor vehicle deaths in the U.S. for the last 11 years. In 2017 alone, there were 37,133 vehicle deaths. Exhibit C (2007-2016) show there were 145 fire-related fatalities and 1,550 injuries in non-residential fires. These statistics provide comparison in historical data as to the number of deaths in structures during earthquakes.

Bibliography:
1. 1927 UBC (occupancy Group C-1) it is seating capacity in any one room of less than 500 (Exhibit “E”);
2. 1943 UBC (occupancy Group B-2) it is seating capacity in any one room of 100 or more (Exhibit “E”);
3. November 1942 Boston Night Club Fire (see LA Times form 11/29/1942, Exhibit “D”) It should be noted that the 1943 UBC was approved for printing on 10/1942, prior to the fire);
4. 1946 UBC, occupancy Group B-2 with seating capacity in any one room of 300 or more and occupancy Group B-3 with seating capacity in any one room of less than 300 (Exhibit “E”);
5. 1949 IBC occupancy Group B-2 with an occupant load in in the building of 300 or more and occupancy Group B-3 with an occupant load in the building of less than 300 (Exhibit “E”).
Cost Impact: The code change proposal will decrease the cost of construction
This proposal will decrease the cost of construction for structures with an occupant load of less than 500 by eliminating the requirement of seismic analysis and potential additional costs associated with improvements to existing structures.
EB67-19

IEBC®: 506.4.3, [BS]1006.3

Proponent: Terry Kozlowski, representing Southern Nevada Chapter; Valarie Evans, representing Southern Nevada Chapter; Amanda Moss, representing SN-ICC Member; Cassidy Wilson, representing SN-ICC Member; Nenad Mirkovic, representing City of Las Vegas (nmirkovic@lasvegasnevada.gov)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

506.4.3 Seismic loads (seismic force-resisting system). Where a change of occupancy results in a building being assigned to a higher risk category, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where the area of the new occupancy is less than 10 percent of the building area and the new occupancy is not assigned to Risk Category IV, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.
2. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B, shall be permitted to use Appendix Chapter A1 of this code.
4. Change of occupancy to Group A with an occupant load not to exceed 500 in an existing one-story building.

[BS]1006.3 Seismic loads. Where a change of occupancy results in a building being assigned to a higher risk category, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33.
2. Where the area of the new occupancy is less than 10 percent of the building area and the new occupancy is not assigned to Risk Category IV. The cumulative effect of occupancy changes over time shall be considered.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B shall be permitted to use Appendix Chapter A1 of this code.
4. Change of occupancy to Group A with an occupant load not to exceed 500 in an existing one-story building.

Reason: More than 12,000 stores in 2018 and 50% of the 1,200 shopping malls across the U.S. are expected to close by 2023. This alarming trend will impact future redevelopment efforts in these existing structures. This proposal will promote the redevelopment efforts of municipalities, by reducing the construction cost without compromising security and safety of the occupants.

This proposal does not adversely impact any of the architectural and/or fire design requirements. This proposal will increase the threshold from 300 to 500 occupants.

The 300 occupant load threshold may be based on the 1942 Boston fire (Exhibit D) due to the number of fatalities. Fire sprinkler, fire alarm, interior finish and structural design provisions in the code provide more protection in today’s structures.

We looked to the life safety egress provisions where 500 is the threshold for when a 3rd exit is required as a good point to upgrade the structural threshold. 500 is also consistent with the current Risk Category III threshold for post 12th grade educational occupancies.

Exhibit A states the IBC and/or IEBC: “is a model code that provides minimum requirements to safeguard the public health, safety and general welfare of the occupants of new and existing buildings and structures…”

When reviewing a list of notable earthquakes and fatalities associated with events from January 26, 1700 to January 23, 2018 (318 years), there have been approximately 3,919 fatalities (Exhibit A). In comparison, Exhibit B shows motor vehicle deaths in the U.S. for the last 11 years. In 2017 alone, there were 37,133 vehicle deaths. Exhibit C (2007-2016) show there were 145 fire-related fatalities and 1,550 injuries in non-residential fires.

These statistics provide comparison in historical data as to the number of deaths in structures during earthquakes.

Bibliography: 1. 1927 UBC (occupancy Group C-1) it is seating capacity in any one room of less than 500 (Exhibit “E”);
2. 1943 UBC (occupancy Group B-2) it is seating capacity in any one room of 100 or more (Exhibit “E”);

3. November 1942 Boston Night Club Fire (see LA Times form 11/29/1942, Exhibit “D”) It should be noted that the 1943 UBC was approved for printing on 10/1942, prior to the fire);

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

SECTIO
506
CHANGE OF OCCUPANCY

Revise as follows:

506.4.3 Seismic loads (seismic force-resisting system). Where a change of occupancy results in a building being assigned to a higher risk category, or where the change is from a Group S or Group U occupancy to any occupancy other than Group S or Group U, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where the area of the new occupancy is less than 10 percent of the building area, the occupant load of the area with the new occupancy is not increased, and the new occupancy is not assigned to Risk Category IV, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.
2. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B, shall be permitted to use Appendix Chapter A1 of this code.
4. Where the change is from a Group S or Group U occupancy, use of reduced seismic forces shall be permitted.

SECTION 1006
STRUCTURAL

[BS]1006.3 Seismic loads. Where a change of occupancy results in a building being assigned to a higher risk category, or where the change is from a Group S or Group U occupancy to any occupancy other than Group S or Group U, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required.
2. Where the area of the new occupancy is less than 10 percent of the building area, the occupant load of the area with the new occupancy is not increased, and the new occupancy is not assigned to Risk Category IV. The cumulative effect of occupancy changes over time shall be considered.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B shall be permitted to use Appendix Chapter A1 of this code.
4. Where the change is from a Group S or Group U occupancy, use of reduced seismic forces shall be permitted.

Reason: Quite often, storage, parking, or utility areas, often unfinished, are converted to occupied residential units or leasable office or commercial space. In a seismically deficient building, such a change represents a significant increase in risk that the code should not ignore. The current proposal revises the change of occupancy trigger, by re-introducing seismic upgrade triggers of the type the code had until 2012 to specifically address conversion from unoccupied space (U and S occupancies) to commercial and residential space (B and R occupancies), but with the allowance of reduced loads. Matching provisions are proposed for the Prescriptive (IEBC Section 506) and Work Area (IEBC Section 1006) methods.

In the 2012 IBC and IEBC, the seismic upgrade triggers for change of occupancy projects were greatly simplified so that an upgrade is triggered only when the change is so significant that it elevates the building into a higher risk category. This was a useful improvement to the previous set of triggers, but it was an over-reach in one regard: Quite often, the ground floor of a residential building is converted from a storage, parking, or utility area, often unfinished, to an occupied residential unit or leasable office or commercial space. Similarly, warehouses are often converted to residences and offices. In a seismically deficient building, the related increase in the number of (actual) occupants represents a significant increase in risk that the code should not ignore.
In the 2009 IEBC (Work Area method), such a change of occupancy would have triggered a full-building seismic upgrade with full code-level loads. Since 2012, however, since such a change would not affect the risk category (it would be II before and after), no evaluation or upgrade is triggered for these cases.

The alteration normally associated with such a change of occupancy also is unlikely to trigger any seismic work.

This proposal re-introduces the seismic upgrade trigger for these specific cases:

- The proposal restores a requirement that was already in the code in 2009 but was removed in 2012. So there is precedent for what this proposal accomplishes.
- Matching provisions are proposed for the Prescriptive (IEBC Section 506) and Work Area (IEBC Section 1006) methods.
- The 10% “small area” exception is modified to prevent gaming, since the cases in question can involve only part of a story.
- An exception to the full-code criteria is added. Since these occupancy changes are less significant than a wholesale shift in risk category, we suggest that the use of reduced seismic loads is appropriate. For many tilt-up warehouses and wood frame apartment buildings, the use of reduced loads allows use of IEBC Appendix Chapters A2 and A4, which will limit the extent of retrofit work, making the triggered retrofit quite feasible.

**Cost Impact:** The code change proposal will increase the cost of construction

The cost of converting an unfinished space with rare or incidental human occupancy to occupied space would be increased by the cost of a retrofit with reduced forces.

Proposal # 5255
EB69-19
IEBC®: 506.4.3, [BS]1006.3

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

506.4.3 Seismic loads (seismic force-resisting system). Where a change of occupancy results in a building being assigned to a higher risk category, or where the change is from a Group S or Group U occupancy to any occupancy other than Group S or Group U, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where the area of the new occupancy is less than 10 percent of the building area, the occupancy is not changing from a Group S or Group U occupancy, and the new occupancy is not assigned to Risk Category IV, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.

2. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required.

3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B, shall be permitted to use Appendix Chapter A1 of this code.

4. Where the change is from a Group S or Group U occupancy and there is no change of risk category, use of reduced seismic forces shall be permitted.

[BS]1006.3 Seismic loads. Where a change of occupancy results in a building being assigned to a higher risk category, or where the change is from a Group S or Group U occupancy to any occupancy other than Group S or Group U, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.

2. Where the area of the new occupancy is less than 10 percent of the building area, the occupancy is not changing from a Group S or Group U occupancy, and the new occupancy is not assigned to Risk Category IV, compliance with this section is not required.

3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B shall be permitted to use Appendix Chapter A1 of this code.

4. Where the change is from a Group S or Group U occupancy and there is no change of risk category, use of reduced seismic forces shall be permitted.

Reason: This proposal re-introduces a common sense seismic upgrade trigger of the type the code had until 2012. To make the trigger more feasible, it allows reduced loads.

Since the 2012 IEBC, a change of occupancy project triggers seismic upgrade only when the change is so significant that it bumps the building into a higher risk category. While this is preferable to the pre-2012 triggers (which were arbitrary and needlessly complex), it misses the common case in which an unoccupied storage, parking, or utility area is converted to an occupied residential unit or leasable office or commercial space. In a seismically deficient building, such a change amounts to adding units to substandard buildings -- and often in the ground story where potential collapse poses the greatest safety risk. This is just as risky as building new housing to grossly obsolete seismic standards. The growing interest in accessory dwelling units (ADUs) makes the risk even more urgent. Converting collapse-prone unoccupied space to new occupied space represents a significant increase in risk that the code should not ignore.

However, since Group S, U, R, B, and M occupancies are all typically assigned to Risk Category II, a change from S or U to R, B, or M would not trigger any seismic work by the current code. In the 2009 IEBC (Work Area method), such a change would have triggered a full-building seismic upgrade with full code-level loads.

This proposal would re-introduce the seismic upgrade trigger for these specific cases. It makes identical changes to both the Prescriptive and Work Area methods.

The proposal has precedent, since a similar requirement was already in the 2009 IEBC.
The 10% "small area" exception is modified appropriately, to make sure that a change from S or U to occupied space would not escape review just because it is only in the first story of a large building.

Reduced forces are allowed. Since these occupancy changes are less significant than a whole-building shift in risk category, the use of reduced seismic loads is appropriate. (Some might argue that adding units to a building that meets only reduced seismic criteria is still an increase in risk relative to new construction. That is true, but the growth of ADU programs calls for the feasibility afforded by reduced loads. This proposal is meant to facilitate ADU programs, but not for grossly deficient buildings that reduced seismic criteria would catch. For many woodframe apartment buildings, the use of reduced loads also allows IEBC Appendix A4, which would effectively limit any retrofit work to the first story, making the triggered retrofit quite feasible.)

**Cost Impact:** The code change proposal will increase the cost of construction
The cost of converting an unfinished space to a functional residential unit would be increased by the cost of a retrofit with reduced forces.
IEBC®: 603.1

Proponent: Allison Cook, representing VBCOA; David Collins, representing The American Institute of Architects (dcollins@preview-group.com); Debra McMahon (debra.mcmahon@fairfaxcounty.gov); Kenney Payne, Moseley Architects, representing AIA Virginia (kpayne@moseleyarchitects.com); Ronald Clements Jr., representing Chesterfield County (clementsro@chesterfield.gov); Shaina Abney, representing VBCOA (shaina.abney@fairfaxcounty.gov); Bob Orr, Culpeper County, representing VBCOA (borr@culpepercounty.gov); Charles Vernon, representing VBCOA (cvern@arlingtonva.us); Michael Williams (mike.williams@harrisonburgva.gov); Christina Jackson, representing City of Norfolk / WICED of VA (christina.reynolds@norfolk.gov)

2018 International Existing Building Code

Revise as follows:

603.1 Scope. Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment; and shall apply where the work area is equal to or less than 50 percent of the building area.

Reason: The use of "work area", which is a defined term, instead of "reconfigured spaces" provides clarification and consistency by using defined terms. The addition of "50% or less" is to align with the scope of a level 3, which applies when the work area that exceeds 50%

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal is only to clarify the language.

Proposal # 5225
EB71-19

IEBC: [A] 105.2, 603.1, 704.2 (New), 801.3 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

[A] 105.2 Work exempt from permit. Exemptions from permit requirements of this code shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other laws or ordinances of this jurisdiction. Permits shall not be required for the following:

Building:

1. Sidewalks and driveways not more than 30 inches (762 mm) above grade and not over any basement or story below and that are not part of an accessible route.
2. Painting, papering, tiling, carpeting, cabinets, counter tops, and similar finish work.
3. Temporary motion picture, television, and theater stage sets and scenery.
4. Shade cloth structures constructed for nursery or agricultural purposes, and not including service systems.
5. Window awnings supported by an exterior wall of Group R-3 or Group U occupancies.
6. Movable cases, counters, and partitions not over 5 feet 9 inches (1753 mm) in height.

Electrical:

1. Repairs and maintenance: Minor repair work, including the replacement of lamps or the connection of approved portable electrical equipment to approved permanently installed receptacles.
2. Radio and television transmitting stations: The provisions of this code shall not apply to electrical equipment used for radio and television transmissions, but do apply to equipment and wiring for power supply, the installations of towers, and antennas.
3. Temporary testing systems: A permit shall not be required for the installation of any temporary system required for the testing or servicing of electrical equipment or apparatus.

Gas:

1. Portable heating appliance.
2. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.

Mechanical:

1. Portable heating appliance.
2. Portable ventilation equipment.
3. Portable cooling unit.
4. Steam, hot, or chilled water piping within any heating or cooling equipment regulated by this code.
5. Replacement of any part that does not alter its approval or make it unsafe.
6. Portable evaporative cooler.
7. Self-contained refrigeration system containing 10 pounds (4.54 kg) or less of refrigerant and actuated by motors of 1 horsepower (746 W) or less.

Plumbing:

1. The stopping of leaks in drains, water, soil, waste, or vent pipe; provided, however, that if any concealed trap, drainpipe, water, soil, waste, or vent pipe becomes defective and it becomes necessary to remove and replace the same with new material, such work shall be considered as new work, and a permit shall be obtained and inspection made as provided in this code.
2. The clearing of stoppages or the repairing of leaks in pipes, valves, or fixtures, and the removal and reinstallation of water closets, provided that such repairs do not involve or require the replacement or rearrangement of valves, pipes, or fixtures.

603.1 Scope. Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.

Exception: The movement or addition of non-fixed and movable fixtures, cases, racks, counters and partitions not over 5 feet 9 inches (1753mm) in height shall not be considered a Level 2 alteration.

SECTION 704
MEANS OF EGRESS

704.1 General. Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Add new text as follows:

704.2 Casework. Addition, alteration or reconfiguration of non-fixed and movable cases, counters, and partitions not over 5 feet 9 inches (1753 mm) in height shall maintain the required means of egress path.

801.3 System installations. Requirements related to work area are not applicable where the Level 2 alteration alterations are limited solely to one or more of the following:

1. Mechanical systems, electrical systems, fire protection systems and abatement of hazardous materials.
2. Windows, hardware, operating controls, electrical outlets and signs.
3. Alterations undertaken for the primary purpose of increasing the accessibility of a facility.

Reason: There are many issues of confusion in determining what is considered a “work area.” The definition of “work area” specifically states “reconfiguration of space.” It should address when the floor plan (egress etc.) changes not when a sprinkler system is installed in a building. Also what is included in reconfiguration – furniture/cubicles? Part of the confusion with this issue is that there seems to be a need to establish a work area where in some cases none exist. It can still be a level 2 alteration but with no work area associated with it. This does not mean that there are no regulations just that it will not necessarily make some provisions applicable such as those related to egress or move it into a Level 3 alteration situation.
Level 2, as defined in Chapter 6, includes extension of any system. The intent of this proposal is to not throw a project into Level 2 if there is only the movement of casework. The new language in Section 603.1 is to clarify that the movement of casework is not considered reconfiguration of a space and thus moving furniture will not be considered a Level 2 alteration. The addition to Section 704.2 is due to a concern that the movement of casework should not violate allowances for means of egress. Since these elements are exempt from permits (but not code requirements), the change to Section 105.2 is just for consistent terminology.

Section 801.3: If an alteration does not change the physical configuration of a space or is to improve accessibility, this should also not throw a building owner into an additional series of requirements. This allows for building owners to improve their buildings over time.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will decrease the cost of construction
This would allow improvements that did not change the configuration of the space to not trigger Level 2 or 3 requirements.
Delete without substitution:

**SECTION 608 - RELOCATED BUILDINGS**

608.1 Scope. Relocated building provisions shall apply to relocated or moved buildings.

608.2 Application. Relocated buildings shall comply with the provisions of Chapter 14.

Reason: Section 301.4 already denotes that outside the three methods that relocated buildings are addressed by Chapter 14.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Editorial change.
Proponent: Jeff Inks, representing Window and Door Manufacturers Association (jinks@wdma.com); Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@hatfieldandassociates.com)

2018 International Existing Building Code

Revise as follows:

702.4 Window opening control devices on replacement windows. In Group R-2 or R-3 buildings containing dwelling units and one- and two-family dwellings and townhouses regulated by the International Residential Code, window opening control devices complying with ASTM F2090 shall be installed where an existing window, including the sash and glazed portion, is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. One of the following applies:
   3.1. In Group R-2 or R-3 buildings containing dwelling units, the top of the sill of the window opening is at a height less than 36 inches (915 mm) above the finished floor.
   3.2. In one- and two-family dwellings and townhouses regulated by the International Residential Code, the top sill of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
4. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere when the window is in its largest opened position.
5. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1030.2 of the International Building Code.

Exceptions:

1. Operable windows where the top of the sill of the window opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

Reason: This revision makes it clear that regardless of whether replacing the entire existing window (sash and frame), or the sash and glazed portion with an insert window where the existing frame remains, the window fall prevention requirements apply in both applications which is consistent with how the code treats these replacements for energy efficiency.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The intent of this proposal is to ensure window fall prevention requirements are met as intended by the code. It does not have a direct impact on cost.
2018 International Existing Building Code

SECTION 704
MEANS OF EGRESS

704.1 General. Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Add new text as follows:

704.1.1 Projections in Nursing Home Corridors. In Group I-2, Condition 1 occupancies, where the corridor is at least 96 inches wide, projections into the corridor width are permitted in accordance with Section 407.4.3 of the International Building Code.

SECTION 805
MEANS OF EGRESS

805.1 Scope. The requirements of this section shall be limited to work areas that include exits or corridors shared by more than one tenant within the work area in which Level 2 alterations are being performed, and where specified they shall apply throughout the floor on which the work areas are located or otherwise beyond the work area.

805.2 General. The means of egress shall comply with the requirements of this section.

Exceptions:

1. Where the work area and the means of egress serving it complies with NFPA 101.
2. Means of egress complying with the requirements of the building code under which the building was constructed shall be considered to be compliant means of egress if, in the opinion of the code official, they do not constitute a distinct hazard to life.

Add new text as follows:

805.3 Group I-2. In Group I-2 occupancies, in areas where corridors are used for movement of care recipients in beds, the clear width of ramps and corridors shall be not less than 48 inches (1219 mm).

Reason: The purpose of this proposal is to address required corridor width in Group I-2. The change to Level 1 alterations is to allow for furniture to be added into the corridors in nursing homes. This is currently allowed in the IBC so that seating areas for socialization and to allow for residents to sit down to rest are permitted where the furniture will not block the means of egress.

The change to Level 2 alterations is to allow for existing corridors to remain at the 48” width as permitted in the IFC. It does not make sense to have to make a portion of a corridor wider than the routes leading to and from that portion.

Dead ends are addressed in another proposal to IEB Section 805.6.

The following text is in the IFC.

IFC

1105.6.3 Ramps. In areas where ramps are used for movement of patients in beds, the clear width of the ramp shall be not less than 48 inches (1219 mm).

1105.6.4 Corridor width. In areas where corridors are used for movement of patients in beds, the clear width of the corridor shall be not less than 48 inches (1219 mm).

1105.6.5 Dead-end corridors. In smoke compartments containing patient sleeping rooms and treatment rooms, dead-end corridors shall not exceed 30 feet (9144 mm) unless approved by the fire code official.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and
debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This change would allow for additional design options.
EB75-19
IEBC®: [BS] 705.2; IBC®: 1511.2

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 705.2 1501.2.1 Structural and construction loads. Structural roof components shall be capable of supporting the roof-covering system and the material and equipment loads that will be encountered during installation of the system.

2018 International Building Code

4614.2 3301.2.1 Structural and construction loads. Structural roof components shall be capable of supporting the roof-covering system and the material and equipment loads that will be encountered during installation of the system.

Reason: The proposal moves a provision about construction loads from IEBC Chapter 7 (Alterations – Level 1) to Chapter 15 (Construction Safeguards). Per ICC staff, IEBC Section 705 is linked to IBC Section 1511, so at ICC request, the proposal makes a matching move within the IBC. The motivation for this proposal is simply to make the structural provisions of the IEBC Work Area and Prescriptive methods match as closely as possible – a motivation that received broad support in the last cycle, resulting in greatly improved consistency in the 2018 code.

This provision for reroofing, however, remains out of sync. Currently, the Work Area method has this provision in Section 705.2, but the Prescriptive method has no matching provision.

In the last cycle, proposal EB19-16 would have added a matching provision to the Prescriptive method. The ICC Committee supported the concept but suggested that instead of adding a duplicate provision, Section 705.2 should be moved to Chapter 15 where it made more sense and could serve both methods. Therefore, following the committee’s suggestion, a public comment was submitted. At the PCH, the comment was easily approved by a nearly unanimous show of hands, but it received only 65% approval by OGV voters, so EB19-16 As Modified could not be approved despite broad consensus.

(Note: While both parts of this proposal should be approved, it is perhaps worth noting that the IEBC Prescriptive method still lacks reroofing provisions to match those of the Work Area method in Sec 705. To resolve this, one might propose creating a new section in IEBC Chapter 5 to match the remaining provisions in Sec 705. That could be done as a floor modification or as a public comment, but it is outside the initial narrow scope of this proposal. Going even further, one might propose deleting the rest of IBC Sec 1511 because it is entirely about reroofing, which is an Existing Buildings issue, but that, too, is outside the scope of this proposal.)

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal merely relocates existing provisions to more logical places.
EB76-19

IEBC®: [BS] 706.2, (New)

Proponent: Michael Fillion, representing National Council of Structural Engineers Association (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] 706.2 Addition or replacement of roofing or replacement of equipment. Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is due entirely to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering. This exception shall not apply where insulation is added to the roof assembly.

Add new definition as follows:

[BS] ROOF COVERING. The covering applied to the roof deck for weather resistance, fire classification or appearance.

Reason: In many re-roofing projects, insulation and membrane are placed over an existing roof covering. The weight of the insulation and membrane are usually less than 3 pounds per square foot (0.1437 kN/m²). It has been our observation that some design professionals and building officials are using this exception when insulation is added with the new second layer of roof covering. Addition of insulation increases the thermal resistance (R-value) resulting in a higher Thermal Factor, Ct which will increase the design roof snow load. Because of this oversight in some instances, we feel it is important to include the IBC roof covering definition and to make it clear that adding insulation is not included in Exception #2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The intent of this code change proposal is for clarification.

Proposal # S326

__________________________________________________________

EB76-19
Proponent: Allison Cook, representing VBCOA; Kenney Payne, Moseley Architects, representing AIA Virginia (kpayne@moseleyarchitects.com); Ronald Clements Jr, representing Chesterfield County (clementsro@chesterfield.gov); Bob Orr, representing VBCOA (borr@culpepercounty.gov); Charles Vernon, representing VBCOA (cvernon@arlingtonva.us); Michael Williams (mike.williams@harrisonburgva.gov); Debra McMahon (debra.mcmahon@fairfaxcounty.gov); David Collins, representing The American Institute of Architects (dcollins@preview-group.com); Christina Jackson, representing City of Norfolk / WICED of VA (christina.reynolds@norfolk.gov)

2018 International Existing Building Code

Revise as follows:

707.1 Minimum requirements. Level 1 alterations to existing buildings or structures do not require the entire building or structure to comply with the energy requirements of the International Energy Conservation Code or International Residential Code. The alterations shall conform to the energy requirements of the International Energy Conservation Code or International Residential Code as they relate to new construction only.

Exception: Like materials, assemblies or thicknesses shall be permitted for alterations involving the exterior building thermal envelope, provided no hazard to life, health or property is created. Hazardous materials shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

810.1 Minimum requirements. Level 2 alterations to existing buildings or structures are permitted without requiring the entire building or structure to comply with the energy requirements of the International Energy Conservation Code or International Residential Code. The alterations shall conform to the energy requirements of the International Energy Conservation Code or International Residential Code as they relate to new construction only.

Exception: Like materials, assemblies or thicknesses shall be permitted for alterations involving the exterior building thermal envelope, provided no hazard to life, health or property is created. Hazardous materials shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

907.1 Minimum requirements. Level 3 alterations to existing buildings or structures are permitted without requiring the entire building or structure to comply with the energy requirements of the International Energy Conservation Code or International Residential Code. The alterations shall conform to the energy requirements of the International Energy Conservation Code or International Residential Code as they relate to new construction only.

Exception: Like materials, assemblies or thicknesses shall be permitted for alterations involving the exterior building thermal envelope, provided no hazard to life, health or property is created. Hazardous materials shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

Reason: When replacing insulation in the thermal envelope, the energy requirement demands the affected area be in compliance with the International Energy Conservation Code. This can require the tenant to increase the thickness of the wall or roof framing to satisfy the depth of the insulation for proper installation. This would discourage rehabilitation of many older structures. The purpose of the Existing Building code should be to allow existing buildings to be renovated and occupied while maintaining the level of safety. It should not be to retrofit the tenant space or building to meet today’s code.

Cost Impact: The code change proposal will decrease the cost of construction
This should result in a cost savings since a tenant would no longer have to increase the thickness of the wall or roof framing to satisfy the depth of the insulation for proper installation.

Proposal # 5227
EB78-19
IEBC®: 802.4

Proponent: Tim Earl, representing GBH International (tearl@gbhinternational.com)

2018 International Existing Building Code
Revise as follows:

802.4 Interior finish. The interior finish of walls and ceilings in exits and corridors in any work area shall comply with the requirements of the International Building Code.

Exception: Existing interior finish materials that do not comply with the interior finish requirements of the International Building Code shall be permitted to be treated with an approved fire-retardant coating in accordance with the manufacturer’s instructions to achieve the required rating for fire performance. Compliance with this section shall be demonstrated by testing the fire-retardant coating on the same material and achieving the required performance. Where the same material is not available, testing on a similar material shall be permitted.

Reason: It is important to clarify that, if fire retardant coatings are to be used to achieve improved fire performance, they must have been tested on the actual product (substrate) to which they will be applied. There have been instances of manufacturers applying coatings to a noncombustible surface and running an ASTM E84 test in an attempt to demonstrate compliance. (See figures below). This obviously does not reflect real world performance and is not the intent of the code. This proposal would make the requirement more explicit.
Cost Impact: The code change proposal will increase the cost of construction
This proposal may increase the cost of construction if people have using flame retardant coatings that have not been tested on the material to which they will be applied.
EB79-19

IEBC®: 802.4, 802.4.1

Proponent: Marcelo Hirschler, GBH International, representing GBH International (mmh@gbhint.com)

2018 International Existing Building Code

Revise as follows:

802.4 Interior finish. The interior finish and trim of walls and ceilings in exits and corridors in any work area shall comply with the requirements of the International Building Code.

Exception: Existing interior finish materials that do not comply with the interior finish requirements of the International Building Code shall be permitted to be treated with an approved fire-retardant coating in accordance with the manufacturer’s instructions to achieve the required rating.

802.4.1 Supplemental interior finish requirements. Where the work area on any floor exceeds 50 percent of the floor area, Section 802.4 shall apply to the interior finish and trim in exits and corridors serving the work area throughout the floor.

Exception: Interior finish within tenant spaces that are entirely outside the work area.

Reason: The exception is not really a proper exception: the interior finish still must meet the IBC requirements, but that can be achieved by using a fire-retardant coating. The words “and trim” are added for clarification, since it is most likely the intent of the section anyway. The repeated use of “interior finish” is eliminated as unnecessary. The interior finish requirements are based on fire performance in terms of a flame spread index and a smoke developed index (or on results of a room-corner test such as NFPA 286) and are not a rating.

Cost Impact: The code change proposal will increase the cost of construction. This adds the requirement that trim also meet the fire testing in the IBC.
EB80-19

IEBC®: 803.4.4 (New)

Proponent: Thomas Daly, HSCG, representing HSCG (Thomas.Daly@myhscg.com)

2018 International Existing Building Code

Add new text as follows:

803.4.4 Smoke Alarms replacement. Where existing smoke alarms in sleeping units of Group I and R occupancies, requiring only a single smoke alarm without interconnection, are to be replaced, ten-year listed sealed battery powered smoke alarms shall be permitted, as an option.

Reason:

1. The 2018 IFC requires smoke alarms in occupancies other than one and two-family dwellings to be replaced if non-functional or when they have reached 10 years of age. ICC Interpretation 01-18 issued 5.15.18 and re-affirmed 8.15.18 expanded that mandate to impact existing smoke alarms in existing buildings. That Interpretation also indicated that such replacement was deemed ‘maintenance’ not ‘construction’.

As such, the IEBC and, in the next cycle the IPMC, are the requisite codes in which to make this change since the IFC specifies construction requirements for smoke alarms. As the IMPC was included in Group A codes, only the IEBC remains available now to amend.

1. History – 10-yr smoke alarms were first allowed in the 2002 edition of NFPA 72, see Sec. 11.6.1(3) and continue to be allowed, see the 2019 edition of NFPA 72 Sec. 29.9.1(3) and 29.9.2.

This technology gained favor among both fire officials and the public as it precluded the removal of the battery (a known factor in residential fire deaths) and avoided the periodic replacement of such batteries, typically annually, for battery only powered smoke alarms or the back-up battery in 120vac powered smoke alarms (often ignored by property owners).

There have been no reported recalls of 10-yr smoke alarms based on a review of the Consumer Product Safety Commission (CPSC) website, see https://cpsc.gov/search?site=cpsc_site&output=xml_no_dtd&getfields=*&tlen=120&client=ek_drupal_01&proxystylesheet=ek_drupal_01&filter=p&query=smoke+alarm+recalls.

As such, 10-yr smoke alarms have a proven track record of reliability.

indicate the reason for smoke alarm failures and subsequent injuries and deaths in fires are most related to the failure to replace a battery for battery only smoke alarms, the failure of the replacement back-up battery for 120vac models when power failures occur and the removal of batteries for other purposes.

The 10yr battery powered smoke alarm removes these failure mode potentials, so is more reliable and is likely to save lives.

NFPA 72 has permitted 10-yr battery only smoke alarms for more than a decade and our Work Group has been directed by the FCAC to align the I-Codes with NFPA 72 to the extent possible.

2. Cost impact - The retail price differential between a traditional smoke alarm (120vac powered with a 9vac battery backup) and 10-yr smoke alarms is about $13 ($35 for the former and $22 for the latter based on retail prices at Home Depot October 2018).

Given the number of commercial occupancies involved (hotels, apartments, condominiums, dormitories, board and care facilities, assistive living facilities and time-shares) the number of smoke alarms to be replaced in the near-term (2019-2022), as the 2018 IFC is adopted state-by-state, is estimated at more than 200 million based on the ten-year age replacement obligation and in such occupancies’ sleeping accommodations where only one smoke alarm is required. The cost savings to those owner/operators is thus estimated at $2.6 billion, if 10-yr smoke alarms technology could replace traditional 120vac/9vac powered smoke alarms.

Bibliography: NFPA 72 -2019 and manufacturerers literature noted.

Cost Impact: The code change proposal will decrease the cost of construction
The proposed code change would decrease the cost of operations for occupances utilizing single station smoke alarms.

Proposal # 5048
IEBC: 803.2.2, 803.2.2.2 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

803.2.2 Groups A, B, E, F-1, H, I-1, I-3, I-4, M, R-1, R-2, R-4, S-1 and S-2. In buildings with occupancies in Groups A, B, E, F-1, H, I-1, I-3, I-4, M, R-1, R-2, R-4, S-1 and S-2, work areas that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with automatic sprinkler protection where both of the following conditions occur:

1. The work area is required to be provided with automatic sprinkler protection in accordance with the International Building Code as applicable to new construction.
2. The work area exceeds 50 percent of the floor area.

Exception: If the building does not have sufficient municipal water supply for design of a fire sprinkler system available to the floor without installation of a new fire pump, work areas shall be protected by an automatic smoke detection system throughout all occupiable spaces other than sleeping units or individual dwelling units that activates the occupant notification system in accordance with Sections 907.4, 907.5 and 907.6 of the International Building Code.

803.2.2.1 Mixed uses. In work areas containing mixed uses, one or more of which requires automatic sprinkler protection in accordance with Section 803.2.2, such protection shall not be required throughout the work area provided that the uses requiring such protection are separated from those not requiring protection by fire-resistance-rated construction having a minimum 2-hour rating for Group H and a minimum 1-hour rating for all other occupancy groups.

Add new text as follows:

803.2.2.2 Group I-2. In Group I-2 occupancies, an automatic sprinkler system installed in accordance with Section 903.3.1.1 of the International Fire Code shall be provided in the following:

1. In Group I-2, Condition 1, throughout the work area.
2. In Group I-2, Condition 2, throughout the work area where the work area is 50 percent or less of the smoke compartment.
3. In Group I-2, Condition 2, throughout the smoke compartment in which the work occurs where the work area exceeds 50 percent of the smoke compartment.

Reason: This change provides a method for determining where sprinklers are required for group I-2 facilities undergoing at least a level 2 alteration. While the IFC already requires fire areas containing Group I-2 to be sprinklered, this change provides a mechanism and encouragement for those facilities coming up to this standard. This language is also consistent with the approach taken by the federal reimbursement agency.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This allows for sprinklers to be added over time, instead of a complete building. This is already required by federal reimbursement requirements.
EB82-19

IEBC®: 803.2.2

Proponent: Kevin Duerr-Clark, New York State Department of State, representing New York State Department of State (kevin.duerr-clark@dos.ny.gov); John Addario, New York State Department of State - Building Standards & Codes, representing New York State Department of State (john.addario@dos.ny.gov)

2018 International Existing Building Code

Revise as follows:

803.2.2 Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 and S-2. In buildings with occupancies in Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 and S-2, work areas that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with automatic sprinkler protection where both of the following conditions occur:

1. The work area is required to be provided with automatic sprinkler protection in accordance with the International Building Code as applicable to new construction.
2. The work area exceeds 50 percent of the floor area.

Exception: If the building does not have sufficient municipal water supply for have an existing municipal water supply present at the floor of the proposed work area, with sufficient pressure and flow for the design of a fire sprinkler system available to the floor without, and without installation of a new fire pump, service piping, or vertical piping, the work areas shall be protected by an automatic smoke detection system throughout all occupiable spaces other than sleeping units or individual dwelling units that activates the occupant notification system in accordance with Sections 907.4, 907.5 and 907.6 of the International Building Code.

Reason: There is some confusion surrounding the language of the exception to this section. Some interpret that “sufficient municipal supply available to the floor” means a water main in the ROW with adequate pressures and flow, and available to tap into with new piping to the building and work area. As supported by the ICC IEBC Interpretation No. 12-04 (see attached), it was never intended for a new water service pipe or vertical/riser pipes to be installed as a requirement for “sufficient municipal supply” to satisfy this code section. The newly proposed language makes it clear that the existing sufficient municipal supply is to exist and be available to the floor where the work area is located without the installation of new service piping, fire pump, or vertical piping.

Commentary to this code section states “One exception to these requirements states that if the building does not have a sufficient municipal water supply for a sprinkler system at the floor where the work area is located, then sprinklers are not required; however, that same exception does require an automatic smoke detection system throughout the work area. The smoke detection coverage is required throughout all occupiable spaces other than areas already required to install smoke alarms.” While useful in understanding this code section, in many cases the Commentary is not available or enforceable. This proposal brings the stated intend of in the Commentary into the actual Code language.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is simply a clarification of the language as already interpreted by ICC and the commentary, so no change in the construction cost is anticipated.
2018 International Existing Building Code

Add new text as follows:

803.2.4 Other required automatic sprinkler systems In buildings and areas listed in Table 903.2.11.6 of the International Building Code, work areas that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with an automatic sprinkler system under the following conditions:

1. The work area is required to be provided with an automatic sprinkler system in accordance with the International Building Code applicable to new construction; and
2. The building has sufficient municipal water supply for design of an automatic sprinkler system available to the floor without installation of a new fire pump.

904.1.4 Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 and S-2 In buildings with occupancies in Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 work areas shall be provided with automatic sprinkler protection where all of the following conditions occur:

1. The work area is required to be provided with automatic sprinkler protection in accordance with the International Building Code as applicable to new construction; and
2. The building site has sufficient municipal water supply for design and installation of an automatic sprinkler system.

904.1.5 Windowless stories Work located in a windowless story, as determined in accordance with the International Building Code, shall be sprinklered where the work area is required to be sprinklered under the provisions of the International Building Code for newly constructed buildings and the building site has a sufficient municipal water supply for the design and installation of an automatic sprinkler system.

Revise as follows:

904.1.6 Other required automatic sprinkler systems. In buildings and areas listed in Table 903.2.11.6 of the International Building Code, work areas that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with an automatic sprinkler system under the following conditions:

1. The work area is required to be provided with an automatic sprinkler system in accordance with the International Building Code applicable to new construction.
2. The building site has sufficient municipal water supply for design and installation of an automatic sprinkler system.

Reason: This proposal backfills Section 803.2.4 to Chapter 8 to fill the void that was unintentionally created in the 2018 cycle (Proposal EB61). Without this change, other areas that require fire protection in the IBC will be missed in Level 2 Alterations.

The two new 904 sections (904.1.4 and 904.1.5) correlate with the new threshold of Level 3 alterations created by (Proposal EB61) 2018 IEBC Section 904.1.4.

The changes to Section 904 fill a void for increased fire protection for Level 3 alterations. The IEBC committee considered three proposals EB59, EB60 and EB61 during the 2018 development cycle. All three lowered the Level 2 threshold from a new fire pump to available water on the site. The membership and committee discussion favored these three proposals but to a Level 3, leaving Level 2 as is. The committee successfully made a modification to move EB61 to Level 3 but was unable to reconsider EB59 & EB60. During the PCH, public comments to correct EB 59 & EB60 failed to receive the 2/3 majority to complete the correlation.

Cost Impact: The code change proposal will increase the cost of construction Level 3 alterations will have an increase of initial fire protection cost, however, there are other cost-neutral or cost-reducing measures fire protection systems provide in the model codes and community risk reduction.
2018 International Existing Building Code

Revise as follows:

803.4.1 Occupancy requirements. A fire alarm system shall be installed in accordance with Sections 803.4.1.1 through 803.4.1.6. Existing alarm-notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm-notification appliances within the work area shall be provided and automatically activated.

Exceptions:

1. Occupancies with an existing, previously approved fire alarm system.
2. Where selective notification is permitted, alarm-notification appliances shall be automatically activated in the areas selected.

Add new text as follows:

803.4.1.1 Fire alarm control unit. Where the building is not equipped with a fire alarm system, the following shall apply:
   1. A building fire alarm control unit/system shall be provided with an annunciator installed at an approved location.
   2. All fire alarm system requirements in Work Areas in the building shall be connected into the building fire alarm control unit/system.

803.4.1.2 Initiating and notification devices. Where the building is equipped with a fire alarm system, all fire alarm system initiating, and notification devices required in the work area shall be connected into the existing fire alarm control unit/system.

Reason: An existing building without a fire alarm system, when following the existing language will have multiple fire alarm panels scattered throughout the building, based on the fire alarm system/panel being installed only for that Work Area. This code change will require a “building” fire alarm panel be installed with the first Work Area. From that point on all additional work will be tied into the building fire alarm panel. This will be more cost effective over time, and provide the minimum level of life safety for the building occupants and first responders.

Cost Impact: The code change proposal will increase the cost of construction.

The initial cost of the fire panel will be borne by the first tenant/work area/owner. This will depend on the size of the building. Could be a 5 to 10K cost.
2018 International Existing Building Code

Add new text as follows:

803.4.1.1 Extent of installation. Audible/visual notification appliances shall be provided in accordance with this code for the work area and the entire common area of the floor or fire area, and shall be connected to the building fire alarm control unit/system.

Reason: In addition for the need for a fire alarm control unit as addressed in the first IEBC alarm proposal this will require that the common areas of the entire floor or fire area be provided with notification appliances so when a fire is detected the occupants will receive a level of notification.

Cost Impact: The code change proposal will increase the cost of construction. Will depend on the number of notification devices and the size of the floor area. Estimate about 390.00 per device installed.
EB86-19
IEBC®: 803.4.1.2 (New), 803.4.1.3 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code
Revise as follows:

803.4.1.2 Group I-1. A An automatic fire alarm system shall be installed in work areas of Group I-1 residential care/assisted living facilities as required by Chapter 11 of the International Fire Code for existing Group I-1 occupancies.

803.4.1.3 Group I-2. A An automatic fire alarm system shall be installed throughout Group I-2 occupancies as required by Chapter 11 of the International Fire Code.

Reason: This is coordination with the requirements in the International Fire Code for existing buildings. The term "residential care/assisted living" is no longer used in the code. Leaving it in this section is confusing. This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction This is consistent with requirements already in IFC.

Proposal # 4277
Proponent: Jeffrey Hugo, National Fire Sprinkler Association, representing National Fire Sprinkler Association (hugo@nfsa.org)

2018 International Existing Building Code
Revise as follows:

805.3.1.1 Single-exit buildings. A single exit or access to a single exit shall be permitted from spaces, any story or any occupied roof where one of the following conditions exists:

1. The occupant load, number of dwelling units and exit access travel distance do not exceed the values in Table 805.3.1.1(1) or 805.3.1.1(2).
2. In Group R-1 or R-2, nonsprinklered buildings without an approved automatic sprinkler system, individual single-story or multiple-story dwelling or sleeping units shall be permitted to have a single exit or access to a single exit from the dwelling or sleeping unit provided one of the following criteria are met:
   2.1. The occupant load is not greater than 10 and the exit access travel distance within the unit does not exceed 75 feet (22 860 mm).
   2.2. The building is not more than three stories in height; all third-story space is part of dwelling with an exit access doorway on the second story; and the portion of the exit access travel distance from the door to any habitable room within any such unit to the unit entrance doors does not exceed 50 feet (15 240 mm).
3. In buildings of Group R-2 occupancy of any number of stories with not more than four dwelling units per floor served by an interior exit stairway; with a smokeproof enclosure in accordance with Sections 909.20 and 1023.11 of the International Building Code or an exterior stairway as an exit; and where the portion of the exit access travel distance from the dwelling unit entrance door to the exit is not greater than 20 feet (6096 mm).

<table>
<thead>
<tr>
<th>STORY</th>
<th>OCCUPANCY</th>
<th>MAXIMUM NUMBER OF DWELLING UNITS</th>
<th>MAXIMUM EXIT ACCESS TRAVEL DISTANCE (feet)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basement, first or second story above grade plane</td>
<td>R-2</td>
<td>4 dwelling units</td>
<td>50</td>
</tr>
<tr>
<td>Third story above grade plane and higher</td>
<td>NP</td>
<td>NA</td>
<td>NA</td>
</tr>
</tbody>
</table>

For SI: 1 foot = 304.8 mm.

NP = Not Permitted.

NA = Not Applicable.

a. Group R-2, nonsprinklered without an approved automatic sprinkler system and provided with emergency escape and rescue openings in accordance with Section 1030 of the International Building Code.

1301.6.17 Automatic sprinklers. Evaluate the ability to suppress or control a fire based on the installation of an automatic sprinkler system in accordance with Section 903.1.1-903.3.1 of the International Building Code. “Required sprinklers” shall be based on the requirements of the code, the International Building Code. Under the categories and occupancies in Table 1301.6.17, determine the appropriate value and enter that value into Table 1301.7 under Safety Parameter 1301.6.17, Automatic Sprinklers, for fire safety, means of egress divided by 2, and general safety. High-rise buildings defined in Chapter 2 of the International Building Code that undergo a change of occupancy to Group R shall be equipped throughout with an automatic sprinkler system in accordance with Section 403 of the International Building Code and Chapter 9 of the International Building Code. Facilities in Group I-2 occupancies meeting Category a, b, c or f shall be considered to fail the evaluation.

1301.6.17.1 Categories. The categories for automatic sprinkler system protection are:

1. Category a—Sprinklers are not provided. An approved automatic sprinkler system is required throughout; an approved automatic sprinkler system is not provided.
2. Category b—An approved automatic sprinkler system is required in a fire area or compartment; an approved automatic sprinkler system is not provided; sprinkler protection is not provided or the sprinkler system design is not adequate for the hazard protected in accordance with Section 903 of the International Building Code. Category b—Sprinklers are required in a portion of the building; sprinkler protection is not provided or the sprinkler system design is not adequate for the hazard protected in accordance with Section 903 Chapter 9 of the International Building Code.
3. Category e—Sprinklers are c—An approved automatic sprinkler system is not required; none are provided.
4. Category d—Sprinklers are d—An approved automatic sprinkler system is required in a portion of the building; sprinklers are provided in such portion; the system is one that complied with the code at the time of installation and is maintained and supervised in accordance with Section 903—fire area or compartment; an approved automatic sprinkler system is provided in a fire area or compartment in accordance with Chapter 9 of the International Building Code.
5. Category e—Sprinklers are e—An approved automatic sprinkler system is required throughout; sprinklers are an approved automatic sprinkler system is provided throughout in accordance with Chapter 9 of the International Building Code.
6. Category f—Sprinklers are f—An approved automatic sprinkler system is not required throughout; sprinklers are an approved automatic sprinkler system is provided throughout in accordance with Chapter 9 of the International Building Code.

Reason: IEBC 805.3.1.1:
An "unsprinklered" building is not defined and is a subjective term. This proposal uses terms that are defined and correlate to the other ICC codes.

IEBC 1301.6.17:
These changes swap the term "sprinklers" with the defined terms of "approved" and "automatic sprinkler system" to correlate to the other ICC codes. Below are specific reasons for each text change:

"...or control..." This change correctly addresses automatic fire sprinkler systems for the majority of installations. Fire sprinkler systems designed according to NFPA 13, NFPA 13R and NFPA 13D are designed to control fires. There are a few instances where the fire sprinkler is designed to suppress fires, such as in storage occupancies. It is appropriate to have "control" more than suppression in the code text, but this proposal leaves suppression in to accommodate the suppression in storage occupancies...."

"...Section 903.3.1.1..."This change removes the limitation of the values to be used just on a NFPA 13 system. The values cannot be limited to just NFPA 13 systems. The intent of the proposal that expanded the values for 1996 BOCA did not prohibit NFPA 13R systems (B213-95), likewise, the values table has occupancies that are permitted to use NFPA 13R (R-1, R-2) and NFPA 13D (R-3, R-4) systems. When a building is sprinklered according to any of the sprinkler standards, they are considered fully sprinklered.

"...the International Building Code..." When this section was located in the IBC it also stated "this code". This section wasn't revised when it moved from the IBC to the IEBC. Every other section in Chapter 14 of the IEBC that has similar language refers to the IBC. For example, IEBC Section 1401.6.18 refers the requirements back to the IBC. this code..."

" Category a" This change updates and clarifies where sprinklers are throughout to make the user aware of the extent of sprinklers protection. The latter portion of the text is removed. The value assigned to this is extreme and is redundant with Category b. Having no sprinklers and an under-designed system is not equal. Both are detrimental, but one has no protection, the other has some form of protection. The penalty for an under-designed system should a Category b and keep the unsprinklered building as the highest penalty.

"Category b" This change provides a negative value when a fire area or compartment that is required to have sprinklers, but doesn't. Fire areas are defined in the IBC and "compartments" are used and qualified in Section 1301.6.3. These terms are concrete and have definite passive fire protection boundaries than the subjective term "portion". By using fire area and compartments, the code official and the user can be clear where sprinklers are supposed to be installed. There are some occupancies, such as A-1, A-2, A-3 and A-4, that are only required to have sprinklers in the fire area. Other fire areas may not need fire sprinklers. This change would provide buildings with sprinklered fire areas some credit. The value would not apply to a partial systems for incidental uses or other partial or limited-area system installation. The value would only be applied when the fire areas that are supposed to have sprinklers are installed according to the appropriate standard, or when the compartment is sprinklered.

"Category d" This change assigns the partial system for a fire area with a value. It also removes the undefined term "portion". Fire areas are defined in the IBC and "compartments" are used and qualified in Section 1301.6.3. These terms are concrete and have definite passive fire protection boundaries than the subjective term "portion" which will have differing boundaries by every user for every building that is evaluated. By using fire area and compartments, the code official and the user can be clear where sprinklers are supposed to be installed. This proposal also removes the value that is assigned for the maintenance of the system according to the edition of the standard when it was installed. The IBC and IFC along with NFPA 13 require the sprinkler system to be maintained according to NFPA 25. This may not have been clear when the proposal was drafted for the 1996 BOCA. NFPA 25 was a new standard in 1992 and while it was referenced by the BOCA Fire Prevention Code, the scope may not have been fully understood and enforcement was difficult if the BOCA Fire Prevention Code was not specifically adopted.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
No cost impact, correlative change.
2018 International Existing Building Code

Revise as follows:

805.4.1.2 Group I-2. In buildings of Group I-2 occupancy, any patient sleeping room or suite of patient rooms greater than 1,000 square feet (93 m²) within the work area shall have not fewer than two egress doorways. Condition 2, work areas that include altered care suites shall comply with Sections 407.4.4 through 407.4.4.6.2 of the International Building Code.

Reason: The existing language of this paragraph only references patient sleeping rooms. It is important to define the limit of a suite requiring two exits beyond the sleeping rooms, because hospitals also utilize suites that do not sleep patients, but are used for treatment. This proposal captures the 2,500 square-foot limit already established by the federal standard. This change is limited to I-2, Condition 2 (hospitals) because suites are not widely used in the nursing home or post-acute care setting.

IFC 1105.8 Group I-2 care suites. Care suites in existing GroupI-2, Condition 2 occupancies shall comply with Sections 407.4.4 through 407.4.4.6.2 of the International Building Code.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction Group I-2, Condition occupancies already conform to this requirement.
Proponent: Jonathan Roberts, UL LLC, representing UL LLC (jonathan.roberts@ul.com)

2018 International Existing Building Code

Revise as follows:

805.4.4 Panic and fire exit hardware. In any work area, and in the egress path from any work area to the exit discharge, in buildings or portions thereof of Group A assembly occupancies with an occupant load greater than 100, all required exit doors equipped with latching devices shall be equipped with approved panic hardware, or fire exit hardware in accordance with Section 1010.1.10 of the International Building Code.

Reason: Fire exit hardware should be included as an approved option in these requirements for those installations where the hardware is used on a fire door. Both panic hardware and fire exit hardware are life safety devices, and should be installed in accordance with the requirements in Chapter 10 of the IBC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There are numerous panic and fire exit hardware that already comply with Section 1010.1.10, so when these are used there will be no increase in costs.
EB90-19

IEBC®: 805.5.3

**Proponent:** Allison Cook, representing VBCOA; Ronald Clements Jr, representing Chesterfield County (clementsro@chesterfield.gov); Kenney Payne, Moseley Architects, representing AIA Virginia (kpayne@moseleyarchitects.com); Charles Vernon, representing VBCOA (cvernon@arlingtonva.us); Debra McMahon (debra.mcmahon@fairfaxcounty.gov); Michael Williams (mike.williams@harrisonburgva.gov); Christina Jackson, representing City of Norfolk / WICED of VA (christina.reynolds@norfolk.gov)

**2018 International Existing Building Code**

Revise as follows:

805.5.3 Other corridor openings. In any work area, unless otherwise protected or fire-resistant rated in accordance with Section 716 of the IBC, any other sash, grille, or opening in a corridor and any window in a corridor not opening to the outside air shall be sealed with materials consistent with the corridor construction.

**Reason:** As currently written, the provision states that any other corridor opening shall be sealed. This is regardless of the level of protection that might already exist. So, an otherwise code-compliant opening or window would still need to be sealed. Sealing should only be required when such protection or rating is not already provided in accordance with the IBC.

**Cost Impact:** The code change proposal will decrease the cost of construction. This proposal could result in cost decrease by eliminating unnecessary sealing of otherwise compliant openings.

Proposal #5554
2018 International Existing Building Code

Revise as follows:

805.6 Dead-end corridors. Dead-end corridors in any work area shall not exceed 35 feet (10 670 mm). In Group I-2 occupancies, dead-end corridors shall not exceed 30 feet (9144 mm).

Exceptions:

1. Where dead-end corridors of greater length are permitted by the International Building Code.
2. In other than Group A, I-2 and H occupancies, the maximum length of an existing dead-end corridor shall be 50 feet (15 240 mm) in buildings equipped throughout with an automatic fire alarm system installed in accordance with the International Building Code.
3. In other than Group A, I-2 and H occupancies, the maximum length of an existing dead-end corridor shall be 70 feet (21 356 mm) in buildings equipped throughout with an automatic sprinkler system installed in accordance with the International Building Code.
4. In other than Group A, I-2 and H occupancies, the maximum length of an existing, newly constructed, or extended dead-end corridor shall not exceed 50 feet (15 240 mm) on floors equipped with an automatic sprinkler system installed in accordance with the International Building Code.

Reason: For I-2 occupancies, a 30 foot corridor is required by the federal standard. If the subject corridor is within the work area of Level 2 construction, it is appropriate for work to be done to modify it to conform with that standard. This is consistent with what is currently permitted under IFC 1105.6.5.

IFC 1105.6.5 Dead-end corridors. In smoke compartments containing patient sleeping rooms and treatment rooms, dead-end corridors shall not exceed 30 feet (9144 mm) unless approved by the fire code official.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including; meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will increase the cost of construction. This code change will add construction cost, because additional modification to the corridor would be required to reduce the dead end from 35 to 30 feet.

Proposal # 4250
IEBC®: SECTION 809, 809.1, 1009.1

Proponent: Allison Cook, Arlington, VA, representing myself; Christina Jackson, representing City of Norfolk / WICED of VA (christina.reynolds@norfolk.gov)

2018 International Existing Building Code
Delete without substitution:

SECTION 809-
PLUMBING

809.1 Minimum fixtures. Where the occupant load of the story is increased by more than 20 percent, plumbing fixtures for the story shall be provided in quantities specified in the International Plumbing Code based on the increased occupant load.

Revise as follows:

1009.1 Increased demand. Where the occupancy of an existing building or part of an existing building is changed such that the new occupancy is subject to increased or different plumbing fixture requirements or to increased water supply requirements in accordance with the International Plumbing Code, the new occupancy shall comply with the intent of the respective International Plumbing Code provisions.

Exception: Only where the occupant load of the story is increased by more than 20 percent, plumbing fixtures for the story shall be provided in quantities specified in the International Plumbing Code based on the increased occupant load.

Reason: The change of occupancy definition includes “Change of occupancy includes the language “any change in use within a group for which there is a change in the application of the requirements of this code” So, an increase in occupant load of 20% is a change of occupancy. This does not belong in a level 2 alteration. Relocating this code section as an exception under the change of occupancy reduces confusion about what is or is not a change of occupancy. It also eliminates the conflict between section 809.1 (which essentially says you can increase occupant load without adding fixtures) and section 1009.1 (which says requires tenants to add fixtures if the IPC requires a greater fixture quantity or different type)

Cost Impact: The code change proposal will decrease the cost of construction
Applying this section to all change of occupancy will reduce the requirement to add plumbing fixtures to existing tenant spaces.

Proposal # 5439
EB93-19

IEBC®: 904.2, 904.2.1, 904.2.2

Proponent: Dan Finnegan, Siemens, representing Self (daniel.finnegan@siemens.com)

2018 International Existing Building Code

Revise as follows:

904.2 Fire alarm and detection systems. Fire alarm and detection shall be provided in accordance with Section 907 of the International Building Code as required for new construction.

904.2.1 Manual fire alarm systems. Where required by the International Building Code, a manual fire alarm system shall be provided throughout the work area. Alarm notification appliances shall be provided on such floors and shall be automatically activated as required by the International Building Code.

Exceptions:

1. Alarm-initiating and notification appliances devices shall not be required to be installed in tenant spaces outside of the work area.
2. Visual alarm notification appliances are not required, except where an existing alarm system is upgraded or replaced or where a new fire alarm system is installed.

904.2.2 Automatic fire detection. Where required by the International Building Code for new buildings, automatic fire detection systems shall be provided throughout the work area.

Reason: This proposal follows the life safety concept in the other IEBC alarm proposal that requires installation of audible and visual notification appliances beyond the work area for level 2 alterations. When a work area is on a floor, the exception will state only alarm initiating devices are not needed outside the space of the work area. It will require the notification appliances to be installed outside the work area to provide proper notification to occupants at risk when an alarm initiating device has been activated.

Cost Impact: The code change proposal will increase the cost of construction
Will depend on the number of notification devices and the size of the floor area. Estimate about 390.00 per device installed
2018 International Existing Building Code

SECTION 905
MEANS OF EGRESS

905.1 General. The means of egress shall comply with the requirements of Section 805 except as specifically required in Sections 905.2 and 905.3.

905.2 Means-of-egress lighting. Means of egress from the highest work area floor to the floor of exit discharge shall be provided with artificial lighting within the exit enclosure in accordance with the requirements of the International Building Code.

905.3 Exit signs. Means of egress from the highest work area floor to the floor of exit discharge shall be provided with exit signs in accordance with the requirements of the International Building Code.

Add new text as follows:

905.4 Two-way communications systems. In buildings with elevator service, a two way communication systems shall be provided in accordance with Section 1009.8 of the International Building Code.

SECTION 503
ALTERATIONS

503.17 Two-way communications systems. Where the work area for alterations exceeds 50 percent of the building area and the building has elevator service, a two way communication systems shall be provided in accordance with Section 1009.8 of the International Building Code.

Reason: The addition of Sections 503.7 and 905.4 would allow for a person who could not use the stairways for evacuation to at least have a way to contact emergency responders. Since this is only alteration of Level 3 or exceeds 50% of the building area, this would have minimal impact on the construction and would be a big boost for persons who needed assistance in evacuation and the fire department.

Cost Impact: The code change proposal will increase the cost of construction
A two way communication system may need to be added in older multi-story buildings that were undergoing Level 3 alterations.

Proposal # 4417
IEBC: SECTION 908 (New), 908.1 (New), 1010.2 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

Add new text as follows:

**SECTION 908**

**EMERGENCY RESPONDER RADIO COVERAGE**

908.1 Emergency responder radio coverage in existing buildings. Where existing buildings do not have an approved emergency responder radio coverage in the building based on existing coverage levels of the public safety communication systems, an approved emergency responder radio coverage system shall be installed within the building in compliance with Section 510 of the International Fire Code.

**SECTION 1010**

**OTHER REQUIREMENTS**

1010.1 Light and ventilation. Light and ventilation shall comply with the requirements of the International Building Code for the new occupancy.

Add new text as follows:

1010.2 Emergency responder radio coverage in existing buildings. Where an existing building undergoes a complete change of occupancy, and the building does not have an approved emergency responder radio coverage based on existing coverage levels of the public safety communication systems, an approved emergency responder radio coverage system shall be installed within the building in compliance with Section 510 of the International Fire Code. The system shall be installed within the time frame established by the code official.

**Reason:** For jurisdictions that do not adopt the Chapter 11 (retroactive) requirements of the IFC for Emergency Responder Radio Coverage, this proposal would add triggers to the IEBC that would require all existing buildings that undergo a Level 3 alteration or Change of Occupancy to have approved radio coverage. Providing these two triggers for Emergency Responder Radio Coverage provides a reasonable opportunity to install equipment and systems that ensure the safety of emergency responders that depend on reliable communication for their safety. We are not asking for this in a building undergoing a partial change of occupancy with a Level 1 or 2 alteration because that could be only one tenant in a very large multi-tenant building. IFC Section 510 includes all the requirements for the design and installation. Allowing for a time frame for installation in a COO is consistent with IFC Section 1103.2.

This proposal will correlate consistency between the IFC and the IEBC as it relates to the requirements for emergency responder radio coverage in existing buildings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will increase the cost of construction

For the safety of emergency responders, a system may need to be added in some of the larger buildings.
EB96-19

IEBC®: 1002.1, 1002.2

**Proponent:** Allison Cook, representing VBCOA; Ronald Clements Jr, representing Chesterfield County (clementsro@chesterfield.gov); Kenney Payne, Moseley Architects, representing AIA Virginia (kpayne@moseleyarchitects.com); Charles Vernon, representing VBCOA (cvernon@arlingtonva.us); Debra McMahon (debra.mcmahon@fairfaxcounty.gov); Christina Jackson, representing City of Norfolk / WICED of VA (christina.reynolds@norfolk.gov)

**2018 International Existing Building Code**

Revise as follows:

**1002.1 Compliance with the building code.** Where the character or use of an existing building or part of an existing building is changed undergoes a change of occupancy to one of the following special use or occupancy categories as defined described in Chapter 4 in the International Building Code, the building shall comply with all of the applicable requirements of Chapter 4 of the International Building Code applicable to the special use or occupancy:

1. Covered and open mall buildings.
2. Atriums.
3. Motor vehicle-related occupancies.
4. Aircraft-related occupancies.
5. Motion picture projection rooms.
6. Stages and platforms.
7. Special amusement buildings.
8. Incidental use areas.
10. Ambulatory care facilities.

**1002.2 Underground buildings.** Incidental uses. An underground building in which there is a change of occupancy to one of the incidental uses listed in Table 509 of the International Building Code, the incidental use shall comply with the requirements of Section 509 of the International Building Code applicable to underground structures, the incidental use.

**Reason:** 1002.1- The special use and occupancy section listed some of the special uses addressed in IBC chapter 4 but not all. The commentary suggest that the specific list is for special uses that would not constitute a change in classification and are necessary because a change in occupancy without a change in classification would not invoke the chapter 4 requirements. The current definition of change of occupancy includes a change in use where there is a change in application of code regardless of whether there is a classification change; therefore, the list is no longer necessary. As currently written, regardless of whether a change of classification is involved in a change of occupancy, special use provisions in IBC chapter 4 would not be applicable to any special uses that are not in the list in IEBC chapter 10. This change simplifies the requirement and brings in all of the potential special use hazards that should be mitigated in a change of occupancy involving one of the special uses.

1002.2- Underground structures are a special use per IBC chapter 4 so the change proposed for 1002.1 covers underground buildings. Incidental uses are not special uses addressed by IBC chapter 4 so listing incidental uses in 1002.1 was out of place and will be lost with the proposed amendment to 1002.1; therefore, 1002.2 is proposed to capture the incidental use requirement.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The code change proposal will not increase or decrease the cost of construction since the commentary suggested that all of IBC Chapter 4 was already applicable.

Proposal # 5556
EB97-19

IEBC®: 1002.1 (New), 1011.1.4 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

1002.1 Compliance with the building code. Where the character or use of an existing building or part of an existing building is changed to one of the following special use or occupancy categories as defined in the International Building Code, the building shall comply with all of the applicable requirements of the International Building Code:

1. Covered and open mall buildings.
2. Atriums.
3. Motor vehicle-related occupancies.
4. Aircraft-related occupancies.
5. Motion picture projection rooms.
6. Stages and platforms.
7. Special amusement buildings.
8. Incidental use areas.
10. Ambulatory care facilities.

Add new text as follows:

1011.1.4 Change of occupancy in Healthcare. Where a change of occupancy occurs to a Group I-2 or I-1 facility, the work area with the change of occupancy shall comply with the International Building Code.

Exception: A change in use or occupancy in the following cases shall not be required to meet the International Building Code:

1. Group I-2 Condition 2 to Group I-2 Condition 1
2. Group I-2 to ambulatory healthcare.
3. Group I-2 to Group I-1
4. Group I-1 Condition 2 to a Group I-1 Condition 1

Reason: The most obvious effect of this proposal is to move the discussion regarding Group I-2 occupancies to its own section. This is needed because we are proposing a few exceptions that would only apply to this occupancy class. This proposal also accomplishes two technical changes:

1. It identifies that building converting to a Group I-1 occupancies need careful consideration. There are some special requirements for that occupancy that should be applied during a change of occupancy. For example, group I-1 condition 2 facilities are required to have smoke compartments. Current language would not trigger this requirement. Specifically, the special requirements include Chapter 4 (smoke compartmentation, fire partitions), chapter 9 (sprinkler requirements), and chapter 10 (limitations on the means of egress systems). Due to the special character and risk in Group I-1, we believe these building code provisions should be applied at any change of occupancy.

2. This change also creates a few exceptions to the application of new building code requirements. The current federal requirements allow the “downgrade” of medical facilities from a more intensive to less intensive use. In effect, this encourages older hospitals to become nursing homes and ambulatory surgery facilities; older nursing homes to become assisted living facilities; etc.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The addition of Group I-1 would increase the cost of construction. The exceptions for Group I-2 would reduce the cost of construction.
2018 International Existing Building Code

Add new text as follows:

1002.2 Storage. In Group I-2 occupancies, equipped throughout with an automatic sprinklered in accordance with Section 903.3.1.1, where a room 250 ft² (23.2 m²) or less undergoes a change in occupancy to a storage room, the room shall be separated from the remainder of the building by construction capable of resisting the passage of smoke in accordance with Section 509.4.2 of the International Building Code.

Reason: In buildings of Group I-2, the IBC requires 1 hr separation for such storage rooms for new construction, the IFC only requires construction capable of resisting the passage of smoke when the storage room is protected with an automatic sprinkler system. With the presence of automatic sprinkler protection, the disruption associated with replacing the walls with one-hour fire barriers is not necessary for an act that occurs quite frequently (converting spaces to/from storage spaces quite frequently).

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Permits operation change without having to comply with incidental use requirements.
Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

1007.1 Special occupancies. Where the occupancy of an existing building or part of an existing building is changed to one of the following special occupancies as described in NFPA 70, the electrical wiring and equipment of the building or portion thereof that contains the proposed occupancy shall comply with the applicable requirements of NFPA 70 whether or not a change of occupancy group is involved. Health care facilities, including Group I-2, ambulatory healthcare facilities and outpatient clinics, shall also comply with the applicable requirements of NFPA 99.

1. Hazardous locations.
2. Commercial garages, repair and storage.
3. Aircraft hangars.
4. Gasoline dispensing and service stations.
5. Bulk storage plants.
7. Health care facilities, including Group I-2, ambulatory healthcare facilities and outpatient clinics.
9. Theaters, audience areas of motion picture and television studios, and similar locations.
10. Motion picture and television studios and similar locations.
11. Motion picture projectors.

Reason: NFPA 99 specifies additional requirements for electrical systems in health care facilities than just NFPA 70. In order to meet federal conditions of participation health care facilities must comply with the electrical systems and equipment must be installed according to the requirements listed in NFPA 99, Health Care Facilities Code (K901, K911, and K916). This change will align the electrical systems installation requirements for Outpatient Clinics, Group B Ambulatory Care and Group I-2 facilities. NFPA 99 uses a risk based approach to system design, installation and maintenance in healthcare facilities (Group I-2 facilities, ambulatory care facilities and outpatient clinics). Four levels of systems categories are defined in NFPA 99, based on the risks to patients and caregivers in the facilities. The categories are as follows:

(1) Category 1: Systems that are expected to be functional at all times. Failure of these systems is likely to cause major injury or death.

(2) Category 2: Systems are expected to have a high level of reliability. Failures of these systems are likely to cause minor injury to patients or caregivers, however, limited short durations of equipment downtime can be tolerated. Category 2 systems are not critical for life support.

(3) Category 3: Normal building system reliabilities are expected. Such systems support patient needs, but failure of such equipment or systems would not immediately affect patient care and are not critical for life support.

(4) Category 4: Such systems have no impact on patient care and would not be noticeable to patients in the event of failure.

The category definitions apply to equipment and systems operations.

A risk assessment should be conducted to evaluate the risk to the patients, staff, and visitors in all healthcare facilities. These categories are not always aligned to occupancy classification. Potential examples of areas/systems and their categories of risk;

(1) Ambulatory surgical center, where patients undergo general anesthesia, Category 1

(2) Reconstructive surgeon's office with general anesthesia, Category 1

(3) Procedural sedation site for outpatient services, Category 2

(4) Cooling systems in Houston, TX, Category 2

(5) Cooling systems in Seattle, WA, Category 3

(6) Heating systems in Chicago, IL Category 2
(7) Dental office, no general anesthesia, Category 3

(8) Typical doctor’s office/exam room, Category 4

(9) Group I-2 Condition 2 facilities most systems would be Category 1

This approach more closely aligns system design, performance and maintenance to the safety risk to the public. It does not create significant additional costs.

This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This change aligns with existing federal requirements for the healthcare industry.
EB100-19

IEBC®: 1009.5 (New)

Proponent: John Williams, representing Healthcare Committee (AHC@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

1009.5 Group I-2. If the occupancy group is changed to Group I-2, the plumbing system and medical gas system shall comply with the applicable requirements of the International Plumbing Code.

Reason: The International Plumbing Code includes medical gas system requirements which are important to comply in many I-2 occupancies. The International Plumbing code provides guidance for medical gas systems to comply with federal guidelines (K903). This proposal is submitted by the ICC Committee on Healthcare (CHC). The CHC was established by the ICC Board to evaluate and assess contemporary code issues relating to healthcare facilities. This is a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. In 2017 and 2018 the CHC held 4 open meetings and numerous conference calls, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Information on the CHC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CHC effort can be downloaded from the CHC website at: https://www.iccsafe.org/codes-tech-support/cs/icc-committee-on-healthcare/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change aligns with existing federal requirements for the healthcare industry.
EB101-19 Part I

PART I — IEBC: 1011.4.1, 1011.4.6 (New), 506.4 (New); IRC: R310.5, R310.6, 310.9.1 (New)

PART II — IRC®: SECTION R310 (New), R310.5 (New), R310.6 (New), R310.9.1 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@icc.org)

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART I WILL BE HEARD THE IEBC COMMITTEE, PART II WILL BE HEARD BY THE IRC-BUILDING COMMITTEE. PLEASE SEE THE TENTATIVE HEARING ORDERS FOR THE RESPECTIVE COMMITTEES.

2018 International Existing Building Code

Revise as follows:

SECTION 1011
CHANGE OF OCCUPANCY CLASSIFICATION

1011.4 Means of egress, general. Hazard categories in regard to life safety and means of egress shall be in accordance with Table 1011.4.

TABLE 1011.4
MEANS OF EGRESS HAZARD CATEGORIES

<table>
<thead>
<tr>
<th>RELATIVE HAZARD</th>
<th>OCCUPANCY CLASSIFICATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (Highest Hazard)</td>
<td>H</td>
</tr>
<tr>
<td>2</td>
<td>I-2; I-3; I-4</td>
</tr>
<tr>
<td>3</td>
<td>A; E; I-1; M; R-1; R-2; R-4, Condition 2</td>
</tr>
<tr>
<td>4</td>
<td>B; F-1; R-3; R-4, Condition 1; S-1</td>
</tr>
<tr>
<td>5 (Lowest Hazard)</td>
<td>F-2; S-2; U</td>
</tr>
</tbody>
</table>

1011.4.1 Means of egress for change to a higher-hazard category. Where a change of occupancy classification is made to a higher-hazard category (lower number) as shown in Table 1011.4, the means of egress shall comply with the requirements of Chapter 10 of the International Building Code.

Exceptions:

1. Stairways shall be enclosed in compliance with the applicable provisions of Section 903.1.
2. Existing stairways including handrails and guards complying with the requirements of Chapter 9 shall be permitted for continued use subject to approval of the code official. Any stairway replacing an existing stairway within a space where the pitch or slope cannot be reduced because of existing construction shall not be required to comply with the maximum riser height and minimum tread depth requirements.
3. Existing corridor walls constructed on both sides of wood lath and plaster in good condition or 1/2 inch-thick (12.7 mm) gypsum wallboard shall be permitted. Such walls shall either terminate at the underside of a ceiling of equivalent construction or extend to the underside of the floor or roof next above.
4. Existing corridor doors, transoms and other corridor openings shall comply with the requirements in Sections 805.5.1, 805.5.2 and 805.5.3.
5. Existing corridor doors, transoms and other corridor openings shall comply with the requirements in Sections 805.6.
6. An existing operable window with clear opening area not less than 4 square feet (0.38 m²) and minimum opening height and width of 22 inches (559 mm) and 30 inches (762 mm), respectively, operable window complying with Section 1011.4.6, shall be accepted as an emergency escape and rescue opening.

1011.4.2 Means of egress for change of use to an equal or lower-hazard category. Where a change of occupancy classification is made to an equal or lesser-hazard category (higher number) as shown in Table 1011.4, existing elements of the means of egress shall comply with the requirements of Section 905 for the new occupancy classification. Newly constructed or configured means of egress shall comply with the requirements of Chapter 10 of the International Building Code.

Exception: Any stairway replacing an existing stairway within a space where the pitch or slope cannot be reduced because of existing construction shall not be required to comply with the maximum riser height and minimum tread depth requirements.

1011.4.3 Egress capacity. Egress capacity shall meet or exceed the occupant load as specified in the International Building Code for the new occupancy.

1011.4.4 Handrails. Existing stairways shall comply with the handrail requirements of Section 805.9 in the area of the change of occupancy.
classification.

1011.4.5 Guards. Existing guards shall comply with the requirements in Section 805.11 in the area of the change of occupancy classification.

Add new text as follows:

1011.4.6 Existing emergency escape and rescue openings. Where a change of occupancy would require emergency escape and rescue opening in accordance with Section 1030.1 of the International Building Code, operable windows serving as the emergency escape and rescue opening shall comply with the following:

1. An existing operable window shall provide a minimum net clear opening of 4 square feet (0.38 m²) with a minimum net clear opening height of 22 inches (559 mm) and a minimum net clear opening width of 20 inches (508 mm).

2. A replacement window where such window complies with both of the following:
   2.1. The replacement window meets the size requirements in Item 1.
   2.2. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

Revise as follows:

SECTION 506
CHANGE OF OCCUPANCY

506.3 Stairways. An existing stairway shall not be required to comply with the requirements of Section 1011 of the International Building Code where the existing space and construction does not allow a reduction in pitch or slope.

Add new text as follows:

506.4 Existing Emergency escape and rescue openings. Where a change of occupancy would require emergency escape and rescue opening in accordance with Section 1030.1 of the International Building Code, operable windows serving as the emergency escape and rescue opening shall comply with the following:

1. An existing operable window shall provide a minimum net clear opening of 4 square feet (0.38 m²) with a minimum net clear opening height of 22 inches (559 mm) and a minimum net clear opening width of 20 inches (508 mm).

2. A replacement window where such window complies with both of the following:
   2.1. The replacement window meets the size requirements in Item 1.
   2.2. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
2018 International Residential Code
Revise as follows:

SECTION R310
EMERGENCY ESCAPE AND RESCUE OPENINGS

R310.5 Dwelling additions. Where dwelling additions contain sleeping rooms, an emergency escape and rescue opening shall be provided in each new sleeping room. Where dwelling additions have basements, an emergency escape and rescue opening shall be provided in the new basement.

Exceptions:

1. An emergency escape and rescue opening is not required in a new basement that contains a sleeping room with an emergency escape and rescue opening.
2. An emergency escape and rescue opening is not required in a new basement where there is an emergency escape and rescue opening in an existing basement that is accessed from the new basement.
3. An operable window complying with Section 310.9.1 shall be acceptable as an emergency escape and rescue opening.

R310.6 Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing basements undergo alterations or repairs.

Exception: New sleeping rooms created in an existing basement shall be provided with emergency escape and rescue openings in accordance with Section R310.1. Other than new sleeping rooms, where existing basements undergo alterations or repairs an emergency escape and rescue opening is not required.

Add new text as follows:

R310.9.1 Existing Emergency escape and rescue openings. Where a change of occupancy would require emergency escape and rescue opening in accordance with Section 310.1, operable windows serving as the emergency escape and rescue opening shall comply with the following:

1. An existing operable window shall provide a minimum net clear opening of 4 square feet (0.38 m²) with a minimum net clear opening height of 22 inches (559 mm) and a minimum net clear opening width of 20 inches (508 mm).
2. A replacement window where such window complies with both of the following:
   2.1. The replacement window meets the size requirements in Item 1.
   2.2. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

Reason: The intent of this proposal is to allow for some existing or replacement windows to be used for emergency escape and rescue openings (EEROs) while still maintaining the level of safety for occupants and emergency responders. EEROs are required in IBC Section 1030 only in R-3 and R-4 dwellings and for R-2 apartments in single exit buildings (4 units per floor, 3 stories maximum). So looking at something converting to a single family home per Table 1011.1, Section 1104.1 would only apply if a house was made out of an F-2, S-2 or U – such as a barn to a house. Any other use being converted to a house would be under Section 1011.4.2 – which has no language for EEROs. There’s does not appear to be any justification for a moving to the same or lesser hazard to be more restrictive than what is allowed for an increased hazard.

The provisions in Section 505 and 702 say they are not applicable to COO, so it should be addressed here for any occupancy that converts to R-3, R-4 and single exit R-2. The size currently permitted under Section 1104.1 Exception 7 for existing window is maintained. The requirements for replacement windows is from current language in 505 and 702.

The same language is proposed for COO under the prescriptive method – which currently does not address EEROs at all.

The IRC requires EEROs in Section R310.1. Current Section R310.5 and R310.6 state when a EERO needs to be added. The exceptions say an existing EERO can be used instead of one added, but it does not have the same allowances for existing windows currently found in the IEBC. It is proposed to allow for this by the new exceptions in R310.5 and 310.6 and a new R301.9.1 which mirrors the current language in the IEBC.
The order of R310.6 of the current allowances has been revised because the exception was more restrictive than the main text.

This is one of a series of proposals to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will decrease the cost of construction
The proposed allowance would allow for existing or replacement windows to be used instead of having to install new in some cases.

Proposal # 5755
2018 International Existing Building Code

Revise as follows:

SECTION 1011
CHANGE OF OCCUPANCY CLASSIFICATION

1011.1 General. The provisions of this section shall apply to buildings or portions thereof undergoing a change of occupancy classification. This includes a change of occupancy classification within a group as well as a change of occupancy classification from one group to a different group where there is a change of occupancy within a space where there is a different fire protection system threshold requirement in Chapter 9 of the International Building Code. Such buildings shall also comply with Sections 1002 through 1010 of this code. The application of requirements for the change of occupancy shall be as set forth in Sections 1011.1 through 1011.4. A change of occupancy, as defined in Section 202, without a corresponding change of occupancy classification shall comply with Section 1001.2.

Delete without substitution:

1011.1.1 Compliance with Chapter 9. The requirements of Chapter 9 shall be applicable throughout the building for the new occupancy classification based on the separation conditions set forth in Sections 1011.1.1.1 and 1011.1.1.2.

1011.1.1.1 Change of occupancy classification without separation. Where a portion of an existing building is changed to a new occupancy classification or where there is a change of occupancy within a space where there is a different fire protection system threshold requirement in Chapter 9 of the International Building Code, and that portion is not separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the International Building Code for the separate occupancy, the entire building shall comply with all of the requirements of Chapter 9 of this code applied throughout the building for the most restrictive occupancy classification in the building and with the requirements of this chapter.

1011.1.1.2 Change of occupancy classification with separation. Where a portion of an existing building is changed to a new occupancy classification or where there is a change of occupancy within a space where there is a different fire protection system threshold requirement in Chapter 9 of the International Building Code, and that portion is separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the International Building Code for the separate occupancy, that portion shall comply with all of the requirements of Chapter 9 of this code for the new occupancy classification and with the requirements of this chapter.

1011.1.2 Fire protection and interior finish. The provisions of Sections 1011.2 and 1011.3 for fire protection and interior finish, respectively, shall apply to all buildings undergoing a change of occupancy classification.

1011.1.3 Change of occupancy classification based on hazard category. The relative degree of hazard between different occupancy classifications shall be determined in accordance with the categories specified in Tables 1011.4, 1011.5 and 1011.6. Such a determination shall be the basis for the application of Sections 1011.4 through 1011.7.

Revise as follows:

1011.2 Fire protection systems. Fire protection systems shall be provided in accordance with Sections 1011.2.1 and 1011.2.2.

1011.2.1 Fire sprinkler system. Where a change in occupancy classification occurs or where there is a change of occupancy within a space where there is a different fire protection system threshold requirement in Chapter 9 of the International Building Code that requires an automatic fire sprinkler system to be provided based on the new occupancy in accordance with Chapter 9 of the International Building Code, such the installation of the automatic sprinkler system shall be provided throughout the area where the change of occupancy occurs, required within the area of the change of occupancy and areas of the building not separated horizontally and vertically from the change of occupancy by one of the following:

1. Non rated permanent partition
2. Fire Partition
3. Smoke Partition
4. Smoke Barrier
5. Fire Barrier
6. Fire wall

Exceptions:

1. An automatic sprinkler system shall not be required in a one or two family dwelling constructed in accordance with the IRC.
2. Automatic sprinkler system shall not be required in a townhouse constructed in accordance with the IRC.
3. The townhouse shall be separated from adjoining units in accordance with Section R302.2 of the International Residential Code.

1011.2.2 Fire alarm and detection system. Where a change in occupancy classification occurs or where there is a change of occupancy within a space where there is a different fire protection system threshold requirement in Chapter 9 of the International Building Code that requires a fire alarm and detection system to be provided based on the new occupancy in accordance with Chapter 9 of the International Building Code, such system shall be provided throughout the area where the change of occupancy occurs. Existing alarm notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm notification appliances shall be provided throughout the area where the change of occupancy occurs in accordance with Section 907 of the International Building Code as required for new construction.

Reason: The point of the revisions to 1011.2.1 is to allow for existing buildings that wish to add a sprinkler system to do so in such a manner that the partial sprinkler system will be within walls so that it will activate appropriately. So, regardless of a work area, the sprinkler system is within a space confined by walls that will allow for the heat to activate the sprinkler system. The end result, while not confined to separated occupancies or fire areas, should get existing buildings sprinklered over time. This would be required even if the area was of a lesser hazard, unlike some of the breaks offered in Sections 1011.4 through 1011.6.

The current language could be read to require the entire fire area or building to be sprinklered, even where only a single tenant is undergoing a change of occupancy. In looking to make the general reference to Chapter 9 in Section 1011.1.1, 1011.1.1.1 and 1011.1.1.2 consistent with the allowances in 1022.2 through 1011.2.2, it seemed more appropriate to delete the language since this will be specifically addressed.

The exceptions to Section 1011.2.1 was for consistency with the allowances for existing building in the IRC. Note that townhouses would be required to be separated.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This would allow sprinkler systems to be added in a building over time rather than throughout where a COO occurs.
1011.2.1.1 Nonrequired automatic sprinkler systems. The code official is authorized to permit the removal of existing automatic sprinkler system where all of the following conditions exist:

1. The system is not required for new construction.
2. The system is removed in its entirety throughout the building.
3. The system was not installed as part of any special construction features, including fire-resistance-rated assemblies and smoke-resistive assemblies, conditions of occupancy, means of egress conditions, fire code deficiencies, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building.

1011.2.1.1.1 Approval. Plans, investigation and evaluation reports, and other data shall be submitted documenting compliance with Items 1 and 2 of Section 1011.2.1.1 for review and approval in support of a determination authorizing the removal of the automatic sprinkler system by the code official.

Reason: A change of occupancy could be to an occupancy that did not require a sprinkler system. If the system was old, outdated or needed extensive reconfiguration, costs could be high. The new Section 1011.2.1.1 allows for non required systems to be removed. To be removed the designer/building owner would have to demonstrate to the code official that the building did not need the sprinklers for occupancy, fire areas or type of construction limitations, and that none of the trade off's for items such as travel distance or corridor rating were in effect in the building. The system would have to be removed totally – including the system in the ceiling, standpipes and the connections for the fire department outside of the building.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There will be the cost of removal, but this may be less than the cost of repairing or replacing an older system.
EB104-19
IEBC®: 1011.7.2 (New), 1011.7.4 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code
Revise as follows:

1011.7.2 Stairways. Where a change of occupancy classification is made to a higher-hazard category as shown in Table 1011.4, interior stairways shall be enclosed as required by the International Building Code.

Exceptions:
1. In other than Group I occupancies, an enclosure shall not be required for openings serving only one adjacent floor and that are not connected with corridors or stairways serving other floors.
2. Unenclosed existing stairways need not be enclosed in a continuous vertical shaft if each story is separated from other stories by 1-hour fire-resistance-rated construction or approved wired glass set in steel frames and all exit corridors are sprinklered. The openings between the corridor and the occupant space shall have not fewer than one sprinkler head above the openings on the tenant side. The sprinkler system shall be permitted to be supplied from the domestic water-supply systems, provided that the system is of adequate pressure, capacity, and sizing for the combined domestic and sprinkler requirements.
3. Existing penetrations of stairway enclosures shall be accepted if they are protected in accordance with the International Building Code. Stairways enclosed in compliance with the applicable provisions of Section 903.1.

1011.7.4 Openings. Openings into existing vertical shaft enclosures shall be protected by fire assemblies having a fire protection rating of not less than 1 hour and shall be maintained self-closing or shall be automatic-closing by actuation of a smoke detector. Other openings shall be fire protected in an approved manner. Existing fusible linktype automatic door-closing devices shall be permitted in all shafts except stairways if the fusible link rating does not exceed 135°F (57°C).

Exception: Existing penetrations of stairway enclosures shall be accepted if they are protected in accordance with the International Building Code.

Reason: This is an editorial correction. Without this exception, the means of egress allowance to use the provisions of Section 903.1 (and 802.2) would not be applicable in change of occupancy classification with alterations projects. This will make the requirements consistent and provide a pointer to 903.1. The exception related to openings (1011.7.2 Exception 3) is moved to Section 1011.7.4 since that deals with openings into exiting vertical shafts.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/odedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The proposal is an editorial correction and may reduce potential costs by providing design options.
2018 International Existing Building Code
Add new text as follows:

1012
STORM SHELTER

1012.1 **Group E occupancy.** In areas where the shelter design wind speed for tornados is 250 mph in accordance with Figure 1304.2(1) of ICC 500, all buildings undergoing a change a occupancy to Group E where the occupant load is 50 or more, shall have a storm shelter constructed in accordance with ICC 500.

**Exceptions:**
1. Group E day care facilities.
2. Group E occupancies accessory to places of religious worship.
3. Buildings meeting the requirements for storm shelter design in ICC 500.

1012.1.1 **Required occupant capacity.** The required occupant capacity of the storm shelter shall include all buildings on the site, and shall be the total occupant load of the classrooms, vocational rooms and offices in the Group E occupancy.

**Exceptions:**
1. Where the change of occupancy to Group E is on an existing Group E site, and where the area of the change of occupancy to Group E is not of sufficient size to accommodate the required occupant capacity of the storm shelter for all of the buildings on-site, the storm shelter shall at a minimum accommodate the required capacity for the area undergoing the change of occupancy to Group E.
2. Where approved by the code official, the required occupant capacity of the shelter shall be permitted to be reduced by the occupant capacity of any existing storm shelters on the site.

**Reason:** The IEBC currently requires tornado shelters for additions in Section 502.8, 1106, 1301.2.3.1. However, Chapter 10, related to change of occupancy, has no provisions requiring tornado shelters for areas changed to Group E occupancy. It is common in many areas of the country for schools to purchase existing buildings that were designed for commercial or public use other than a Group E occupancy so that the school can convert the facilities into a Group E occupancy. This is especially common for smaller private schools however it can also occur in public-private partnerships. If a storm shelter is required for new buildings and for additions, building officials have indicated that this should be required for changes of use to Group E occupancy and have requested this code change to clarify the code intent.

**Cost Impact:** The code change proposal will increase the cost of construction
This would increase the cost of construction by requiring tornado shelters in existing buildings that do not have any Group E occupancies where they are being changed to a Group E occupancy.

Proposal # 5625
EB106-19

EBC: 1104.1, 1105.1

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code
Revise as follows:

SECTION 1104
SMOKE ALARMS IN OCCUPANCYGROUPS R AND I-1

1104.1 Smoke alarms in existing portions of a building. Where an addition is made to a building or structure of a Group R or I-1 occupancy, the existing building shall be provided with smoke alarms as required by Section 1103.8 of the International Fire Code or Section R314 of the International Residential Code as applicable.

SECTION 1105
CARBON MONOXIDE ALARMS IN GROUPS I-1, I-2, I-4 AND R

1105.1 Carbon monoxide alarms in existing portions of a building. Where an addition is made to a building or structure of a Group I-1, I-2, I-4 or R occupancy, the existing building shall be equipped with carbon monoxide alarms in accordance with Section 1103.9 of the International Fire Code or Section R315 of the International Residential Code, as applicable.

Reason: The reference to the IRC for requirements in the existing building, where there is no work (addition) occurring is incorrect and not applicable as there are no IRC requirements for an area that is not undergoing repair, alteration or addition. The change in the IFC reference section is simply to simplify the pointer; IFC Section 1103.9 basically refers to Section 915 with the only technical difference being Exception 1 which states “Carbon monoxide alarms are permitted to be solely battery operated where the code that was in effect at the time of construction did not require carbon monoxide detectors to be provided”; which is an appropriate exception for the retroactive requirements in IFC Chapter 11. If an Addition is being conducted, the carbon monoxide alarm requirements for new construction are appropriate.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction This is providing a more appropriate reference, not a change in requirements.

Proposal # 4308

EB106-19
### 2018 International Existing Building Code

#### SECTION 1106

**STORM SHELTERS**

**1106.1 Addition to a Group E occupancy.** Where an addition is added to an existing Group E occupancy located in an area where the shelter design wind speed for tornados is 250 mph in accordance with Figure 304.2(1) of ICC 500 and the occupant load in the addition is 50 or more, the addition shall have a storm shelter constructed in accordance with ICC 500.

**Exceptions:**

1. Group E day care facilities.
2. Group E occupancies accessory to places of religious worship.
3. Additions meeting the requirements for shelter design in ICC 500.

**Revise as follows:**

**1106.1.1 Required occupant capacity.** The required occupant capacity of the storm shelter shall include all buildings on the site, and shall be the greater of the following:

1. The total occupant load of the classrooms, vocational rooms and offices in the Group E occupancy.
2. The occupant load of any the largest indoor assembly space that is associated with the Group E occupancy.

**Exceptions:**

1. Where an addition is being added on an existing Group E site, and where the addition is not of sufficient size to accommodate the required occupant capacity of the storm shelter for all of the buildings on-site, the storm shelter shall at a minimum accommodate the required capacity for the addition.
2. Where approved by the code official, the required occupant capacity of the shelter shall be permitted to be reduced by the occupant capacity of any existing storm shelters on the site.

**1106.1.2 Location.** Storm shelters shall be located within the buildings they serve, or shall be located where the maximum distance of travel from not fewer than one exterior door of each building to a door of the shelter serving that building does not exceed 1,000 feet (305 m).

**Add new text as follows:**

**1106.1.3 Occupancy classification.** The occupancy classification for storm shelters shall be determined in accordance with Section 423.3 of the International Building Code.

**Reason:** Occupancy classification was added in the IBC Section 423 by G59-18. Since the IEBC uses the IBC for occupancy classifications, it seems appropriate to make this a reference. G65-18 made the clarification in Section 1106.1.1 Item 2 for assembly spaces in Section 423.4.1 Item 2.

This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC 500 Code Development committee.

BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

The ICC 500 Standards Development committee is responsible for the development of the ICC/NSSA Standard for the Design and Construction of Storm Shelters. The committee is currently working on the development of the 2020 edition. In 2017 the ICC 500 committee held 7 open conference calls. In addition, there were numerous Working Group meetings and conference calls, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
This is a coordination with clarifications added to 2021 IBC.
Propoent: Marc Levitan, representing the ICC 500 Storm Shelter Development Committee; Benchmark Harris representing the National Storm Shelter Association (NSSA) (bharris@huckabee-inc.com)

2018 International Existing Building Code

SECTION 1106
STORM SHELTERS

Revise as follows:

1106.1 Addition to a Group E occupancy. Where an addition is added to an existing Group E occupancy located in an area where the shelter design wind speed for tornados is 250 mph in accordance with Figure 304.2(1) of ICC 500 and the occupant load in the addition is 50 or more, the addition shall have a storm shelter constructed in accordance with ICC 500.

Exceptions:

1. Group E day care facilities.
2. Group E occupancies accessory to places of religious worship.
3. Additions meeting the requirements for shelter design in ICC 500.

1106.1.1 Required occupant capacity. The required occupant capacity of the storm shelter shall include all buildings on the site, and shall be the greater of the following:

1. The total occupant load of the classrooms, vocational rooms and offices in the Group E occupancy.
2. The occupant load of any indoor assembly space that is associated with the Group E occupancy.

Exceptions:

1. Where an addition is being added on an existing Group E site, and where the addition is not of sufficient size to accommodate the required occupant capacity of the storm shelter for all of the buildings on-site, the storm shelter shall at a minimum accommodate the required capacity for the addition.
2. Where approved by the code official, the required occupant capacity of the shelter shall be permitted to be reduced by the occupant capacity of any existing storm shelters on the site.

Reason: This proposal is submitted by the National Storm Shelter Association (NSSA) and the ICC 500 Storm Shelter Standard Development committee.

The ICC 500 Standards Development committee is responsible for the development of the ICC/NSSA Standard for the Design and Construction of Storm Shelters. The committee is currently working on the development of the 2020 edition. In 2017 the ICC 500 committee held 7 open conference calls. In addition, there were numerous Working Group meetings and conference calls, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm.

NSSA was responsible for the development of the original standard for storm shelters in 2001, which ICC 500 replaced through an agreement between ICC and NSSA. Representing General, User and Producer interest categories, NSSA is a technical organization that is committed to promoting consistent quality in both residential and community storm shelters.

For the same reason that the code does not require shelters for the entire population that outdoor venues can accommodate, such as outdoor football fields, it should not be necessary for schools to increase the size of the shelters for criteria 2. It is common for schools to share sites with other buildings that have indoor assembly areas that many building officials conservatively consider to be associated with a Group E occupancy. These assembly areas are often on the same site as the school and are sometimes even used by students during the school day, but these assembly areas do not add to the normal population of students in school and the staff that are associated with those students. Many school communities can understand and support the unfunded mandate in tornado prone areas that schools bear the cost of providing tornado shelters for minors that are required by law to be in the care of a school and those adult individuals taking care of them, out of an elevated obligation that comes with having school be mandatory for minors in our country. However, it is inappropriate to require that school systems bear the cost of sheltering possible occupants from the public at these areas. The population for criteria 2 can be significantly larger than criteria 1 when there are large assembly spaces on the site such as a public library (e.g. when a public library operates on a school campus and also functions as the school library), indoor football field, performing arts center, equestrian arena, natatorium, competition basketball arena, and/or professional development center.
The additional people in question (above and beyond criteria 1) elect to be in those assembly areas (as adults, or as minors before or after normal school hours at the permission of their parents/guardians), just like they do in any commercial or other public assembly area. If ICC believed that the public in all assembly areas needed to be sheltered because the tornado hazards are that significant in those areas, then those types of businesses should be required to build tornado shelters too. The current code places an inequitable financial burden on school districts. More importantly, though, the additional area of shelter will most likely never be used.

Yes, if a tornado with windspeeds greater than the main building was designed to withstand happens to occur at the exact moment that there is an assembly with more people than the criteria 1 population, the additional area of the shelter could be used. However, there is a very low probability of this occurring and, other than this occurrence, the additional area of shelter would typically never be used because school districts that are constructing code-required shelters (not FEMA funded safe rooms) typically have no intention of ever opening their tornado shelters up to the general public because of the many operational challenges (e.g. concern with overcrowding above the shelter capacity) and increased liability.

This issue is further complicated by the fact that Section 1106.1.2 requires storm shelters be within 1,000 feet of the buildings they serve. Many high school campuses have buildings with Assembly functions (that building officials conservatively consider to be associated with an E occupancy) greater than 1,000 feet from the school building. The code is not clear whether these assembly areas require their own tornado shelter. Removing criteria 2 would resolve this dilemma by clearly identifying that the occupant load of the classrooms, vocational areas and offices are the areas that need to be served with tornado shelters.

The rationale to remove criteria 2 applies to new campuses as well as existing construction; however, it is especially applicable for additions to existing campuses where options to provide a tornado shelter are much more limited because the existing buildings were not designed with a future tornado shelter in mind.

The following is an example based on a real case provided by a school district in Texas, with some modifications made to simplify the example:

There is an existing academy and an existing performing arts center on a 100 Acre site, with the two buildings more than 1,000 feet apart, and the 2018 IEBC is in effect. The school system proposed an addition to the existing academy to double the criteria 1 population from 1,000 to 2,000. The criteria 1 population of the performing arts center is 0. The Building Official considers the performing arts center to be an A that is associated with an E occupancy. There are moveable partitions in the performing arts center that allow all of the rooms (except for the lobby) to open up into one large performing arena for 5,000 people in seats and up to 500 people on stage, making the criteria 2 population (the largest indoor assembly area associated with the E occupancy on the site) 5,500 people. The school system is required to build a shelter for at least 5,500 people because the floor plan area of the proposed addition to the academy could accommodate 5,500 people if the entire addition was one large tornado shelter. If the two buildings were closer than 1,000 feet, the 2018 IEBC would require $10 Million of sheltering ($5.6 Million for the 2,000 people in a multi-purpose shelter and $4.4 Million for 3,500 people in a dedicated, single-use shelter). This means that even in the 1,000 feet proximity rule was not in effect, this school system would need to spend $4.4 Million on sheltering the additional population that could be in a performing arts center. However, because the buildings are more than 1,000 feet apart, the actual cost impact of criteria 2 is much greater at this campus because 2 separate shelters are required to accommodate the travel distance requirement. 2018 IEBC section 1106.1.2 requires that the shelters be located within 1,000 feet of the “population they serve” and these two buildings are more than 1,000 feet apart. Therefore, the code requires that a 5,500 person shelter be constructed as a new addition to the performing arts center to accommodate that population and a 2,000 person shelter be constructed as part of the proposed addition to the academy. The combined cost of these two shelters would be $12.5 Million ($5.6 Million for the 2,000 people in the multi-purpose shelter by the academy and $6.9 Million for 5,500 people in a dedicated, single-use shelter by the performing arts center). The school system was prepared to construct a $5.6 Million shelter for the 2,000 people in the multi-purpose shelter by the academy but could not fund the additional $6.9 Million (associated with the criteria 2 requirement) to shelter the performing arts center population, which is a special events center. Therefore, the school system was not able to double the population of their academy as they had hoped.

**Cost Impact:** The code change proposal will decrease the cost of construction

There will be a decrease in the cost for storm shelters for existing schools that have associated assembly spaces larger than the student population.
2018 International Existing Building Code

Delete without substitution:

1106.1.2 Location. Storm shelters shall be located within the buildings they serve, or shall be located where the maximum distance of travel from not fewer than one exterior door of each building to a door of the shelter serving that building does not exceed 1,000 feet (305 m).

Reason: While 1,000 feet maximum travel may be appropriate for new schools, this can be an undue hardship for existing buildings. Where an addition is located may be limited by a variety of building and site constraints.

And, good management of a storm shelter is often better when there is 1 location instead of many smaller tornado shelters. For example, it’s possible to overcrowd a tornado shelter when there are multiple shelters onsite and it is not clear which shelter has room available, unless all tornado shelters are designed to accommodate the entire population of the campus which would be a significant, redundant cost. Furthermore, emergency rescue is greatly assisted when there are a fewer number of tornado shelters for people to be rescued from.

An example of how the current provision can create a significant and unnecessary financial impact at a campus: A large, existing community college in Texas with 25 buildings throughout an approximately 200 Acre campus. 1 building in the middle of the campus is for high school students that want to earn early college credit, making this existing building a Group E building. The other 24 buildings have assembly spaces that are considered an accessory to the Group E occupancy because they can be used by the high school students. The campus wants to build a large addition to the early college learning building for high school students, one that is large enough to accommodate the population required by Section 1106.1.1. However, there are indoor assembly spaces that are spread throughout the entire campus, much greater than 1,000 feet, requiring that multiple new tornado shelters be constructed for the assembly spaces that are accessory to a Group E occupancy. Tornado Shelters are not required for college campus classrooms, which are Group B. It is an unnecessary burden to require a community college campus construct multiple tornado shelters throughout their campuses when there are emergency planning alternatives. The community college can manage the high school student population by directing those students to their designated shelters at early signs of an approaching storm, even though some students may be in a building farther than 1,000 feet from the shelter when a tornado approaches.

Cost Impact: The code change proposal will decrease the cost of construction
Decrease. Removing the requirement for a maximum 1,000 foot travel distance avoids constructing multiple tornado shelters at large campuses, instead of one.
Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

1201.3 Special occupancy exceptions—museums. Where a building in Group R-3 is used for Group A, B or M purposes such as museum tours, exhibits, and other public assembly activities, or for museums less than 3,000 square feet (279 m²), the code official may be authorized to determine that the occupancy is Group B where life safety conditions can be demonstrated in accordance with Section 1201.2. Adequate means of egress in such buildings, which may include, but are not limited to, a means of maintaining doors in an open position to permit egress, a limit on building occupancy to an occupant load permitted by the means of egress capacity, a limit on occupancy of certain areas or floors, or supervision by a person knowledgeable in the emergency exiting procedures, shall be provided.

Reason: This addresses non mandatory language.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Editorial.

Proposal # 4222
2018 International Existing Building Code

Revise as follows:

1203.3 Means of egress. Existing door openings and corridor and stairway widths less than those specified elsewhere in this code may be approved, provided that, Where, in the opinion of the code official, there is sufficient width and height for a person to pass through the opening or traverse the means of egress, existing door openings and corridor and stairway widths not required to meet the widths required by the International Building Code or this code. Where approved by the code official, the front or main exit doors need not swing in the direction of the path of exit travel, provided that other approved means of egress having sufficient capacity to serve the total occupant load are provided.

Reason: This addresses non mandatory language and also addresses the fact that this is likely intending to refer also to the IBC. This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This is editorial.
2018 International Existing Building Code

Revise as follows:

1204.9 Finishes. Interior finish materials are required to have a flame spread index of Class C or better, when tested in accordance with ASTM E84 or UL 723 comply with the fire test requirements of Section 803.1 of the International Building Code, existing nonconforming materials shall be permitted to be surfaced with an approved fire-retardant paint or finish coating to achieve the required fire performance.

Exception: Existing nonconforming materials need not be surfaced with an approved fire-retardant paint or finish coating where the building is equipped throughout with an automatic sprinkler system installed in accordance with the International Building Code and the nonconforming materials can be substantiated as being historic in character.

Reason: This code proposal makes two changes:
1. Neither the IBC nor the IFC allow all interior finish materials to be tested to ASTM E84 or UL 723. In fact, although all materials are allowed to be classified by NFPA 286 (a room corner test), some materials are not allowed to be classified by using ASTM E84 or UL 723. Any material that meets the requirements of the IBC code (or IFC code) based on testing to NFPA 286 is considered to comply with a Class A, Class B or Class C requirement, in accordance with ASTM E84 or UL 723. Therefore it is possible that interior finish materials have been shown to meet NFPA 286 requirements and they are (in accordance with the IBC) acceptable as materials with a “Class C or better” in accordance with ASTM E84 or UL 723 and don’t need retesting (or may not even be allowed by the IBC to be tested to ASTM E84 or UL 723). The use of a reference exclusively to a Class C, without a reference to the IBC or IFC, prevents the use of materials tested to (or needing testing to) NFPA 286.

2. The typical nomenclature used in the IBC and IFC is fire-retardant coating.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The revision simply permits materials already tested to NFPA 286 to be covered.
2018 International Existing Building Code

Revise as follows:

1204.9 Finishes. Where interior finish materials are required to have a flame spread index of Class C or better, when tested in accordance with ASTM E84 or UL 723, existing nonconforming materials shall be surfaced with an approved fire-retardant paint or finish, fire-retardant coating. Compliance with this section shall be demonstrated by testing the fire-retardant coating on the same material and achieving the required performance. If the same material is not available, it shall be permitted to test on a similar material.

Exception: Existing nonconforming materials need not be surfaced with an approved fire-retardant paint or finish coating where the building is equipped throughout with an automatic sprinkler system installed in accordance with the International Building Code and the nonconforming materials can be substantiated as being historic in character.

Reason: It is important to clarify that, if fire retardant coatings are to be used to achieve improved fire performance, they must have been tested on the actual product (substrate) to which they will be applied. There have been instances of manufacturers applying coatings to a noncombustible surface and running an ASTM E84 test in an attempt to demonstrate compliance. (See figures below). This obviously does not reflect real world performance and is not the intent of the code. This proposal would make the requirement more explicit.

This proposal also replaces “paint or finish” with the more generic term “coating” which is used throughout the I-codes.
Cost Impact: The code change proposal will increase the cost of construction
This may increase the cost of construction by requiring tests to be run on the surface intended to be used.
Proponent: Kevin Duerr-Clark, representing NYS Department of State (kevin.duerr-clark@dos.ny.gov)

2018 International Existing Building Code

Revise as follows:

1301.2 Applicability. Existing buildings in which there is work involving additions, alterations or changes of occupancy shall be made to conform to the requirements of this chapter or the provisions of Chapters 6 through 10. The provisions of Sections 1301.2.1 through 1301.2.5 shall apply to existing occupancies that will continue to be, or are proposed to be, in Groups A, B, E, F, I-2, M, R and S. These provisions shall apply to Group U occupancies only where such occupancies are undergoing a change of occupancy or a partial change in occupancy with separations in accordance with Section 1301.2.2. These provisions shall not apply to buildings with occupancies in Group H, I-1, I-3, or I-4.

Reason: Currently, the applicability section is silent on the use of this section on Group U buildings. Although Section 1301.6 Evaluation process, clearly allows it for Group U buildings, the intent is the allows the use of this compliance method for changing from one Group U to another Group. Group U buildings undergoing alterations or additions with no change in occupancy cannot be evaluated using this method. The tables, charts, and point system do not accommodate this. This proposal simply clarifies the proper use of this method for Group U buildings.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is a clarification of how the code is already used.
2018 International Existing Building Code

Revise as follows:

1301.1 Scope. The provisions of this chapter shall apply to the alteration, addition and change of occupancy of existing structures, including historic structures, as referenced in Section 301.3.3. The provisions of this chapter are intended to maintain or increase the current degree of public safety, health and general welfare in existing buildings while permitting, alteration, addition and change of occupancy without requiring full compliance with the prescriptive method of Chapter 5 or the work area method of Chapters 6 through 12, except where compliance with other provisions of this code is specifically required in this chapter.

Reason: This compliance method should not require compliance with both the prescriptive and work area methods. As currently written, because only Chapters 6 through 12 are listed, it could be construed that compliance with Chapter 5, Prescriptive Compliance Method is required. By adding the Chapter 5 reference, it clarifies the intent to absolve projects that are properly design in accordance with Chapter 13 from compliance with both the Prescriptive and Work Area methods.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This is merely further clarification that this method would not require further compliance with the prescriptive method, if compliance with the performance method is established.
Proponent: Kevin Duerr-Clark, representing NYS Department of State (kevin.duerr-clark@dos.ny.gov); Erika Krieger, representing NYS Department of State (codeczar@optonline.net)

2018 International Existing Building Code

Revise as follows:

1301.2 Applicability. Existing buildings in which there is work involving additions, alterations or changes of occupancy shall be made to conform to the requirements of this chapter or the provisions of Chapters 6 through 10. The provisions of Sections 1301.2.1 through 1301.2.5 shall apply to existing occupancies that will continue to be, or are proposed to be, in Groups A, B, E, F, I-2, M, R and S. These provisions shall not apply to buildings with occupancies in Group H or I-1, I-3 or I-4.

Add new text as follows:

1301.2.6 Plumbing Fixtures. Plumbing fixtures shall be provided in accordance with Section 1009 for a Change of Occupancy and Section 809 for Alterations. Plumbing fixtures for additions shall be in accordance with the International Plumbing Code.

Reason: Currently there does not appear to be a code path, within the performance compliance method, to require additional plumbing facilities or fixtures for buildings undergoing alterations, additions, and changes in occupancy, where the occupant load is increased. The performance compliance method focuses primarily on fire and life safety. Historically, applicants have argued that due to the lacking code path, they can increase the occupant load of a building and achieve compliance using the performance method, without increasing the number of plumbing fixtures or facilities to account for the increased occupant load. This new language would provide a code path to specifically require fixtures and facilities yet provides the same level of leniency as the other compliance paths available in the Existing Building Code.

Cost Impact: The code change proposal will increase the cost of construction. This may increase the cost of construction because today, the code path to require the additional facilities does not exist.
Proponent: Gregory Nicholls, representing American Institute of Architects (gnicholls@preview-group.com)

2018 International Existing Building Code

Revise as follows:

1301.2.2 Partial change in occupancy. Where a portion of the building is changed to a new occupancy classification and that portion is separated from the remainder of the building with fire barrier or horizontal assemblies having a fire-resistance rating as required by Table 508.4 of the International Building Code or Section R302 of the International Residential Code for the separate occupancies, or with approved compliance alternatives, the portion changed shall be made to conform to the provisions of this section. Only the portion separated shall be required to be evaluated for compliance.

Where a portion of the building is changed to a new occupancy classification and that portion is not separated from the remainder of the building with fire barriers or horizontal assemblies having a fire-resistance rating as required by Table 508.4 of the International Building Code or Section R302 of the International Residential Code for the separate occupancies, or with approved compliance alternatives, the provisions of this section which apply to each occupancy shall apply to the entire building. Where there are conflicting provisions, those requirements which secure the greater public safety shall apply to the entire building or structure.

Reason: The code text does not explain how to evaluate a separated partial change of occupancy. The current ICC code commentary is not at all consistent with how a partial change of occupancy is treated in Section 1011.1.1.2 IEBC, even though the wording is almost the same. The code text and commentary for Section 1011.1.1.2 IEBC specifically only require compliance with Chapter 9 IEBC for that portion within the fire-resistance rated separations. When using the Performance Compliance Method in Section 1301 IEBC, once again the code text only dictates that the portion changed and separated has to comply. But that leaves some confusion as to how the evaluation needs to be done, and this is apparent with the over-reaching interpretation in the IEBC commentary, which reads,

“Where a portion of the building is changed to a new occupancy classification and that portion is separated from the remainder of the building by a fire barrier that complies with the requirements for new construction, the new occupancy portion must be evaluated with the existing or proposed building design to be in full compliance with the provisions of Chapter 13. The remainder of the existing building must also be evaluated in accordance with Chapter 13. The mandatory safety scores for the new occupancy portion of the building and the existing occupancy are obtained from those listed in Table 1401.8 and are incorporated in the building’s final evaluation score (see Table 1401.7).”

The requirement stated in the commentary to evaluate the remainder of the building is in contrast to the code text, and opposite of the code text and intent for partial change of occupancy without the performance compliance method. Why should a fully separated partial change of occupancy on the first floor of a 20-story building need the other stories to comply with the mandatory safety scores when no change of occupancy or alterations are proposed? So if the existing floors above are over the allowable height in current code, then what? This interpretation, which has no support in code text, will make it unfeasible for small changes in occupancy in existing non-compliant buildings.

By adding the text shown, it is then clear that only the portion separated needs to comply and that this is the only portion that needs to be evaluated. This is also making application of the evaluation clear and consistent with Section 1301.2.2 IEBC.

Cost Impact: The code change proposal will decrease the cost of construction

By clarifying the code text to meet the intent of how a partial change in occupancy is limited in scope, the cost of construction to the remainder of the building is reduced.
IEBC®: 1301.3

Proponent: Jeffrey Harper, JENSEN HUGHES, representing JENSEN HUGHES (jharper@jensenhughes.com); Sean Donohue, representing JENSEN HUGHES (sdonohue@jensenhughes.com)

2018 International Existing Building Code

Revise as follows:

1301.3 Acceptance. For repairs, alterations, additions, and changes of occupancy to existing buildings that are evaluated in accordance with this section, compliance with this section shall be accepted by the code official. Existing buildings without repairs, alterations, additions or a change of occupancy that are evaluated and receive a passing score in accordance with Table 1301.8 shall be deemed to comply with Chapter 11 of the International Fire Code.

Reason: Chapter 11 of the IFC provides no alternate to compliance for existing buildings in the same manner that NFPA 101A provides for existing buildings regulated by NFPA 101. The IEBC only applies to buildings undergoing repair, alteration, change of occupancy, addition and relocation of existing buildings. However, Chapter 13 of IEBC allows the performance compliance method to be used for existing occupancies. Per 1301.2: “The provisions of Sections 1301.2 through 1301.5 shall apply to existing occupancies that will continue to be, or are proposed to be in Groups A, B, E, F, I-2, M, R and S.” Therefore, no change is needed to allow the use of this Chapter to existing buildings.

By adding an applicability section to the administrative provisions of the fire code (included in a separate Proposal), the user is given a code path to use the evaluation methods prescribed in Chapter 13 of the IEBC for existing buildings.

Therefore, the change to Section 1301.3 of the IEBC is necessary to add authority for acceptance of the performance compliance method on existing buildings wherein no work is planned. Currently this acceptance section only applies to buildings undergoing construction.

For example: An existing office building’s highest story is 55 feet above the lowest level of fire department access and has been cited for not having any standpipes. Per IFC Section 1103.6, standpipes are required. The building is fully sprinkler protected per NFPA 13 and provided with a fire alarm system throughout. All shafts are 2-hour rated and corridors are 1-hour rated. Egress capacity, travel distances and common paths all exceed that required by the IBC for new construction and elevators have been recently replaced with fully compliant Stage 2 recall capability. The fire code would require standpipes regardless of these other systems. The Performance Compliance Method permits an accepted method of evaluating all components of a building and providing a score to account for deficiencies.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code provision will not increase cost and has a high likelihood of reducing cost by providing flexibility that does not currently exist in the code.
2018 International Existing Building Code
Revise as follows:

1301.6.2 Building area. The value for building area shall be determined by the formula in Section 1301.6.2.2. Section 506 of the International Building Code and the formula in Section 1301.6.2.1 shall be used to determine the allowable area of the building. Subtract the actual building area from the allowable area and divide by 1,200 square feet (112 m²). Enter the area value and its sign (positive or negative) in Table 1301.7 under Safety Parameter 1301.6.2, Building Area, for fire safety, means of egress and general safety. In determining the area value, the maximum permitted positive value for area is 50 percent of the fire safety score as listed in Table 1301.8, Mandatory Safety Scores. Group I-2 occupancies shall be scored zero.

1301.6.2.1 Allowable area formula. The following formula shall be used in computing allowable area:

\[ A_a = A_t + (NS \times I) \]  
(Equation 13-3)

where:

- \( A_a \) = Allowable building area per story (square feet).
- \( A_t \) = Tabular allowable area factor (NS, S1, S13R, or SM value, as applicable) in accordance with Table 506.2 of the International Building Code.
- \( NS \) = Tabular allowable area factor in accordance with Table 506.2 of the International Building Code for a nonsprinklered building (regardless of whether the building is sprinklered).
- \( I \) = Area factor increase due to frontage as calculated in accordance with Section 506.3 of the International Building Code.

1301.6.2.2 Area formula. The following formula shall be used in computing the area value. Determine Equation 13-4 shall be used for a single occupancy buildings and Equation 13-5 shall be used for multiple occupancy buildings. Determine the area value for each occupancy floor area on a floor-by-floor basis. For each multiple occupancy buildings, choose the minimum area value of the set of values obtained for the particular occupancy shall be used as the area value for that occupancy.

For single occupancy buildings:

Area value = \( \frac{A_a - A_r}{1200} \) square feet (Equation 13-4)

For multiple occupancy buildings:

\[ \text{Area value} = \frac{\text{Allowable area} \_i}{1200\text{square feet}} \left[ 1 - \left( \frac{\text{Actual area} \_i}{\text{Allowable area} \_i} \right) \right] \]  
(Equation 13-4)

where:

- \( i \) = Value for an individual separated occupancy on a floor.
- \( n \) = Number of separated occupancies on a floor.

Reason: This section as written is confusing and does not differentiate well between single occupancy buildings and multiple occupancy buildings. This proposal creates two equations to address this. 

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposed code change is clarification of existing code language and neither adds to or decreases cost of construction.
2018 International Existing Building Code

Revise as follows:

1301.6.3 Compartmentation. Evaluate the compartments created by fire barriers or horizontal assemblies which comply with Sections 1301.6.3.1 and 1301.6.3.2 and which are exclusive of the wall elements considered under Sections 1301.6.4 and 1301.6.5. Conforming compartments shall be figured as the net area and do not include shafts, chases, stairways, walls, or columns. Using Table 1301.6.3, determine the appropriate compartmentation value (CV) and enter that value into Table 1301.7 under Safety Parameter 1301.6.3, Compartmentation, for fire safety, means of egress, and general safety.

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>Compartment size equal to or greater than 15,000 square feet</td>
</tr>
<tr>
<td>A-1, A-3</td>
<td>0</td>
</tr>
<tr>
<td>A-2</td>
<td>0</td>
</tr>
<tr>
<td>A-4, B, E, S-2</td>
<td>0</td>
</tr>
<tr>
<td>F, M, R, S-1</td>
<td>0</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.0929 m².

a. For compartment sizes between categories, the compartmentation value shall be obtained by linear interpolation.

Add new text as follows:

1301.6.3.1 Categories. The categories for compartment separations are:

1. Category a—compartment size of 15,000 square feet or more.
2. Category b—maximum compartment size of 10,000 square feet.
3. Category c—maximum compartment size of 7,500 square feet.
4. Category d—maximum compartment size of 5,000 square feet.
5. Category e—maximum compartment size of 2,500 square feet.

Revise as follows:

1301.6.3.1 1301.6.3.2 Wall construction. A wall used to create separate compartments shall be a fire barrier conforming to Section 707 of the International Building Code with a fire-resistance rating of not less than 2 hours. Where the building is not divided into more than one compartment, the compartment size shall be taken as the total floor area on all floors. Where there is more than one compartment within a story, each compartmented area on such story shall be provided with a horizontal exit conforming to Section 1026 of the International Building Code. The fire door serving as the horizontal exit between compartments shall be so installed, fitted, and gasketed that such fire door will provide a substantial barrier to the passage of smoke.

1301.6.3.2 1301.6.3.3 Floor/ceiling construction. A floor/ceiling assembly used to create compartments shall conform to Section 711 of the International Building Code and shall have a fire-resistance rating of not less than 2 hours.

Reason: This proposal is designed to correct an inconsistency in Table 1301.6.3. Currently, there is a hole in the size values for compartment size. There is no recognition of a fire compartment that is between 10,000 and 15,000 square feet.

1. Category a applies to 15,000 sq. ft. or larger

2. Category b applies to 10,000 sq. ft. or less
So what value is applied when the fire compartment is 12,000 square feet. It is not listed on the table and there is no guidance as to the value associated to this size. Obviously, it is better than 15,000 square feet, but is it the same value as 10,000 square feet.

Therefore, this proposal makes two revisions:

1. Moves the criteria out of the table header
2. Corrects the gap in compartment sizes

Moving the criteria out of the table header is an editorial change. But it is consistent with the format used in all the other tables in Chapter 13. It also allows for easier application and use of the table.

The gap between 10,000 and 15,000 square feet is resolved by adding Footnote a. Footnote a allows interpolation between categories. For example, consider a Group B occupancy with the largest compartment of 13,000 square feet. It does not fit into a category, it is between Category a – 15,000 square feet or more, and Category b – 10,000 square feet or less. The score for Category a is “0” and the score for Category b is “5”. By interpolation, the Group B compartment at 13,000 square feet receives a score of “2”. See the table below.

**Cost Impact:** The code change proposal will decrease the cost of construction
This revision allows credit for compartment size between 10,000 and 15,000 square feet where no credit was giving previously.

Proposal # 1486

EB120-19
EB121-19
IEBC: TABLE 1301.6.3

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

1301.6.3 Compartmentation. Evaluate the compartments created by fire barriers or horizontal assemblies which comply with Sections 1301.6.3.1 and 1301.6.3.2 and which are exclusive of the wall elements considered under Sections 1301.6.4 and 1301.6.5. Conforming compartments shall be figured as the net area and do not include shafts, chases, stairways, walls, or columns. Using Table 1301.6.3, determine the appropriate compartmentation value (CV) and enter that value into Table 1301.7 under Safety Parameter 1301.6.3, Compartmentation, for fire safety, means of egress, and general safety.

Revise as follows:

TABLE 1301.6.3
COMPARTMENTATION VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES a</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a</td>
</tr>
<tr>
<td>A-1, A-3</td>
<td>0</td>
</tr>
<tr>
<td>A-2</td>
<td>0</td>
</tr>
<tr>
<td>A-4, B, E, S-2</td>
<td>0</td>
</tr>
<tr>
<td>F, M, R, S-1</td>
<td>0</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.0929 m².

a. For areas between categories, the determination of the compartmentation value obtained by linear interpolation shall be permitted.

Reason: This table when placed in the IEBC never carried over the footnote a that was found in the same table in the IBC Chapter 34. This question arises and this appears within the intent to allow interpolation.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposed change is a coordination item between the IEBC and the IBC and neither adds to or decreases cost of construction.

Proposal # 4226

EB121-19
IEBC®: TABLE 1301.6.3

Proponent: Jeffrey Harper, JENSEN HUGHES, representing JENSEN HUGHES (jharper@jensenhughes.com); Sean Donohue, representing JENSEN HUGHES (sdonohue@jensenhughes.com)

2018 International Existing Building Code
Revise as follows:

**TABLE 1301.6.3**
**COMPARTMENTATION VALUES**

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>aCompartment size equalto or greater than 15,000 square feet</th>
<th>bCompartment size of10,000 square feet</th>
<th>cCompartment size of7,500 square feet</th>
<th>dCompartment size of5,000 square feet</th>
<th>eCompartment size of2,500 square feet or less</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-1, A-3</td>
<td>0</td>
<td>6</td>
<td>10</td>
<td>14</td>
<td>18</td>
</tr>
<tr>
<td>A-2</td>
<td>0</td>
<td>4</td>
<td>10</td>
<td>14</td>
<td>18</td>

<tr>
<td>A-4, B, E, S-2</td>
<td>0</td>
<td>5</td>
<td>10</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>F, M, R, S-1</td>
<td>0</td>
<td>4</td>
<td>10</td>
<td>16</td>
<td>22</td>
</tr>
<tr>
<td>I-2</td>
<td>0</td>
<td>2</td>
<td>8</td>
<td>10</td>
<td>14</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.0929 m².

**Reason:** This table does not provide Group I-2 occupancies with any benefit of fire compartmentation. This should not be confused with 1301.6.20 which provides for smoke zones because 1301.6.3.1 clearly indicates the compartmentation is to be defined based on the use or presence of fire barriers having a fire rating of 2-hours or more. I-2 occupancy should be included on this table to remain consistent with the rest of the Performance Compliance Methods sections. Just as in 1301.6.20, I-2 occupancies on this table should be scored at zero for compartments that comply with 22,500 square feet. Although the code has gone to 40,000 SF compartment sizes for hospitals, this recognizes that nursing homes (I-2 Condition 1) are still at 22,500. There should not be a negative value for being larger than 22,500 SF because this is fire compartmentation, not smoke compartmentation.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code provision will not increase cost and has a high likelihood of reducing cost by providing flexibility that does not currently exist in the code.
IEBC®: TABLE 1301.6.3

Proponent: Kevin Duerr-Clark, NYS Department of State, representing NYS Department of State (kevin.duerr-clark@dos.ny.gov); Ronald Stark, NYS Department of State, representing NYS Department of State (ronald.stark@dos.ny.gov)

2018 International Existing Building Code
Revise as follows:

TABLE 1301.6.3
COMPARTMENTATION VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-1, A-3</td>
<td>0</td>
</tr>
<tr>
<td>A-2</td>
<td>0</td>
</tr>
<tr>
<td>A-4, B, E, S-2</td>
<td>0</td>
</tr>
<tr>
<td>F, M, R, S-1</td>
<td>0</td>
</tr>
</tbody>
</table>

For compartment sizes between categories, values shall be obtained by linear interpolation.

Reason: The compartment sizes given in Table 1301.6.3 are neither consecutive, not all inclusive. The table does not provide guidance for compartment sizes outside of the values given. This leads some applicants to advocate for the higher value and some code officials to argue in favor of the more restrictive lower values. In some instances, the value increase is as high as 6 points, which could make a considerable difference in the Summary Sheet results of Table 1301.7.

To resolve this discrepancy and ensure uniform enforcement, Table 1301.6.3 should include a footnote similar to those found in Tables 1301.6.12 and 1301.6.16, indicating that values between categories shall be obtained by linear interpolation.

The IEBC Commentary states that “the evaluation of the compartments contained in an existing building is a linear function allowing interpolation between the various categories. This approach allows the compartmentation value to increase or decrease consistent with the actual changes in compartment sizes.” However, the language of neither Section 1301.6.3, nor Table 1301.6.3 reflects this intent and therefore, a footnote is needed to remove the ambiguity and facilitate enforcement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal is to provide clarification consistent with the IEBC Commentary and does not have a cost implication.

For SI: 1 square foot = 0.0929 m².

Proposal # 4337
EB124-19

IEBC®: 1301.6.4

Proponent: Gregory Nicholls, representing American Institute of Architects (gnicholls@preview-group.com)

2018 International Existing Building Code

Revise as follows:

1301.6.4 Tenant and dwelling unit separations. Evaluate the fire-resistance rating of floors and walls separating tenants, including dwelling units, and not evaluated under Sections 1301.6.3 and 1301.6.5. Group I-2 occupancies shall evaluate the rating of the separations between patient sleeping rooms.

Under the categories and occupancies in Table 1301.6.4, determine the appropriate value and enter that value in Table 1301.7 under Safety Parameter 1301.6.4, Tenant and Dwelling Unit Separation, for fire safety, means of egress, and general safety. The value shall be zero for single tenant buildings, and buildings without dwelling units.

Reason: The current code text gives no direction on what the appropriate scoring category is for non-residential, single tenant buildings. Since the categories only have partition ratings, the default would penalize the building scores without any justification that having a single tenant is less safe. The added text gives an appropriate score of zero, which does not penalize the building but also does not give points to achieve a passing score.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The code change clarifies the disposition of buildings without dwelling units or multiple tenants. There is no current cost to modify.

Proposal # 5292
Proponent: Gregory Nicholls, representing American Institute of Architects (gnicholls@preview-group.com)

2018 International Existing Building Code

Revise as follows:

1301.6.5.1 Categories. The categories for corridor walls are:

1. Category a—No fire partitions; incomplete fire partitions; no doors; or doors not self-closing.
2. Category b—Less than 1-hour fire-resistance rating or not constructed in accordance with Section 708.4 of the International Building Code.
3. Category c—1-hour to less than 2-hour fire-resistance rating, with doors conforming to Section 716 of the International Building Code or without corridors as permitted by Section 1020 of the International Building Code. Code to be without a fire-resistance rating.
4. Category d—2-hour or greater fire-resistance rating, with doors conforming to Section 716 of the International Building Code.

Reason: The IBC does not require corridors for any project, it only has criteria for corridors when they are proposed. As written, the current code text makes no sense, and nowhere in Section 1020 IBC does it say where corridors are permitted. Further, the current text does not say what to do when a corridor does not have to have a rating, leading to some interpretations that ALL projects using the Performance Compliance method have to have corridors, no matter the occupancy or occupant load.

This appears to be the result of a historical error in editing, one that occurred without a code change, done by ICC staff. Back in the 1995 Basic Building Code (BOCA), the code section for corridors, category c used to read:

Fire partitions having a fireresistance rating from 1 hour to less than 2 hours, with doors conforming to Section 1011.4.2 or without corridors as required by Section 1011.4. Section 1011.4 OBC (1995) was entitled “Enclosure” and only addressed corridors if they were provided (and that was when section titles sort of meant something). When this was transferred to the IBC, the code section on enclosure was no longer worded the same, and was changed to “Construction”. Along with this change in section title the reference from Chapter 34 was to the entire Section on corridors, so the distinction between corridors permitted without a fire-resistance rating went to without corridors.

Compliance Alternatives are not meant to do either of two things:

1. To require corridors in order to comply with one of the categories, even when none are proposed;
2. To require corridors allowed to be non-fire-resistance rated by Section 1020 to have to be 1 hour rated to keep from being severely punished by negative points.

It should be noted that the scoring for all occupancies in category c is zero except for I-2, which is typical in the 3412 scoring system for meeting code for non-3412 projects but not exceeding standard code. In other words, a score of zero does not mean the level of performance is penalized, but without a positive score will not provide any points to pass.

Cost Impact: The code change proposal will decrease the cost of construction
By allowing buildings to not have corridors, and allowing the option to comply without negative points will decrease the cost of compliance.
Proponent: Kevin Duerr-Clark, representing NYS Department of State (kevin.duerr-clark@dos.ny.gov); Erika Krieger, NYS Department of State, representing NYS Department of State (codeczar@optonline.net)

2018 International Existing Building Code

Revise as follows:

1301.6.7.1 Categories. The categories for HVAC systems are:

1. Category a—Plenums not in accordance with Section 602 of the International Mechanical Code. -10 points.
2. Category b—Air movement in egress elements not in accordance with Section 1020.5 of the International Building Code. -5 points.
3. Category c—Both Categories a and b are applicable. -15 points.
4. Category d—Compliance of the HVAC system with Section 1020.5 of the International Building Code and Section 602 of the International Mechanical Code; or where HVAC systems do not contain ductwork. 0 points.
5. Category e—Systems serving one story; or a central boiler/chiller system without ductwork connecting two or more stories. +5 points.

Reason: The stated intent of Section 1301.6.7 is to “evaluate the ability of the HVAC system to resist the movement of smoke and fire.” Points are awarded to systems with a limited ability to spread smoke and fire, such as systems serving only one story. However, the code is silent regarding instances where heating and air conditioning systems utilizing ductwork are not proposed, thus eliminating the risk of spreading smoke and fire. The silence leads to confusion and disagreement among code users on whether to interpret that those instances constitute a category "d" or a category "e".

Without heating and air conditioning ductwork, the degree of code compliance and fire safety is equal to or greater than category "e" and points should be gained. That change in code language is proposed under the title “HVAC System Categories I.” However, should that previous proposal not be approved, the code language should at least mention the lack of ductwork as a condition in category “d” and eliminate the ambiguity.

Cost Impact: The code change proposal will increase the cost of construction

This change addresses a silent provision in the code. There is no change if the provision was previously interpreted to constitute category "d".
There is a small likelihood that it could increase the cost of construction if code users had interpreted the silent provision to constitute category "e".
IEBC®: 1301.6.7.1

Proponent: Kevin Duerr-Clark, NYS Department of State, representing NYS Department of State (kevin.duerr-clark@dos.ny.gov); Erika Krieger, NYS Department of State, representing NYS Department of State (codeczar@optonline.net)

2018 International Existing Building Code

Revise as follows:

1301.6.7.1 Categories. The categories for HVAC systems are:

1. Category a—Plenums not in accordance with Section 602 of the International Mechanical Code. -10 points.
2. Category b—Air movement in egress elements not in accordance with Section 1020.5 of the International Building Code. -5 points.
3. Category c—Both Categories a and b are applicable. -15 points.
4. Category d—Compliance of the HVAC system with Section 1020.5 of the International Building Code and Section 602 of the International Mechanical Code. 0 points.
5. Category e—Systems serving one story; or a central boiler/chiller system without ductwork connecting two or more stories— OR where systems have no ductwork. +5 points.

Reason: The stated intent of Section 1301.6.7 is to “evaluate the ability of the HVAC system to resist the movement of smoke and fire.” Points are awarded to systems with a limited ability to spread smoke and fire, such as systems serving only one story. The code is silent regarding instances where the heating and air conditioning systems do not utilize ductwork, thus eliminating the risk of spreading smoke and fire. Without heating and air conditioning ductwork, the degree of code compliance and fire safety is equal or greater than category “e” and points should be gained.

Cost Impact: The code change proposal will decrease the cost of construction

There is a small likelihood that points potentially gained by this code change would result in a decrease in cost. This is dependent on the total building score on Table 1301.7 and other decisions made by the applicant.
EB128-19

2018 International Existing Building Code

Revise as follows:

1301.6.12 Dead ends. In spaces required to be served by more than one means of egress, evaluate the length of the exit access travel path in which the building occupants are confined to a single path of travel. Under the categories and occupancies in Table 1301.6.12, determine the appropriate value and enter that value into Table 1301.7 under Safety Parameter 1301.6.12, Dead Ends, for means of egress and general safety.

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-2, E</td>
<td>-2</td>
<td>0</td>
<td>2</td>
<td>-4</td>
<td></td>
</tr>
<tr>
<td>I-2</td>
<td>-2</td>
<td>-6</td>
<td>0</td>
<td>-2</td>
<td>2</td>
</tr>
</tbody>
</table>

a. For dead-end distances between categories, the dead-end value shall be obtained by linear interpolation based on the longest dead-end corridor.

1301.6.12.1 Categories. The categories for dead ends are:

1. Category a-Dead end of ends exceeding Category b.
2. Category b-Dead end not greater than 35 feet (10 670 mm) in nonsprinklered buildings or 70 feet (21 340 mm) in sprinklered buildings.
3. Category c-Dead end of not greater than 20 feet (6096 mm); or 50 feet (15 240 mm) in Group Groups B, E, F, M, R-1, R-2, R-4 and S in accordance with Section 1020.4, Exception 2, of the International Building Code.
4. Category d-No dead ends; or ratio of length to width (l/w) is less than 2.5:1. Category d-Dead ends exceeding Category a.

Reason: This code change accomplishes several things:

1. Table 1301.6.12 currently has failure modes at both ends of the table (Categories a and d). This is completely contrary to all of the other tables in Chapter 134. This revision places both failure modes as Categories a and b. This is consistent with the other tables in Chapter 13 and will reduce confusion in application of the table. As a result of revising the category order, Section 1301.6.12.1 is reorganized to match the table format.

2. The values for Group A-2 and E are identical to the scores for Groups A-1, A-3, A-4, B, F, M, R, and S. Therefore, the separate row for A-2 and E is deleted and these occupancies are moved into the row with the other occupancies.

3. Correlation of the new Category c with the current provisions in the IBC for new construction, otherwise the building will receive a deficit even though the building complies with the code. The current requirement states that only dead-end corridors in Group B occupancies can be up to 50 feet in length. However, the 2018 IBC allows dead-end corridors up to 50 feet in length in Group B, E, F, M, R-1, R-2, R-4, and S occupancies.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is editorial for clarity and correlation.
Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Existing Building Code

Revise as follows:

1301.6.16.1 Categories. The categories for mixed occupancies are:

1. Category a—Occupancies separated by minimum 1-hour fire barriers or minimum 1-hour horizontal assemblies, or both.
2. Category b—Separations between occupancies in accordance with Section 508.4 of the International Building Code.
3. Category c—Separations between occupancies having a fire-resistance rating of not less than twice the 1-hour, 2-hour, 3-hour or 4-hour fire-resistance ratings that are specified in Table 508.4 where that required by Section 508.4 of the International Building Code.

Reason: The original intent was to provide a benefit where a wall provided double the hourly rating required for some type of separation. The rewording is simply to not allow for a project to get points for a wall with a zero rating.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a rating system and design alternative, not a requirement.
2018 International Existing Building Code

Revise as follows:

1301.9.1 Mixed occupancies. For mixed occupancies, the following provisions shall apply:

1. Where the separation between mixed occupancies does not qualify for any category indicated in Section 1301.6.16, the mandatory safety scores for the occupancy with the lowest general safety score in Table 1301.8 shall be utilized (see Section 1301.6).

2. Where the separation between mixed occupancies qualifies for any category indicated in Section 1301.6.16, the mandatory safety scores for each occupancy shall be placed against the evaluation scores for the appropriate occupancy. An evaluation is not required for areas of the building with separated occupancies in accordance with Table 508.4 of the International Building Code in which there are no alterations or change of occupancy.

Reason: The code text is intended to address a condition with multiple occupancies that are being altered or changed in occupancy classification. It does not address the situation where only portions of the building within the building are being changed. This added text is make it clear that while the portions altered or changed can have multiple separated occupancies, this does not have any bearing for the separated areas outside the work areas being addressed by the performance method.

Cost Impact: The code change proposal will decrease the cost of construction

By clarifying what happens with partial change in occupancy and conditions of mixed occupancies within the separated areas that are proposed to change in occupancy, the cost to the remainder of the building is decreased.
EB131-19
IEBC®: TABLE 1301.6.20, 1301.6.20.1

Proponent: Jeffrey Harper, JENSEN HUGHES, representing JENSEN HUGHES (jharper@jensenhughes.com); Sean Donohue, representing JENSEN HUGHES (sdonohue@jensenhughes.com)

2018 International Existing Building Code

Revise as follows:

TABLE 1301.6.20

SMOKE COMPARTMENTATION VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES^a</th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>A, B, E, F, M, R and S</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>I-2</td>
<td>0</td>
<td>NP</td>
<td>-10</td>
<td>NP</td>
<td>-10</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.093 m².

NP = Not Permitted.

a. For areas between categories, the smoke compartmentation value shall be obtained by linear interpolation.

1301.6.20.1 Categories. Categories for smoke compartment size are:

1. Category a-Smoke compartment size is equal to or less than 22,500 square feet (2092 m²) - in a Group I-2, Condition 1 occupancy; or less that 40,000 square feet (3716 m²) in a Group I-2, Condition 2 occupancy as prescribed by IBC 407.5.1.
2. Category b-Smoke compartment size is greater than 22,500 square feet (2092 m²) - in a Group I-2, Condition 1 occupancy.
3. Category c-Smoke compartment size is greater than 40,000 square feet (3716 m²) in a Group I-2, Condition 2 occupancy.
4. Category d-Smoke compartments are not provided.

Reason: The effect of this table as currently written is to either allow or disallow the use of the performance compliance method for Group I-2 occupancies. There is no middle ground to account for a deficient smoke compartment. I-2 occupancies that fall under category 'b' should not create an automatic fail (NP), but rather should be assigned a certain negative value. Being over the maximum smoke compartment size does not cause the NFPA 101-A FSES to fail automatically; and if the intent is to echo the process, then it should cause a similar scoring condition. Currently, FSES allows smoke compartments that are greater than that required by the applicable governing section of NFPA 101. Having category 'b' as automatic fail contradicts this intent. A value of -10 has been chosen to show that the importance of smoke compartmentation is on par with the inclusion of sprinkler protection.

Lastly, the table has been adjusted to reflect the difference between I-2 conditions 1 and 2 having different allowable smoke compartment sizes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This code provision will not increase cost and has a high likelihood of reducing cost by providing flexibility that does not currently exist in the code.

Proposal # 5477
2018 International Existing Building Code
Revise as follows:

**TABLE 1301.6.21.1**
PATIENT ABILITY VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-2</td>
<td></td>
<td>3</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

**TABLE 1301.6.21.2**
PATIENT CONCENTRATION VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-2</td>
<td></td>
<td>3</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

**TABLE 1301.6.21.3**
ATTENDANT-TO-PATIENT RATIO VALUES

<table>
<thead>
<tr>
<th>OCCUPANCY</th>
<th>CATEGORIES</th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-2</td>
<td></td>
<td>3</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

**Reason:** The point values for categories ‘a’ and ‘c’ in these three tables were incorrectly arranged during the original code change process and are not providing the higher score for what is the better situation and should be reversed in each of the three tables. In Table 1301.6.21.1, Category ‘a’ states “patients are capable of self-preservation without assistance.” On the other hand, category ‘c’ states that “patients cannot be evacuated or relocated.” Regarding means of egress and general safety, patient’s ability to be mobile should be awarded more points. In Table 1301.6.21.2, Category ‘a’ states “smoke compartment has 1 to 10 patients.” Category ‘c’, on the other hand, states “smoke compartment has more than 40 patients.” The more patients there are in a single compartment, the worse it is in regard to means of egress and general safety. Thus, category ‘c’ should be awarded less points, having a higher concentration of patients. And finally in Table 1301.6.21.3, Category ‘a’ states “attendant-to-patient concentration is 1:5.” Category ‘c’ states “attendant-to-patient concentration is greater than 1:10 or no patients.” When it comes to means of egress and general safety, having a smaller attendant-to-patient ratio is more beneficial when compared to a larger ratio. Thus, category ‘a’ should be awarded more points as it has the smallest ratio.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code provision will not increase cost and has a high likelihood of reducing cost by providing flexibility that does not currently exist in the code.
EB133-19

IEBC®: (New), 1402.8 (New)

Proponent: Ali Fattah, City of San Diego, representing City of San Diego (afattah@sandiego.gov)

2018 International Existing Building Code

Add new definition as follows:

**WILDLAND-URBAN INTERFACE AREA.** That geographical area where structures and other human development meets or intermingles with wildland or vegetative fuels.

Add new text as follows:

1402.8 Wildland-Urban Interface Areas. If moved into a wildland-urban interface area, buildings shall comply with the International Wildland-Urban Interface Code as applicable.

   Exception: Buildings previously located in a wildland-urban interface area or moved within a wildland-urban interface area.

Reason: The wildland-urban interface code provides additional building standards for buildings subjected to fire hazards within a wildland-urban interface area and as a result are subject the increased fire risk when relocated into such an area. The Scope of Section 101.2 of the IWUIC includes moved buildings. This code change merely correlates the two codes. The alterations Sections are not proposed to be amended nor is an exception being added for historical buildings to allow local jurisdictions to determine whether to exempt their historical resources or exterior building alterations from from compliance. It makes no sense that if a building is moved to a vacant lot that a site built adjacent building is required to satisfy WUI regulations but not the relocated building.

Cost Impact: The code change proposal will increase the cost of construction

By moving a building into a WUI area the exterior roof, walls and openings may require upgrading. However the cost of the enhanced protection will provide a community benefit since in the WUI it is not unusual for conflagration hazards to occur when non compliant buildings burn and expose compliant buildings to hazards that they were not quite designed for since exterior fire fighting supression may not be available to control the non-compliant building.
2018 International Existing Building Code

Revise as follows:

[A] 101.4.2 Buildings previously occupied. The legal occupancy of any building existing on the date of adoption of this code shall be permitted to continue without change, except as is specifically covered in Chapter 16 of this code, the International Fire Code, or the International Property Maintenance Code, or as is deemed necessary by the code official for the general safety and welfare of the occupants and the public.

Add new text as follows:

**CHAPTER 16 CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS**

1601.1 Scope The provisions of this chapter shall apply to existing buildings constructed prior to the adoption of this code.

1601.2 Intent. The intent of this chapter is to provide a minimum degree of fire and life safety to persons occupying existing buildings by providing minimum construction requirements where such existing buildings do not comply with the minimum requirements of the International Building Code.

1601.3 Compliance. Existing buildings shall comply with not less than the minimum provisions specified in Chapter 11 of the International Fire Code and the International Property Maintenance Code prior to the application of the requirements in the International Existing Building Code.

1601.4 Owner notification. When a building is found to be in noncompliance with Section 1601.3, the code official shall duly notify the owner of the building or owner's authorized agent. Upon receipt of such notice, the owner or owner's authorized agent shall, subject to the following time limits, take necessary actions to comply with the provisions of this chapter.

1601.4.1 Construction documents. Construction documents necessary to comply with Section 1601.3 shall be completed and submitted within a time schedule approved by the code official.

1601.4.2 Completion of work. Work necessary to comply with this chapter shall be completed within a time schedule approved by the code official.

1601.4.3 Extension of time. The code official is authorized to grant necessary extensions of time where it can be shown that the specified time periods are not physically practical or pose an undue hardship. The granting of an extension of time for compliance shall be based on the showing of good cause and subject to the filing of an acceptable systematic plan of correction with the code official.

Reason: The IEBC, as expressly stated in the scope (Section 101.2) only applies when work is being done. It does not establish the minimum requirements for existing buildings. The International Fire Code, Chapter 11, establishes the minimum threshold of existing buildings.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal just clarifies the intent of how the code should be enforced. There is no impact to cost.
THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

301.1 General. The repair, alteration, change of occupancy, addition or relocation of all existing buildings shall comply with Section 301.2, 301.3, or 301.4. Structural work shall comply with Chapter 16.

301.3 Alteration, addition or change of occupancy. The alteration, addition or change of occupancy of all existing buildings shall comply with one of the methods listed in Section 301.3.1, 301.3.2 or 301.3.3 as selected by the applicant. Sections 301.3.1 through 301.3.3 shall not be applied in combination with each other.

Exception: Subject to the approval of the code official, alterations complying with the laws in existence at the time the building or the affected portion of the building was built shall be considered in compliance with the provisions of this code. New structural members added as part of the alteration shall comply with the International Building Code. This exception shall not apply to alterations that constitute substantial improvement in flood hazard areas, which shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable. This exception shall not apply to the structural provisions of Chapter 16, or to the structural provisions of Sections 706, 806 and 906.

Add new text as follows:

SECTION 1601
ADMINISTRATION

[BS] 1601.1 Scope The provisions of this chapter shall govern the structural design of repairs, alterations, changes of occupancy, additions or relocations of all existing buildings, structures and portions thereof regulated by this code

Revise as follows:

[BS] 507.3 1601.2 Flood hazard areas. Within flood hazard areas established in accordance with Section 1612.3 of the International Building Code, or Section R322 of the International Residential Code, as applicable, where the work proposed constitutes substantial improvement, the building shall be brought into compliance with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

Exception: Historic buildings meeting any of the following criteria need not be brought into compliance:

1. Listed or preliminarily determined to be eligible for listing in the National Register of Historic Places.
2. Determined by the Secretary of the U.S. Department of Interior as contributing to the historical significance of a registered historic district or a district preliminarily determined to qualify as an historic district.
3. Designated as historic under a state or local historic preservation program that is approved by the Department of Interior.

Add new text as follows:

SECTION 1602
GENERAL PROVISIONS

[BS] 1602.1 Existing Materials Use of existing materials shall comply with section 302.4.

[BS] 1602.2 New and replacement materials. New and replacement materials shall comply with section 302.5.
Revise as follows:

[BS] 303.3.1 **New structural members and connections.** New structural members and connections shall comply with the detailing provisions of the International Building Code for new buildings of similar structure, purpose and location.

**Exception:** Where alternative design criteria are specifically permitted.

## SECTION 303 1603

### STRUCTURAL DESIGN LOADS AND EVALUATION AND DESIGN PROCEDURES

**[BS] 1603.1 Live loads.** Where an addition or alteration does not result in increased design live load, existing gravity load-carrying structural elements shall be permitted to be evaluated and designed for live loads approved prior to the addition or alteration. If the approved live load is less than that required by Section 1607 of the International Building Code, the area designated for the nonconforming live load shall be posted with placards of approved design indicating the approved live load. Where the addition or alteration results in increased design live load, the live load required by Section 1607 of the International Building Code shall be used.

**[BS] 1603.2 Snow loads on adjacent buildings.** Where an alteration or addition changes the potential snow drift effects on an adjacent building, the code official is authorized to enforce Section 7.12 of ASCE 7.

**[BS] 1603.3 Seismic evaluation and design procedures.** Where required, seismic evaluation or design shall be based on the procedures and criteria in this section, regardless of which compliance method is used.

**[BS] 1603.3.1 Compliance with full seismic forces.** Where compliance requires the use of full seismic forces, the criteria shall be in accordance with one of the following:

1. One-hundred percent of the values in the International Building Code. Where the existing seismic force-resisting system is a type that can be designated as “Ordinary,” values of $R$, $A_{cd,0}$ and $C_{fr}$ used for analysis in accordance with Chapter 16 of the International Building Code shall be those specified for structural systems classified as “Ordinary” in accordance with Table 12.2-1 of ASCE 7, unless it can be demonstrated that the structural system will provide performance equivalent to that of a “Detailed,” “Intermediate” or “Special” system.

2. ASCE 41, using a Tier 3 procedure and the two-level performance objective in Table 303.3.1 for the applicable risk category.

**[BS] TABLE 303.3.1**

**[BS] 1603.3.2 Compliance with reduced seismic forces.** Where seismic evaluation and design is permitted to use reduced seismic forces, the criteria used shall be in accordance with one of the following:

1. The International Building Code using 75 percent of the prescribed forces. Values of $R$, $A_{cd,0}$ and $C_{fr}$ used for analysis shall be as specified in Section 303.3.1 of this code.

2. Structures or portions of structures that comply with the requirements of the applicable chapter in Appendix A as specified in Items 2.1 through 2.4 and subject to the limitations of the respective Appendix A chapters shall be deemed to comply with this section.

2.1. The seismic evaluation and design of unreinforced masonry bearing wall buildings in Risk Category I or II are permitted to be based on the procedures specified in Appendix Chapter A1.

2.2. Seismic evaluation and design of the wall anchorage system in reinforced concrete and reinforced masonry wall buildings with flexible diaphragms in Risk Category I or II are permitted to be based on the procedures specified in Chapter A2.

2.3. Seismic evaluation and design of cripple walls and sill plate anchorage in residential buildings of light-frame wood construction in Risk Category I or II are permitted to be based on the procedures specified in Chapter A3.

2.4. Seismic evaluation and design of soft, weak, or open-front wall conditions in multiple-unit residential buildings of wood construction in Risk Category I or II are permitted to be based on the procedures specified in Chapter A4.

3. ASCE 41, using the performance objective in Table 303.3.2 for the applicable risk category.

a. For Risk Categories I, II and III, the Tier 1 and Tier 2 procedures need not be considered for the BSE-1E earthquake hazard level.

b. For Risk Category III, the Tier 1 screening checklists shall be based on the Collapse Prevention, except that checklist statements using the Quick Check provisions shall be based on MS-factors that are the average of the values for Collapse Prevention and Life Safety.

c. For Risk Category IV, the Tier 1 screening checklists shall be based on Collapse Prevention, except that checklist statements using the Quick Check provisions shall be based on MS-factors for Life Safety.

**SECTION 304 1604**

**IN-SITU LOAD TESTS**

[BS] 304.1 1604.1 General. Where used, in-situ load tests shall be conducted in accordance with Section 1708 of the International Building Code.

**SECTION 405 1605**

**STRUCTURAL REPAIRS**

[BS] 405.1 1605.1 General. Structural repairs shall be in compliance with this section and Section 401.2.

[BS] 405.2 1605.2 Repairs to damaged buildings. Repairs to damaged buildings shall comply with this section.

[BS] 405.2.1 1605.2.1 Repairs for less than substantial structural damage. Unless otherwise required by this section, for damage less than substantial structural damage, the damaged elements shall be permitted to be restored to their predamage condition.

[BS] 405.2.1.1 1605.2.1.1 Snow damage. Structural components whose damage was caused by or related to snow load effects shall be repaired, replaced or altered to satisfy the requirements of Section 1608 of the International Building Code.

[BS] 405.2.2 1605.2.2 Disproportionate earthquake damage. A building assigned to Seismic Design Category D, E or F that has sustained disproportionate earthquake damage shall be subject to the requirements for buildings with substantial structural damage to vertical elements of the lateral force-resisting system.

[BS] 405.2.3 1605.2.3 Substantial structural damage to vertical elements of the lateral force-resisting system. A building that has sustained substantial structural damage to the vertical elements of its lateral force-resisting system shall be evaluated in accordance with Section 405.2.3.1 and either repaired in accordance with Section 405.2.3.2 or repaired and retrofitted in accordance with Section 405.2.3.3, depending on the results of the evaluation.

Exceptions:

1. Buildings assigned to Seismic Design Category A, B or C whose substantial structural damage was not caused by earthquake need not be evaluated or retrofitted for load combinations that include earthquake effects.

2. One- and two-family dwellings need not be evaluated or retrofitted for load combinations that include earthquake effects.

[BS] 405.2.3.1 Evaluation. The building shall be evaluated by a registered design professional, and the evaluation findings shall be submitted to the code official. The evaluation shall establish whether the damaged building, if repaired to its predamage state, would comply with the provisions of the International Building Code for load combinations that include wind or earthquake effects, except that the seismic forces shall be the reduced seismic forces.

[BS] 405.2.3.2 1605.2.3.2 Extent of repair for compliant buildings. If the evaluation establishes that the building in its predamage condition complies with the provisions of Section 405.2.3.1, then the damaged elements shall be permitted to be restored to their predamage condition.

[BS] 405.2.3.3 1605.2.3.3 Extent of repair for noncompliant buildings. If the evaluation does not establish that the building in its predamage condition complies with the provisions of Section 405.2.3.1, then the building shall be retrofitted to comply with the provisions of this section. The wind loads for the repair and retrofit shall be those required by the building code in effect at the time of original construction, unless the damage was caused by wind, in which case the wind loads shall be in accordance with the International Building Code. The seismic loads for this retrofit design shall be those required by the building code in effect at the time of original construction, but not less than the reduced seismic forces.
[BS] 405.2.4 | 1605.2.4 Substantial structural damage to gravity load-carrying components. Gravity load-carrying components that have sustained substantial structural damage shall be rehabilitated to comply with the applicable provisions for dead and live loads in the International Building Code. Snow loads shall be considered if the substantial structural damage was caused by or related to snow load effects. Undamaged gravity load-carrying components that receive dead, live or snow loads from rehabilitated components shall also be rehabilitated if required to comply with the design loads of the rehabilitation design.

[BS] 405.2.4.1 | 1605.2.4.1 Lateral force-resisting elements. Regardless of the level of damage to vertical elements of the lateral force-resisting system, if substantial structural damage to gravity load-carrying components was caused primarily by wind or seismic effects, then the building shall be evaluated in accordance with Section 405.2.4.1 and, if noncompliant, retrofitted in accordance with Section 405.2.3.3.

Exceptions:

1. Buildings assigned to Seismic Design Category A, B, or C whose substantial structural damage was not caused by earthquake need not be evaluated or retrofitted for load combinations that include earthquake effects.
2. One- and two-family dwellings need not be evaluated or retrofitted for load combinations that include earthquake effects.

[BS] 405.2.5 | 1605.2.5 Flood hazard areas. In flood hazard areas, buildings that have sustained substantial damage shall be brought into compliance with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

Add new text as follows:

**1606**

**ADDITIONS**

**1606.1 General** Additions shall comply with section 502.1 and this section.

Revise as follows:

[BS] 406.3.1 | 1606.2 Flood hazard areas. Additions and foundations in flood hazard areas shall comply with the following requirements:

1. For horizontal additions that are structurally interconnected to the existing building:
   1.1. If the addition and all other proposed work, when combined, constitute substantial improvement, the existing building and the addition shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
   1.2. If the addition constitutes substantial improvement, the existing building and the addition shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
2. For horizontal additions that are not structurally interconnected to the existing building:
   2.1. The addition shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
   2.2. If the addition and all other proposed work, when combined, constitute substantial improvement, the existing building and the addition shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
3. For vertical additions and all other proposed work that, when combined, constitute substantial improvement, the existing building shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
4. For a raised or extended foundation, if the foundation work and all other proposed work, when combined, constitute substantial improvement, the existing building shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.
5. For a new foundation or replacement foundation, the foundation shall comply with Section 1612 of the International Building Code or Section R322 of the International Residential Code, as applicable.

[BS] 502.2 | 1606.3 Disproportionate earthquake damage. A building assigned to Seismic Design Category D, E or F that has sustained disproportionate earthquake damage shall be subject to the requirements for buildings with substantial structural damage to vertical elements of the lateral force-resisting system.

[BS] 502.4 | 1606.4 Existing structural elements carrying gravity load. Any existing gravity load-carrying structural element for which an addition and its related alterations cause an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose vertical load-carrying capacity is decreased as part of the addition and its related alterations shall be considered to be an altered element subject to the requirements of Section 502.3.1. Any existing element that will form part of the lateral load path for any part of the addition shall be considered to be an existing lateral load-carrying structural element subject to the requirements of Section 502.5.

Exception: Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the existing building and the addition together comply with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.
[BS] 503.5 1606.5 Existing structural elements carrying lateral load. Where the addition is structurally independent of the existing structure, existing lateral load-carrying structural elements shall be permitted to remain unaltered. Where the addition is not structurally independent of the existing structure, the existing structure and its addition acting together as a single structure shall be shown to meet the requirements of Sections 1609 and 1613 of the International Building Code using full seismic forces.

Exceptions:

1. Any existing lateral load-carrying structural element whose demand-capacity ratio with the addition considered is not more than 10 percent greater than its demand-capacity ratio with the addition ignored shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1613 of the International Building Code. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities shall account for the cumulative effects of additions and alterations since original construction.

2. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the existing building and the addition together comply with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

Add new text as follows:

1606.6 Storm shelters. Storm shelters shall comply with section 1106.

1607 ALTERATIONS

1607.1 General Alterations shall comply with section 503.1 and this section.

Revise as follows:

[BS] 503.3 1607.2 Existing structural elements carrying gravity load. Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose gravity load-carrying capacity is decreased as part of the alteration shall be shown to have the capacity to resist the applicable design dead, live and snow loads including snow drift effects required by the International Building Code for new structures.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is due entirely to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering.

[BS] 706.2 1607.2.1 Structural and construction loads. Structural roof components shall be capable of supporting the roof-covering system and the material and equipment loads that will be encountered during installation of the system.

[BS] 503.4 1607.3 Existing structural elements carrying lateral load. Except as permitted by Section 503.4.1607.5, where the alteration increases design lateral loads, results in a prohibited structural irregularity as defined in ASCE 7, or decreases the capacity of any existing lateral load-carrying structural element, the structure of the altered building or structure shall meet the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exception: Any existing lateral load-carrying structural element whose demand-capacity ratio with the alteration considered is not more than 10 percent greater than its demand-capacity ratio with the alteration ignored shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities shall account for the cumulative effects of additions and alterations since original construction.

[BS] 503.4.1 1607.4 Substantial structural alteration. Where the work area exceeds 50 percent of the building area and where work involves a substantial structural alteration, the lateral load-resisting system of the altered building shall satisfy the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes that are
altered based on the conventional light-frame construction methods of the International Building Code or in compliance with the provisions of the International Residential Code.

2. Where the intended alteration involves only the lowest story of a building, only the lateral load-resisting components in and below that story need comply with this section.

[BS] 503.49 1607.5 Voluntary lateral force-resisting system alterations. Structural alterations that are intended exclusively to improve the lateral force-resisting system and are not required by other sections of this code shall not be required to meet the requirements of Section 1609 or Section 1613 of the International Building Code, provided that all of the following apply:

1. The capacity of existing structural systems to resist forces is not reduced.
2. New structural elements are detailed and connected to existing or new structural elements as required by the International Building Code for new construction.
3. New or relocated nonstructural elements are detailed and connected to existing or new structural elements as required by the International Building Code for new construction.
4. The alterations do not create a structural irregularity as defined in ASCE 7 or make an existing structural irregularity more severe.

[BS] 503.49 1607.6 Roof diaphragms resisting wind loads in high-wind regions. Where the intended alteration requires a permit for reroofing and involves removal of roofing materials from more than 50 percent of the roof diaphragm of a building or section of a building located where the ultimate design wind speed is greater than 115 mph (51 m/s) in accordance with Figure 1609.3(1) of the International Building Code or in a special wind region as defined in Section 1609 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof-to-wall connections shall be evaluated for the wind loads specified in Section 1609 of the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in Section 1609 of the International Building Code.

[BS] 503.5 1607.7 Seismic Design Category F. Where the work area exceeds 50 percent of the building area, and where the building is assigned to Seismic Design Category F, the structure of the altered building shall meet the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

[BS] 503.6 1607.8 Bracing for unreinforced masonry parapets on reroofing. Where the intended alteration requires a permit for reroofing and involves removal of roofing materials from more than 25 percent of the roof area of a building assigned to Seismic Design Category D, E or F that has parapets constructed of unreinforced masonry, the work shall include installation of parapet bracing to resist out-of-plane seismic forces, unless an evaluation demonstrates compliance of such items. Reduced seismic forces shall be permitted.

[BS] 503.7 1607.9 Anchorage for concrete and reinforced masonry walls. Where the work area exceeds 50 percent of the building area, the building is assigned to Seismic Design Category C, D, E or F and the building’s structural system includes concrete or reinforced masonry walls with a flexible roof diaphragm, the alteration work shall include installation of wall anchors at the roof line, unless an evaluation demonstrates compliance of existing wall anchorage. Use of reduced seismic forces shall be permitted.

[BS] 503.8 1607.10 Anchorage for unreinforced masonry walls in major alterations. Where the work area exceeds 50 percent of the building area, the building is assigned to Seismic Design Category C, D, E or F and the building’s structural system includes unreinforced masonry bearing walls, the alteration work shall include installation of wall anchors at the floor and roof lines, unless an evaluation demonstrates compliance of existing wall anchorage. Reduced seismic forces shall be permitted.

[BS] 503.9 1607.11 Bracing for unreinforced masonry parapets in major alterations. Where the work area exceeds 50 percent of the building area, and where the building is assigned to Seismic Design Category C, D, E or F, parapets constructed of unreinforced masonry shall have bracing installed as needed to resist out-of-plane seismic forces, unless an evaluation demonstrates compliance of such items. Reduced seismic forces shall be permitted.

[BS] 503.10 1607.12 Anchorage of unreinforced masonry partitions in major alterations. Where the work area exceeds 50 percent of the building area, and where the building is assigned to Seismic Design Category C, D, E or F, unreinforced masonry partitions and nonstructural walls within the work area and adjacent to egress paths from the work area shall be anchored, removed or altered to resist out-of-plane seismic forces, unless an evaluation demonstrates compliance of such items. Use of reduced seismic forces shall be permitted.

[BS] 503.11 1607.13 Substantial structural alteration. Where the work area exceeds 50 percent of the building area and where work involves a substantial structural alteration, the lateral load-resisting system of the altered building shall satisfy the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes that are altered based on the conventional light-frame construction methods of the International Building Code or in compliance with the provisions of the International Residential Code.

2. Where the intended alteration involves only the lowest story of a building, only the lateral load-resisting components in and below that story need comply with this section.
Add new text as follows:

1608
CHANGE OF OCCUPANCY

1608.1 General. Change of occupancy shall comply with section 506.1 and this section.

Revise as follows:

506.4.1 1608.2 Live loads. Structural elements carrying tributary live loads from an area with a change of occupancy shall satisfy the requirements of Section 1607 of the International Building Code. Design live loads for areas of new occupancy shall be based on Section 1607 of the International Building Code. Design live loads for other areas shall be permitted to use previously approved design live loads.

Exception: Structural elements whose demand-capacity ratio considering the change of occupancy is not more than 5 percent greater than the demand-capacity ratio based on previously approved live loads need not comply with this section.

506.4.2 1608.3 Snow and wind loads. When a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608 and 1609 of the International Building Code for the new risk category.

Exception: Where the area of the new occupancy is less than 10 percent of the building area, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.

506.4.3 1608.4 Seismic loads (seismic force-resisting system). Where a change of occupancy results in a building being assigned to a higher risk category, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where the area of the new occupancy is less than 10 percent of the building area and the new occupancy is not assigned to Risk Category IV, compliance with this section is not required. The cumulative effect of occupancy changes over time shall be considered.
2. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33, compliance with this section is not required.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B, shall be permitted to use Appendix Chapter A1 of this code.

506.4.4 1608.5 Access to Risk Category IV. Any structure that provides operational access to an adjacent structure assigned to Risk Category IV as the result of a change of occupancy shall itself satisfy the requirements of Sections 1608, 1609 and 1613 of the International Building Code. For compliance with Section 1613, International Building Code-level seismic forces shall be used. Where operational access to the Risk Category IV structure is less than 10 feet (3048 mm) from either an interior lot line or from another structure, access protection from potential falling debris shall be provided.

Add new text as follows:

1609
HISTORIC BUILDINGS

1609.1 Report A historic building undergoing alteration or change of occupancy shall be investigated and evaluated, and a report prepared and filed in accordance with section 1201.2.

Revise as follows:

[BS] 507.4 1609.2 Structural: General. Historic buildings shall comply with the applicable structural provisions in this chapter.

Exceptions:

1. The code official shall be authorized to accept existing floors and existing live loads and to approve operational controls that limit the live load on any floor.
2. Repair of substantial structural damage is not required to comply with Sections 405.2.3, 1605.2.3, and 405.2.4, 1605.2.4. Substantial structural damage shall be repaired in accordance with Section 405.2.4, 1605.2.1.

[BS] 4095.2 1609.3 Dangerous conditions. Conditions determined by the code official to be dangerous shall be remedied. Work shall not be required beyond what is required to remedy the dangerous condition.

Add new text as follows:
1609.4 Relocated historic buildings. Relocated historic buildings shall comply with section 1206 and this section.

1610
RELOCATED BUILDINGS

1610.1 General. Relocated buildings shall comply with section 1401.2 and this section.

Revise as follows:

[BS] 1610.2 Foundation. The foundation system of relocated buildings shall comply with the International Building Code or the International Residential Code as applicable.

[BS] 1610.2.1 Connection to the foundation. The connection of the relocated building to the foundation shall comply with the International Building Code or the International Residential Code as applicable.

Exceptions:

1. Detached one- and two-family dwellings and Group U occupancies where wind loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 10 percent.

[BS] 1610.4 Seismic loads. Buildings shall comply with International Building Code or International Residential Code seismic provisions at the new location as applicable.

Exceptions:

1. Structures in Seismic Design Categories A and B and detached one- and two-family dwellings in Seismic Design Categories A, B and C where the seismic loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 10 percent.

[BS] 1610.5 Snow loads. Structures shall comply with International Building Code or International Residential Code snow loads as applicable where snow loads at the new location are higher than those at the previous location.

Exception: Structural elements whose stress is not increased by more than 5 percent.

[BS] 1610.6 Flood hazard areas. If relocated or moved into a flood hazard area, structures shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

[BS] 1610.7 Required inspection and repairs. The code official shall be authorized to inspect, or to require approved professionals to inspect at the expense of the owner, the various structural parts of a relocated building to verify that structural components and connections have not sustained structural damage. Any repairs required by the code official as a result of such inspection shall be made prior to the final approval.

Delete without substitution:

[BS] 401.3 Flood hazard areas. In flood hazard areas, repairs that constitute substantial improvement shall require that the building comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

[BS] 502.3 Flood hazard areas. For buildings and structures in flood hazard areas established in Section 1612.3 of the International Building Code, or Section R322 of the International Residential Code, as applicable, any addition that constitutes substantial improvement of the existing structure shall comply with the flood design requirements for new construction, and all aspects of the existing structure shall be brought into compliance with the requirements for new construction for flood design.

For buildings and structures in flood hazard areas established in Section 1612.3 of the International Building Code, or Section R322 of the International Residential Code, as applicable, any additions that do not constitute substantial improvement of the existing structure are not required to comply with the flood design requirements for new construction.

[BS] 503.2 Flood hazard areas. For buildings and structures in flood hazard areas established in Section 1612.3 of the International Building Code, or Section R322 of the International Residential Code, as applicable, any alteration that constitutes substantial improvement of the existing structure shall comply with the flood design requirements for new construction, and all aspects of the existing structure shall be brought into compliance with the requirements for new construction for flood design.

For buildings and structures in flood hazard areas established in Section 1612.3 of the International Building Code, or Section R322 of the International Residential Code, as applicable, any alterations that do not constitute substantial improvement of the existing structure are not required to comply with the flood design requirements for new construction.
**SECTION-706-STRUCTURAL**

**[BS]-706.1 General:** Where alteration work includes replacement of equipment that is supported by the building or where a reroofing permit is required, the provisions of this section shall apply.

**[BS]-706.2 Addition or replacement of roofing or replacement of equipment:** Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures.

**Exceptions:**

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is due entirely to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering.

**[BS]-706.3 Additional requirements for reroof permits:** The requirements of this section shall apply to alteration work requiring reroof permits.

**[BS]-706.3.1 Bracing for unreinforced masonry bearing wall parapets:** Where a permit is issued for reroofing or more than 25 percent of the roof area of a building assigned to Seismic Design Category D, E or F that has parapets constructed of unreinforced masonry, the work shall include installation of parapet bracing unless an evaluation demonstrates compliance of such items:

- Reduced seismic forces shall be permitted.

**[BS]-706.3.2 Roof diaphragms resisting wind loads in high-wind regions:** Where roofing materials are removed from more than 50 percent of the roof diaphragm or section of a building located where the ultimate design wind speed, Vuf, determined in accordance with Figure 1609.3(1) of the International Building Code, is greater than 115 mph (51 m/s) or in a special wind region, as defined in Section 1609 of the International Building Code, roof diaphragms, connections of the roof diaphragm to roof framing members, and roof to wall connections shall be evaluated for the wind loads specified in the International Building Code, including wind uplift. If the diaphragms and connections in their current condition are not capable of resisting 75 percent of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in the International Building Code.

**SECTION-806-STRUCTURAL**

**[BS]-806.1 General:** Structural elements and systems within buildings undergoing Level 2 alterations shall comply with this section.

**[BS]-806.2 Existing structural elements carrying gravity loads:** Any existing gravity load-carrying structural element for which an alteration causes an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose gravity load-carrying capacity is decreased as part of the alteration shall be shown to have the capacity to resist the applicable design dead, live and snow loads, including snow drift effects, required by the International Building Code for new structures.

**Exceptions:**

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the altered building complies with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

2. Buildings in which the increased dead load is attributable to the addition of a second layer of roof covering weighing 3 pounds per square foot (0.1437 kN/m²) or less over an existing single layer of roof covering.

**[BS]-806.3 Existing structural elements resisting lateral loads:** Except as permitted by Section 806.4, where the alteration increases design lateral loads, or where the alteration results in prohibited structural irregularity as defined in ASCE 7, or where an alteration decreases the capacity of any existing lateral load-carrying structural element, the structure of the altered building or structure shall meet the requirements of Sections 1609 and 1612 of the International Building Code. Reduced seismic forces shall be permitted.

**Exception:** Any existing lateral load-carrying structural element whose demand-capacity ratio with the alteration considered is not more than 10 percent greater than its demand-capacity ratio without the alteration shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1612 of the International Building Code. Reduced seismic forces shall be permitted.
The capacity of existing structural systems to resist forces is not reduced.

New structural elements are detailed and connected to existing or new structural elements as required by the International Building Code for new construction.

New or relocated nonstructural elements are detailed and connected to existing or new structural elements as required by the International Building Code for new construction.

The alterations do not create a structural irregularity as defined in ASCE-7 or make an existing structural irregularity more severe.

SECTION 906

STRUCTURAL

[BS] 906.1 General. Where buildings are undergoing Level 3 alterations, the provisions of this section shall apply.

[BS] 906.2 Existing structural elements resisting lateral loads. Where work involves a substantial structural alteration, the lateral load-resisting system of the altered building shall be shown to satisfy the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes that are altered based on the conventional light-frame construction methods of the International Building Code or in compliance with the provisions of the International Residential Code.

2. Where the intended alteration involves only the lowest story of a building, only the lateral load-resisting components in and below that story need comply with this section.

[BS] 906.3 Seismic Design Category F. Where the building is assigned to Seismic Design Category F, the structure of the altered building shall meet the requirements of Sections 1609 and 1613 of the International Building Code. Reduced seismic forces shall be permitted.

[BS] 906.4 Anchorage for concrete and masonry buildings. For any building assigned to Seismic Design Category D, E or F with a structural system that includes concrete or reinforced masonry walls with a flexible roof diaphragm, the alteration work shall include installation of wall anchors at the roof line of all subject buildings and at the floor lines of unreinforced masonry buildings unless an evaluation demonstrates compliance of existing wall anchorage. Reduced seismic forces shall be permitted.

[BS] 906.5 Anchorage for unreinforced masonry walls. For any building assigned to Seismic Design Category C, D, E or F with a structural system that includes unreinforced masonry bearing walls, the alteration work shall include installation of wall anchors at the roof line, unless an evaluation demonstrates compliance of existing wall anchorage. Reduced seismic forces shall be permitted.

[BS] 906.6 Bracing for unreinforced masonry parapets. Parapets constructed of unreinforced masonry in buildings assigned to Seismic Design Category C, D, E or F shall have bracing installed as needed to resist the reduced international Building Code level seismic forces in accordance with Section 393.3, unless an evaluation demonstrates compliance of such items. Use of reduced seismic forces shall be permitted.

[BS] 906.7 Anchorage of unreinforced masonry partitions. Where the building is assigned to Seismic Design Category C, D, E or F, unreinforced masonry partitions and nonstructural walls within the work area and adjacent to egress paths from the work area shall be anchored, removed, or altered to resist out-of-plane seismic forces, unless an evaluation demonstrates compliance of such items. Use of reduced seismic forces shall be permitted.

SECTION 1006

STRUCTURAL

[BS] 1006.1 Live loads. Structural elements carrying tributary live loads from an area with a change of occupancy shall satisfy the requirements of Section 1607 of the International Building Code. Design live loads for areas of new occupancy shall be based on Section 1607 of the International Building Code. Design live loads for other areas shall be permitted to use previously approved design live loads.

Exception: Structural elements whose demand-capacity ratio considering the change of occupancy is not more than 5 percent greater than the demand-capacity ratio based on previously approved live loads.

[BS] 1006.2 Snow and wind loads. Where a change of occupancy results in a structure being assigned to a higher risk category, the structure shall satisfy the requirements of Sections 1608 and 1609 of the International Building Code for the new risk category.
Exception: Where the area of the new occupancy is less than 10 percent of the building area. The cumulative effect of occupancy changes over time shall be considered.

[BS]1006.3 Seismic loads. Where a change of occupancy results in a building being assigned to a higher risk category, the building shall satisfy the requirements of Section 1613 of the International Building Code for the new risk category using full seismic forces.

Exceptions:

1. Where a change of use results in a building being reclassified from Risk Category I or II to Risk Category III and the seismic coefficient, SDS, is less than 0.33.
2. Where the area of the new occupancy is less than 10 percent of the building area and the new occupancy is not assigned to Risk Category IV. The cumulative effect of occupancy changes over time shall be considered.
3. Unreinforced masonry bearing wall buildings assigned to Risk Category III and to Seismic Design Category A or B shall be permitted to use Appendix Chapter A1 of this code.

[BS]1006.4 Access to Risk Category IV. Any structure that provides operational access to an adjacent structure assigned to Risk Category IV as the result of a change of occupancy shall satisfy the requirements of Sections 1608, 1609 and 1613 of the International Building Code. For compliance with Section 1613, the full seismic forces shall be used. Where operational access to Risk Category IV is less than 10 feet (3048 mm) from either an interior lot line or from another structure, access protection from potential falling debris shall be provided.

SECTION 1103 STRUCTURAL:

[BS]1103.1 Additional gravity loads. Any existing gravity load-carrying structural element for which an addition and its related alterations cause an increase in design dead, live or snow load, including snow drift effects, of more than 5 percent shall be replaced or altered as needed to carry the gravity loads required by the International Building Code for new structures. Any existing gravity load-carrying structural element whose gravity load-carrying capacity is decreased as part of the addition and its related alterations shall be considered to be an altered element subject to the requirements of Section 806.2. Any existing element that will form part of the lateral load path for any part of the addition shall be considered to be an existing lateral load-carrying structural element subject to the requirements of Section 1103.3.

Exception: Buildings of Group R occupancy with not more than five dwelling units or sleeping units used solely for residential purposes where the existing building and the addition together comply with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.

[BS]1103.2 Lateral force-resisting system. Where the addition is structurally independent of the existing structure, existing lateral load-carrying structural elements shall be permitted to remain unaltered. Where the addition is not structurally independent of the existing structure, the existing structure and its addition acting together as a single structure shall meet the requirements of Sections 1609 and 1613 of the International Building Code using full seismic forces.

Exceptions:

1. Buildings of Group R occupancy with not more than five dwelling or sleeping units used solely for residential purposes where the existing building and the addition comply with the conventional light-frame construction methods of the International Building Code or the provisions of the International Residential Code.
2. Any existing lateral load-carrying structural element whose demand-capacity ratio with the addition considered is not more than 10 percent greater than its demand-capacity ratio with the addition ignored shall be permitted to remain unaltered. For purposes of calculating demand-capacity ratios, the demand shall consider applicable load combinations with design lateral loads or forces in accordance with Sections 1609 and 1613 of the International Building Code. For purposes of this exception, comparisons of demand capacity ratios and calculation of design lateral loads, forces and capacities shall account for the cumulative effects of additions and alterations since original construction.

[BS]1201.4 Flood hazard areas. In flood hazard areas, if all proposed work, including repairs, work required because of a change of occupancy, and alterations, constitutes substantial improvement, then the existing building shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable.

Exception: If a historic building will continue to be a historic building after the proposed work is completed, then the proposed work is not considered a substantial improvement. For the purposes of this exception, a historic building is any of the following:

1. Listed or preliminarily determined to be eligible for listing in the National Register of Historic Places.
2. Determined by the Secretary of the U.S. Department of Interior to contribute to the historical significance of a registered historic district or a district preliminarily determined to qualify as a historic district.
3. Designated as historic under a state or local historic preservation program that is approved by the Department of Interior.

SECTION 1205
STRUCTURAL

[BS]-1205.1 General. Historic buildings shall comply with the applicable structural provisions for the work as classified in Chapter 4 or 5.

Exceptions:

1. The code official shall be authorized to accept existing floors and existing live loads and to approve operational controls that limit the live load on any floor.
2. Repair of substantial structural damage is not required to comply with Sections 405.2.3 and 405.2.4. Substantial structural damage shall be repaired in accordance with Section 405.2.1.

[BS]-1301.3.3 Compliance with flood hazard provisions. In flood hazard areas, buildings that are evaluated in accordance with this section shall comply with Section 1612 of the International Building Code, or Section R322 of the International Residential Code, as applicable if the work covered by this section constitutes substantial improvement.

[BS]-1301.4.1 Structural analysis. The owner shall have a structural analysis of the existing building made to determine adequacy of structural systems for the proposed alteration, addition or change of occupancy. The analysis shall demonstrate that the building with the work completed is capable of resisting the loads specified in Chapter 16 of the International Building Code.

Reason: Proposal is to collect all of the structural provisions into one chapter, chapter 16. Reasons as follows:

1. Current IIBC has structural provisions in triplicate - once for prescriptive method, once for work area method, and once for performance method (albeit structural provisions for performance method are short, but have also been source of unnecessary confusion in the past). This represents unnecessary text, and for each code cycle, unnecessary work to maintain the same provisions across methods - structural work should be independent of the methodology used to determine architectural compliance.

2. Collection of structural provisions in one chapter will lead to better understanding of the code provisions by practicing engineers, and hence improved compliance with the intent of the code.

3. Trend towards differentiation by trade is already started in past code cycle - accessibility requirements have been consolidated in one location in chapter 3 applicable to all methods of compliance.

4. Disconnection of structural work from other trades in the code may release other trades to find the most beneficial compliance methodology, independent of structural constraints.

This proposal is almost entirely a re-numbering and relocation of existing provisions, only substantive change is that the the same structural provisions from the current prescriptive and work area methods will apply to the performance method.

Current Chapter 16 - Reference Standards - should be revised to Chapter 17.

Cost Impact: The code change proposal will decrease the cost of construction
Proposal will generally have no effect on hard construction costs. Should have some beneficial effect on soft costs due to collection of structural design information in one chapter. For performance based designs, may decrease cost of construction since full compliance with IBC structural provisions would no longer be required.
EB136-19

IEBC®: [BS] A106.2.2.2, ASTM Chapter A0 (New)

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A106.2.2.2 Concrete masonry units and structural clay load-bearing tile. Grouted or ungrouted hollow concrete masonry units shall be tested in accordance with ASTM C140. Grouted or ungrouted structural clay load-bearing tile shall be tested in accordance with ASTM C67.

Add new text as follows:

C67-14: Test Methods of Sampling and Testing Brick and Structural Clay Tile

Summary of the current problem and why it’s unacceptable: The current version of the Code (in Section A106.2.2.2) requires testing on clay tile to be conducted in accordance with ASTM C34, but this standard does not include any testing information.

How the proposal solves it, in concept: The proposed language removes an inappropriate reference to ASTM C34, and replaces it with ASTM C67.

Point by point explanation and rationale for each change: Section A106.2.2.2 currently states the following: “Grouted or ungrouted structural clay load-bearing tile shall be tested in accordance with ASTM C34.” However, ASTM C34 is a material specification (Standard Specification for Structural Clay Loadbearing Wall Tile), not a test specification.

C34 states that tests on hollow clay tile shall be in conformance with ASTM C67 Standard Test Methods for Sampling and Testing Brick and Structural Clay Tile, which is the same test standard for modern clay brick. The C34 material specification standard is intended for new units that are not already installed into an assembly.

However, a significant percentage of clay brick masonry and hollow clay tile masonry buildings are historic structures. Since the manufacturing processes and typical firing temperatures used in the production of clay masonry units has changed dramatically over the past 100 years, it is unlikely that historic clay masonry materials will meet modern material specifications. Therefore, mandating testing of historic units for comparison with modern standards such as ASTM C67 can be problematic in some circumstances.

Nonetheless, testing of clay tile masonry units installed in old/historic masonry structures in accordance with this standard may be the best approach available at this time.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Proposal provides corrected ASTM reference, no change to design or construction.

Staff Analysis: The referenced standard, ASTM C67, is currently referenced in other 2018 I-codes.
EB137-19

IEBC®: [BS] A106.2.2.2

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A106.2.2.2 A106.2.2.3.1 Concrete masonry units and structural clay load-bearing tile. Grouted or ungrouted hollow concrete masonry units shall be tested in accordance with ASTM C140. Grouted or ungrouted structural clay load-bearing tile shall be tested in accordance with ASTM C34.

Reason: Note that cdpAccess system did not let us modify existing section, so we have submitted under the "new section" section. Proposed modification is to relocate current section A106.2.2.2 to A106.2.3.

Proposes that Section A106.2.2.2 be incorporated into the portion of the Code that addresses masonry testing.

Section A106.2.2.2 deals with masonry testing, but it is located under Section A106.2.2, which is entitled “Lay-up of walls”. The testing is not related to the lay-up of masonry walls.

The proposed change moves masonry testing of concrete block and structural clay load-bearing tile into the “Testing of masonry” section.

Section A106.2.2.2 deals entirely with testing of masonry materials. However, it is located under Section A106.2.2 “Lay-up of walls”. The more appropriate location for these testing requirements would be under Section A106.2.3 “Testing of masonry.”

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Proposal does not change code requirement, simply relocates code subsection to a more appropriate section.

Proposal # 5565
EB138-19

IEBC®: [BS] A106.2.3.1, [BS] A106.2.3.2

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A106.2.3.1 In-place mortar joint shear tests. Mortar joint shear test values, \( v_{\text{sp}} \), shall be obtained by one of the following:

1. ASTM C1531.
2. For masonry walls that have high shear strength mortar, or where in-place testing is not practical because of crushing or other failure mode of the masonry, alternative procedures for testing shall be used in accordance with Section A106.2.3.2.

[BS] A106.2.3.2 Alternative test procedures for testing masonry. The tensile-splitting splitting tensile strength of existing masonry, \( f_{sp} \), or the prism strength of existing masonry, \( f_{pm} \), is permitted to be determined in accordance with ASTM C496 and calculated by the following equation:

\[
f_{sp} = \frac{0.493P}{a_{s}}
\]

(Equation A1-1)

Reason: Note that the cdpAccess system did not let us modify existing text, so it has been submitted under the "new text" section.

What the proposal does: Proposes that masonry tests be labeled so as to designate their intended purpose. Also, where necessary, the proposal changes the currently used test name so as to match the name in the referenced ASTM Standard.

Summary of the current problem and why it's unacceptable: The text of various sections (A106.2.3.1, A106.2.3.3, and A106.2.3.5) refer to shear test results. However, the current section heading language does not make it clear which tests are intended to provide information about shear capacity. The alternative procedure is described as splitting tensile test, but if the bed joints are oriented at 45 degrees from horizontal, this is actually a diagonal tension test, which is also effectively a measure of shear capacity.

How the proposal solves it, in concept: The proposed language provides more specific information to the user of the Code regarding the purpose of each type of masonry testing.

Point by point explanation and rationale for each change: While the purpose and function of ASTM C1531 testing is relatively clearly defined by the text as providing information related to masonry joint shear capacity, the purpose of the splitting tensile testing is not as clearly described. The later sections of the text reference masonry joint shear tests. The earlier sections describe "splitting tensile" behavior. Splitting tensile testing is generally associated with direct tensile capacity. However, if the test is conducted in the manner described in the 2015 IEBC (with bed joints oriented at a 45-degree angle), the failure will actually generally be a "diagonal tension" failure in the bed joint, which is more like a shear failure in a wall. There could be confusion by an engineer attempting to use this Code section regarding the purpose of the diagonal tension / splitting tensile testing as the section is currently written. Providing labels that describe the purpose of each type of test, and using test names that match those in the referenced ASTM Standards, would make the intent of each type of testing more clear.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Proposed modification clarifies the relevant masonry testing.
EB139-19

IEBC®: [BS] A106.2.3.6

Proponent: Michael Fillion, representing National Council of Structural Engineers Associations (mrf.structure@verizon.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A106.2.3.6 Minimum quality of masonry. Where the alternative procedures of Section A106.2.3.2 are used to determine masonry quality, the following minimums apply:

1. The minimum average value of tensile-splitting splitting tensile strength, \( f_{sp} \), as calculated by Equation A1-1 shall be 50 pounds per square inch (344.7 kPa).
2. Individual unreinforced masonry walls with average tensile-splitting splitting tensile strength of less than 50 pounds per square inch (344.7 kPa) shall be pointed and retested.
3. The lower-bound mortar strength \( f_{spk} \) is defined as the mean minus one standard deviation \( P_{D+L} \) of the tensile-splitting splitting tensile test values \( f_{sp} \).

Reason: What the proposal does: Clarifies the requirements for the alternative procedures for testing of existing masonry. It also corrects certain terminology used in the provision so that it correctly corresponds with the ASTM test method that the provision references.

Summary of the current problem and why it’s unacceptable: Section A106.2 of the IEBC includes what appear to be parallel sections regarding mortar testing and masonry testing. However, the labelling of these sections makes the intent of the code provisions unclear as to when and where the requirements of Section A106.2.3.6 are applicable.

Also, Section A106.2.3.2 references ASTM C496, which is titled Standard Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens. However, the terminology used throughout Section A106.2.3.6 incorrectly refers to tensile-splitting strength rather than to splitting tensile strength.

How the proposal solves it, in concept: The proposed language clarifies the relationship between Section A106.2.3.2 and Section A106.2.3.6. It also corrects terminology to correspond with the referenced ASTM standard.

Point by point explanation and rationale for each change: Section A106.2 of the IEBC includes what appear to be parallel sections regarding mortar testing and masonry testing. However, the labelling of these sections makes the intent of the code provisions unclear.

Section A106.2.3.1 is titled “In-place mortar tests.” The following section (A106.2.3.2) is titled “Alternative procedures for testing masonry” and describes splitting tensile strength testing. This labelling strongly suggests that the designer can choose either to test existing masonry mortar shear (using ASTM C1531), or the designer can elect to conduct splitting tensile testing. The language in Section A106.2.3.2 confirms that the splitting tensile test is an alternate approach.

However, later in the Section, there are two additional parallel paragraphs. The first is titled “A106.2.3.5 Minimum quality of mortar,” which appears to reference the mortar shear testing of A106.2.3.1. The following paragraph is labelled “A106.2.3.6 Minimum quality of masonry,” and it references minimum splitting tensile. However, the title and language of A106.2.3.6 do not indicate whether or not this is intended to be an alternate means of qualifying masonry or if, in fact, masonry must meet BOTH the minimum quality of mortar requirements of the previous section AND the minimum quality of masonry requirements of this section. If the intent is for this paragraph to provide an alternate approach to qualifying masonry, both the title and the introductory language should indicate that this paragraph is an alternate to the previous.

The reference to tensile-splitting strength is changed to splitting tensile strength to match ASTM C496 referenced in A106.2.3.2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Proposal clarifies that certain acceptance criteria is only relevant for the alternative procedures for masonry testing.
2018 International Existing Building Code

[BS] A202.1 Scope. The provisions of this chapter shall apply to wall anchorage systems that resist out-of-plane forces and to collectors in existing reinforced concrete or reinforced masonry buildings with flexible diaphragms. Wall anchorage systems that were designed and constructed in accordance with the 1997 Uniform Building Code, 1999 BOCA National Building Code, 1999 Standard Building Code or the 2000 and or subsequent editions of the International Building Code shall be deemed to comply with these provisions.

Reason: The proposal updates the benchmark codes to match ASCE 41-17. In ASCE 41-17, the latest edition of Seismic Evaluation and Retrofit of Existing Buildings, Table 3-2 gives benchmark codes deemed to comply with a safety-based retrofit such as that contemplated by Chapter A2. In Table 3-2, the only benchmarks given for tilt-up (PC1, PC1A) and reinforced masonry (RM1) structural systems are the 1997 UBC and 2000 IBC. Buildings designed with the NBC or SBC are not benchmarked.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Tilt-up or 1-story CMU buildings designed with the 1999 NBC or 1999 SBC that are not also in compliance with the 2000 IBC will no longer be benchmarked and therefore might be subject to retrofit costs, but these are expected to be exceptionally rare, and effectively non-existent in California and other high seismic areas that traditionally used the UBC.
EB141-19

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A203.1 Definitions. For the purpose of this chapter, the applicable definitions listed in Chapters 16, 19, 21, 22 and 23 of the International Building Code and the following shall apply:

Add new definition as follows:

CONTINUITY CONNECTOR A component, typically a plate, rod, strap, or hold-downs, that ensures load path continuity along the full length of a crosstie or strut.

CROSSTIE A member continuous across the main diaphragm that connects opposite wall lines and transfers out-of-plane wall anchorage forces into the diaphragm.

Revise as follows:

[BS] FLEXIBLE DIAPHRAGMS. DIAPHRAGM. Roofs and floors including, but not limited to, those A roof or floor sheathed with plywood, wood decking (1-by or 2-by) or metal decks without a concrete topping slabs.

Add new definition as follows:

STRUT A member continuous across a subdiaphragm that transfers out-of-plane wall anchorage forces into the subdiaphragm.

WALL ANCHORAGE SYSTEM The components comprising a complete load path for out-of-plane wall forces from the wall to the main diaphragm, typically including anchors embedded in or fastened to the wall; rods, straps, plates, hold-downs or other hardware; subdiaphragms and their chords; crossties; struts; and continuity connectors.

[BS] A205.3 Requirements for plans. The plans shall accurately reflect the results of the engineering investigation and design and shall show all pertinent dimensions and sizes for plan review and construction. The following shall be provided:

1. Floor plans and roof plans shall show existing framing construction, diaphragm construction, proposed wall anchors, crossties, and collectors. Existing nailing, anchors, crossties, and collectors shall be shown on the plans if they are considered part of the lateral force-resisting systems.
2. At elevations where there are alterations or damage, details shall show roof and floor heights, dimensions of openings, location and extent of existing damage and proposed repair.
3. Typical wall panel details and sections with panel thickness, height, pilasters and location of anchors shall be provided.
4. Details shall include existing and new anchors and the method of developing anchor forces into the diaphragm framing, existing and new crossties, and existing and new or improved support of roof and floor girders at pilasters or walls.
5. The basis for design and the building code used for the design shall be stated on the plans.

[BS] A206.3 Development of anchor loads into the diaphragm. Development of anchor loads into roof and floor diaphragms shall comply with Section 1613 of the International Building Code using horizontal forces that are 75 percent of those used for new construction.

In wood diaphragms, anchorage shall not be accomplished by use of toenails or nails subject to withdrawal. Wood ledgers, top plates or framing shall not be used in cross-grain bending or cross-grain tension. The continuous ties required in Section 1613 of the International Building Code shall be in addition to the diaphragm sheathing.

Lengths of development of anchor loads in wood diaphragms shall be based on existing field nailing of the sheathing unless existing edge nailing is positively identified on the original construction plans or at the site.

Exception: If continuously tied girders are present, the maximum spacing of the continuity ties is the greater of the girder spacing or 24 feet (7315 mm).

Reason: This proposal supplements the Chapter A2 definitions and corrects references to defined terms.

A203.1: The IBC now has all of its definitions in Chapter 2. There is no need to cite specific chapters or sections.
In addition to the added definitions, ASCE 7 already provides adequate definitions for two other terms used in the chapter: subdiaphragm and collector.

CONTINUITY CONNECTOR, CROSSTIE, STRUT: Definitions added to clarify the provisions and ensure consistency. The term “crosstie,” a single word with no hyphen, is consistent with the terminology used in ASCE 7 Section 12.11.2.2.1. (Some RWFD retrofit references, including the Los Angeles Building Code and the SEAOC commentary, refer to continuity connectors as “continuity ties.” However, continuity connectors is the more traditional term and is preferred in part because “continuity ties” is easily confused with the phrase “continuous crossties.”)

FLEXIBLE DIAPHRAGM(S): Make the defined term singular. Simplify the definition to match ASCE 7 Section 12.3.1.1, which refers only to “diaphragms constructed of untopped steel decking or wood structural panels.”

WALL ANCHORAGE SYSTEM: The proposed definition is based on ASCE 7 Section 12.11.2.2.1, which lists the components that need to be provided to carry the prescribed forces.

A205.3: Replace “cross-ties” with “crossties” in three places.

A206.3: In two places, the correct term “crossties” replaces similar but confusing wording. The crossties must be continuous, but ‘continuous ties’ or ‘continuity ties’ is confusingly close to ‘continuity connectors’.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal is editorial and therefore will have no effect on cost.
EB142-19
IEBC®: [BS] A203.1, [BS], (New), [BS] A206.2

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A203.1 Definitions. For the purpose of this chapter, the applicable definitions listed in Chapters 16, 19, 21, 22 and 23 of the International Building Code and the following shall apply:

[BS] FLEXIBLE DIAPHRAGMS. Roofs and floors including, but not limited to, those sheathed with plywood, wood decking (1-by or 2-by) or metal decks without concrete topping slabs.

Add new definition as follows:

WALL SEGMENT Any length of concrete or reinforced masonry wall not interrupted or intersected by a pilaster or vertical construction joint.

Revise as follows:

[BS] A206.2 Special requirements for wall anchorage systems. The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

The maximum spacing between wall anchors shall be 8 feet, and each wall segment shall have at least two wall anchors.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching the edge of plywood sheathing to steel ledgers is not considered compliant with the positive anchoring requirements of this chapter. Attaching the edge of steel decks to steel ledgers is not considered as providing the positive anchorage of this chapter unless testing or analysis is performed to establish shear values for the attachment perpendicular to the edge of the deck. Where steel decking is used as a wall anchor system, the existing connections shall be subject to field verification and the new connections shall be subject to special inspection.

Exception: Existing cast-in-place shear anchors are allowed to be used as wall anchors if the tie element can be readily attached to the anchors, and if the engineer or architect can establish tension values for the existing anchors through the use of approved as-built plans or testing and through analysis showing that the bolts are capable of resisting the total shear load (including dead load) while being acted on by the maximum tension force caused by an earthquake. Criteria for analysis and testing shall be determined by the building official.

Reason: This proposal adds a prescriptive requirement based on ASCE 41 Table 17-28, which considers the lack of two anchors per precast wall panel to be a potential deficiency. The 8-ft maximum spacing proposed is larger than the spacing that would be expected for a typical Chapter A2 retrofit and thus represents a limit to guard against unusual or extreme cases.

A definition of wall segment is provided to facilitate the new requirement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposal guards against extreme cases and will not apply frequently thus generally not affecting the cost of construction.

Proposal # 5708
2018 International Existing Building Code

Revise as follows:

[BS] A205.1 General. The seismic-resisting elements specified in this chapter shall comply with applicable provisions of Section 1613 of the International Building Code and Chapter 12 of ASCE 7, except as modified herein.

[BS] A206.1 Reinforced concrete and reinforced masonry wall anchorage. Concrete and masonry walls shall be anchored to all floors and roofs that provide lateral support for the wall in accordance with ASCE 7 Section 12.11.2. The anchorage shall provide a positive direct connection between the wall and floor or roof construction capable of resisting 75 percent of the horizontal forces specified in Section 1613 of the International Building Code, ASCE 7 Section 12.11.2.1.

Exceptions:

1. Existing walls need not be evaluated or retrofitted for bending between anchors.
2. Work required by this chapter need not consider shrinkage, thermal changes, or differential settlement.

[BS] A206.2 Special Additional requirements for wall anchorage systems. The wall anchorage system shall comply with the requirements of this section and of ASCE 7 Section 12.11.2.2.

The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching the edge of plywood sheathing to steel ledgers is not considered compliant with the positive anchoring requirements of this chapter. Attaching the edge of steel decks to steel ledgers is not considered as providing the positive anchorage of this chapter unless testing or analysis is performed to establish shear values for the attachment perpendicular to the edge of the deck. Where steel decking is used as a wall anchor system, the existing connections shall be subject to field verification and the new connections shall be subject to special inspection.

Exception: Existing cast-in-place shear anchors are allowed to be used as wall anchors if the tie element can be readily attached to the anchors, and if the engineer or architect can establish tension values for the existing anchors through the use of approved as-built plans or testing and through analysis showing that the bolts are capable of resisting the total shear load (including dead load) while being acted on by the maximum tension force caused by an earthquake. Criteria for analysis and testing shall be determined by the building official.

[BS] A206.3 Development of anchor loads--anchorage forces into the diaphragm. Development of anchor loads--the required anchorage forces into roof and floor diaphragms shall comply with the requirements of this section and of ASCE 7 Section 12.11.2.2. Section 1613 of the International Building Code using horizontal forces that are 75 percent of those used for new construction.

In wood diaphragms, anchorage shall not be accomplished by use of toenails or nails subject to withdrawal. Wood ledgers, top plates or framing shall not be used in cross-grain bending or cross-grain tension. The continuous ties required in Section 1613 of the International Building Code shall be in addition to the diaphragm sheathing. Lengths of development of anchor loads in wood diaphragms shall be based on existing field nailing of the sheathing unless existing edge nailing is positively identified on the original construction plans or at the site.

Exception: If continuously tied girders are present, the maximum spacing of the continuity ties is the greater of the girder spacing or 24 feet (7315 mm).

[BS] A206.4 Anchorage at pilasters. Anchorage at pilasters shall be designed for the tributary wall anchoring load per Section A206.1, considering the wall as a two-way slab. The edges of the two-way slab shall be considered to be fixed where there is continuity at pilasters and shall be considered to be pinned at roof and floor. Where pilasters are present, the wall anchorage system shall comply with the requirements of this section and of ASCE 7 Section 12.11.2.2.7. The pilasters or the walls immediately adjacent to the pilasters shall be anchored directly to the roof framing such that the existing vertical anchor bolts at the top of the pilasters are bypassed without permitting tension or shear failure at the top of the pilasters. The minimum anchorage force at a floor or roof between the pilasters shall be that specified in Section A206.1.

Exception: If existing vertical anchor bolts at the top of the pilasters are used for the anchorage, additional exterior confinement shall be provided.
as required to resist the total anchorage force.

Delete without substitution:

[BS] A206.5 Symmetry. Symmetry of wall anchorage and continuity connectors about the minor axis of the framing member is required.

Exception: Eccentricity shall be allowed where it can be shown that all components of forces are positively resisted. The resistance must be supported by calculations or tests.

[BS] A206.8 Collectors. If collectors are not present—Collectors designed in accordance with this section shall be provided at reentrant corners or and at interior shear walls, they shall be provided. Walls, existing or new collectors shall be designed to have the capacity required to develop into the diaphragm a force equal to the lesser of the rocking or shear capacity of the reentrant wall or the tributary shear based on 75 percent of the horizontal dia...
EB144-19

IEBC®: [BS] A205.2, [BS] A205.3

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Delete without substitution:

[BS] A205.2 Alterations and repairs. Alterations and repairs required to meet the provisions of this chapter shall comply with applicable structural requirements of the building code unless specifically modified in this chapter.

Revise as follows:

[BS] A205.3 Requirements for plans. The plans shall accurately reflect the results of the engineering investigation and design and shall show all pertinent dimensions and sizes for plan review and construction. The following shall be provided:

1. Floor plans and roof plans shall show existing framing construction, diaphragm construction, proposed wall anchors, cross-ties and collectors. Existing nailing, anchors, cross-ties and collectors shall be shown on the plans if they are considered part of the lateral force-resisting systems.
2. At elevations where there are alterations or damage, details shall show roof and floor heights, dimensions of openings, location and extent of existing damage and proposed repair.
3. Typical wall panel details and sections with panel thickness, height, pilasters and location of anchors shall be provided.
4. Details shall include existing and new anchors and the method of developing anchor forces into the diaphragm framing, existing and new cross-ties, and existing and new or improved support of roof and floor girders at pilasters or walls.
5. The basis for design and the building code used for the design shall be stated on the plans.

Reason: This proposal removes provisions that are unnecessary and outside the scope of Chapter A2. There is no need for Section A205.2, as the applicable codes already cover these same generic circumstances. Neither IEBC Chapter A3 nor IEBC Chapter A4 has a similar provision, demonstrating that it is unnecessary in Chapter A2. (IEBC Chapter A1 does have a similar provision, but it’s unnecessary and obsolete there, too.) Similarly, since alteration and repair (other than the contemplated retrofit) is outside the scope of Chapter A2, Section A205.3 item 2 is not needed and potentially misleading. Where other alterations or repairs are being made, the IEBC or governing code will already have provisions for proper documentation.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposal has no substantive impact as these provisions are addressed elsewhere.
EB145-19

IEBC®: [BS] A205.4, 205.5 (New), A205.6 (New)

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

[BS] A205.4 Structural observation, testing and inspection. Structural observation, in accordance with Section 1704.6 of the International Building Code, shall be required for all structures in which seismic retrofit is being performed in accordance with this chapter, is required, regardless of seismic design category, height, or other conditions. Structural observation shall include visual observation of work for conformance to the approved construction documents and confirmation of existing conditions assumed during design. Structural testing and inspection for new construction materials shall be in accordance with the building code, except as modified by this chapter.

Add new text as follows:

205.5 Contractor responsibility. Contractor responsibility shall be in accordance with Section 1704.4 of the International Building Code.

A205.6 Testing and Inspection Structural testing and inspection for new construction materials, submittals, reports, and certificates of compliance, shall be in accordance with Sections 1704 and 1705 of the International Building Code. Work done to comply with this chapter shall not be eligible for Exception 1 to International Building Code Section 1704.2, Exception 2 to International Building Code Section 1705.12, or the Exception to International Building Code Section 1705.12.2.

Reason: This proposal corrects a code reference and clarifies that typical quality assurance provisions from IBC Chapter 17 apply to Chapter A2 projects.

A205.4: For clarity, the current provision is broken into three subsections. Regarding structural observation, the proposal corrects a mistaken IBC section number and clarifies that the requirement applies despite IBC waivers for buildings of certain heights or assigned to certain seismic design categories.

A205.5: Regarding the contractor statement of responsibility, the proposed new section confirms that IBC section 1704.4 applies.

A205.6: Regarding testing and inspection, proposed Section A205.6 clarifies the existing reference to “the building code” and disallows certain exemptions in IBC Chapter 17 that apply to new construction of a minor nature but should not apply to Chapter A2 retrofits.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposal merely clarifies existing requirements. In rare cases, the cost of testing and inspection might increase slightly.

Proposal # 5704
AB146-19

IEBC®: A205.4.1 (New), A205.4.2 (New), A205.4.3 (New), [BS] A206.2

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new text as follows:

A205.4.1 Additional special inspection. In addition to the requirements of International Building Code Section 1705.12, special inspection shall be required for:

1. Installation of anchors into existing concrete or masonry walls to form part of a wall anchorage system.
2. Fastening of new or existing steel deck forming part of a wall anchorage system.

A205.4.2 Testing to establish adequacy of existing wall anchors. Testing shall show that the existing anchors can sustain a test load of 1.5 times the design tension load without noticeable deformation or damage to the anchor, to the masonry or concrete element, or to any part of the existing load path between the anchor and new retrofit components. Three anchors of each existing detail type shall be tested, and all three shall satisfy the requirement. Prior to testing, the design professional shall submit a test plan for code official approval identifying the expected locations of the existing anchors in question, the locations of the proposed tests, and the test procedure and criteria. After testing, the design professional shall submit a report of the satisfactory testing showing the test results, the design strengths derived from them, and the size and spacing as confirmed by investigation.

A205.4.3 Testing to establish adequacy of existing steel deck connections. Testing shall show that the existing construction can sustain a test load of 1.5 times the design load without noticeable deformation or damage to the deck, to the fasteners, or to any part of the existing load path. Three tests of each existing detail type shall be tested, and all three shall satisfy the requirement. Prior to testing, the design professional shall submit a test plan for code official approval including the findings of condition assessment, the expected locations of each detail type in question, the locations of the proposed tests, and the test procedure and criteria. After testing, the design professional shall submit a report of the satisfactory testing showing the test results and the design strengths derived from them.

[BS] A206.2 Special requirements for wall anchorage systems. The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching Wall anchorage shall not be provided solely by fastening the edge of plywood sheathing to steel ledgers. Wall anchorage shall not be provided solely by fastening the edge of steel decks to steel ledgers. Wall anchorage shall not be provided as part of the wall anchorage system unless testing or analysis is performed to establish shear values for the attachment perpendicular to the edge of the deck. Where steel decking is used as a wall anchor system, the unless testing in accordance with Section A205.4.3 establishes acceptable capacity. The existing connections shall be subject to field verification and the new connections shall be subject to special inspection.

New wall anchors shall be provided to resist the full wall anchorage design force independent of existing shear or tension anchors.

Exception: Existing cast-in-place shear anchors are allowed to be used as part of the wall anchorage system if the combination of anchors and bolts are capable of resisting the total vertical and lateral shear load (including dead load) while being acted on by the maximum wall anchorage tension force caused by an earthquake. Criteria for analysis and testing. Acceptable tension values for the existing anchors shall be determined by the building official, established by testing in accordance with Section A205.4.2.

Reason: This proposal coordinates the testing and inspection requirements given in Section A206.2 with Section A205.4, which is already meant to cover testing and inspection. It adds several new subsections to A205.4 to clarify the intent of the testing and inspection in Section A206.2. A205.4.1: The two listed conditions already require special inspection per Section A206.2.

A205.4.2: These test requirements are consistent with ASCE 41-17 Section 10.2.2.4.1, which addresses testing of cast-in-place and post-installed anchors in concrete, and which reads, in part, “If the test load is used as the basis for anchor strength calculation, the available anchor strength shall not be taken as greater than 2/3 of the test load.” Thus, successful tests to 1.5 times the design strength will justify use of the existing anchors. The requirement to test three existing anchors is also consistent with ASCE 41, though ASCE 41 requires testing 5 percent of the existing anchors.
as well, so in large buildings, the ASCE 41 requirement can be more conservative.

A205.4.3: These test requirements parallel those proposed in Section A205.4.2.

A206.2: This section is edited to coordinate with the new section on special inspection, as follows:

- The provision regarding expansion anchors is replaced by the special inspection requirement in A205.4.1 and the testing requirement in A205.4.2.
- The sentence regarding independent wall anchors is moved to the end of the section to be adjacent to the Exception; it is also edited for clarity. The Exception applies only to this part of Section A206.2. The Exception is edited for clarity and to refer to the new testing requirement in Section A205.4.2.
- The plywood provision is edited for clarity.
- The steel deck provision is edited for clarity, with a reference to the related inspection and testing requirements in A205.4.1 and A205.4.3.

Note that compliance of existing attachments by analysis is no longer considered reliable, so the provision has been modified to rely on testing alone.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposal merely clarifies existing requirements. In rare cases, the cost of testing and inspection might increase slightly.
EB147-19

IEBC®: A205.4.1 (New), [BS] A206.2

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new text as follows:

A205.4.1 Additional special inspection. In addition to the requirements of International Building Code Section 1705.12, special inspection shall be required for:

1. Installation of continuity connectors along the length of crossties, to ensure properly sized fastener holes and adequate crosstie stiffness.

[BS] A206.2 Special requirements for wall anchorage systems. The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

The wall anchorage system, excluding subdiaphragms and existing roof or floor framing members, shall be stiff enough to limit the relative movement between the wall and the diaphragm to no more than 1/8" before engagement of the anchors, when subject to the wall anchorage design forces.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching the edge of plywood sheathing to steel ledgers is not considered compliant with the positive anchoring requirements of this chapter. Attaching the edge of steel decks to steel ledgers is not considered as providing the positive anchorage of this chapter unless testing or analysis is performed to establish shear values for the attachment perpendicular to the edge of the deck. Where steel decking is used as a wall anchor system, the existing connections shall be subject to field verification and the new connections shall be subject to special inspection.

Exception: Existing cast-in-place shear anchors are allowed to be used as wall anchors if the tie element can be readily attached to the anchors, and if the engineer or architect can establish tension values for the existing anchors through the use of approved as-built plans or testing and through analysis showing that the bolts are capable of resisting the total shear load (including dead load) while being acted on by the maximum tension force caused by an earthquake. Criteria for analysis and testing shall be determined by the building official.

Reason: This proposal adds a stiffness requirement for the wall anchorage system. The proposed requirement is consistent with ASCE 41-17 Table 17-34. It has the same intent as a stiffness requirement discussed in the SEAOC commentary to IEBC Chapter A2 and implemented by the City of Los Angeles Department of Building and Safety. The SEAOC and Los Angeles approach limits the elongation under load. The ASCE 41 approach, which is the approach adopted here, limits the slack in the system (including continuity connectors along the length of the cross-ties) provided by the detailing and construction.

In addition to the proposed design criteria in Section A206.2, the proposal adds a special inspection requirement to Section A205.4 to ensure that additional slack is not introduced as continuity connectors are added to crossties.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Typical applications are expected to already satisfy the new stiffness requirement.
Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new text as follows:

A206.1.1 Seismicity parameters, Site Class, and geologic hazards. For any site designated as Site Class E, the value of $F_s$ shall be taken as 1.3. Site-specific procedures are not required for compliance with this chapter. Mitigation of existing geologic site hazards such as liquefiable soil, fault rupture, or landslide is not required for compliance with this chapter.

Reason: This proposal clarifies the intended scope of Chapter A2. The proposed clarifications have been vetted by the Structural Engineers Association of Northern California Existing Buildings Committee (SEAONC EBC) with respect to “soft story” retrofits and have been implemented as proposed here by an RWFD retrofit program in Berkeley, California.

The first two sentences simplify the application of IBC Section 1613 and ASCE 7 Section 12.11 to these retrofit projects, helping to keep them economically feasible. The value of $F_s = 1.3$, which is the default value for Site Class E in areas of high (but not highest or near-fault) seismicity, comes from a SEAONC EBC recommendation related to observed performance and recorded ground motions in the Loma Prieta earthquake. This value is allowed as a possibly conservative convenience, avoiding the need for expensive site-specific investigation (per ASCE 7 Table 11.4-1 and Section 11.4.8). Site-specific investigation remains an option, but is not required. This simplification is consistent in principle with the exceptions and waivers already provided in ASCE 7 Sections 11.4.8 and 20.3.1.

The site-specific ground motion procedures normally required by ASCE 7 Section 11.4.8 are waived for these retrofit projects. Many buildings eligible for Chapter A2 would be exempt from site response analysis by the exception to ASCE 7 Section 20.3.1.

The final proposed sentence clarifies that mitigation beyond the critical wall anchorage system is not intended by Chapter A2. Just as the chapter requires no retrofit of walls and no mitigation of nonstructural hazards, the proposal would waive geologic hazard mitigation that might be required for new construction or for more comprehensive triggered retrofits. Consistent with the limited scope of Chapter A2, these clarifications regarding geologic hazards are intended to keep Chapter A2 retrofits cost-effective.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

In some cases, it will decrease the cost of construction by avoiding the cost of investigation and mitigation. In some cases it will increase the cost of construction by defaulting to a possibly conservative value.
2018 International Existing Building Code

Revise as follows:

[BS] A206.2 Special requirements for wall anchorage systems. The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

Where new members are added as crossties, they shall be spaced no more than 24 feet (7315 mm) apart. Where existing girders are used as crossties, their actual spacing shall be deemed adequate even where the spacing exceeds 24 feet (7315 mm), as long as the girders are provided with adequate continuity connectors.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching the edge of plywood sheathing to steel ledgers is not considered compliant with the positive anchoring requirements of this chapter.

Exception: Existing cast-in-place shear anchors are allowed to be used as wall anchors if the tie element can be readily attached to the anchors, and if the engineer or architect can establish tension values for the existing anchors through the use of approved as-built plans or testing and through analysis showing that the bolts are capable of resisting the total shear load (including dead load) while being acted on by the maximum tension force caused by an earthquake. Criteria for analysis and testing shall be determined by the building official.

[BS] A206.3 Development of anchor loads into the diaphragm. Development of anchor loads into roof and floor diaphragms shall comply with Section 1613 of the International Building Code using horizontal forces that are 75 percent of those used for new construction.

In wood diaphragms, anchorage shall not be accomplished by use of toenails or nails subject to withdrawal. Wood ledgers, top plates or framing shall not be used in cross-grain bending or cross-grain tension. The continuous ties required in Section 1613 of the International Building Code shall be in addition to the diaphragm sheathing.

Lengths of development of anchor loads in wood diaphragms shall be based on existing field nailing of the sheathing unless existing edge nailing is positively identified on the original construction plans or at the site.

Exception: If continuously tied girders are present, the maximum spacing of the continuity ties is the greater of the girder spacing or 24 feet (7315 mm).

Reason: This editorial proposal corrects a misplaced provision and clarifies its intent. The current exception to Section A206.3 is out of place for two reasons. First, it is unrelated to the issue of load development into the diaphragm (crossties must be continuous across the full diaphragm width), so it really belongs in Section A206.2. Second, since ASCE 7 sets no limit on the maximum spacing of crossties, the provision is not really an exception at all. Therefore, as the existing text is relocated to Section A206.2, it has been edited to clarify the intended spacing limit and the allowance where existing members act as adequate crossties.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Editorial therefore will have no impact on cost.
EB150-19

IEBC®: [BS] A206.2

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A206.2 Special requirements for wall anchorage systems. The steel elements of the wall anchorage system shall be designed in accordance with the International Building Code without the use of the 1.33 short duration allowable stress increase where using allowable stress design.

Wall anchors shall be provided to resist out-of-plane forces, independent of existing shear anchors.

Expansion anchors are only allowed with special inspection and approved testing for seismic loading.

Attaching the edge of plywood sheathing to steel ledgers is not considered compliant with the positive anchoring requirements of this chapter. Attaching the edge of steel decks to steel ledgers is not considered as providing the positive anchorage of this chapter unless testing or analysis is performed to establish shear values for the attachment perpendicular to the edge of the deck. Where steel decking is used as a wall anchor system, the existing connections shall be subject to field verification and the new connections shall be subject to special inspection.

Exception: Existing cast-in-place shear anchors are allowed to be used as wall anchors if the tie element can be readily attached to the anchors, and if the engineer or architect can establish tension values for the existing anchors through the use of approved as-built plans or testing and through analysis showing that the bolts are capable of resisting the total shear load (including dead load) while being acted on by the maximum tension force caused by an earthquake. Criteria for analysis and testing shall be determined by the building official.

Reason: This proposal deletes an obsolete requirement. The ASD provision is no longer included in ASCE 7, and LRFD or strength design of steel elements no longer uses a 1.33 load duration factor. ASCE 7 Section 12.11.2.2 already provides special provisions for steel elements and for coordination with SDPWS.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The provisions are outdated and do not apply. Therefore this revision with not affect construction cost.
Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A401.2 Scope. The provisions of this chapter shall apply to all existing Occupancy Group R-1 and R-2 buildings of wood construction or portions thereof that contain residential occupancy and are assigned to Risk Category II, and where the structure has a soft, weak, or open-front wall line, and there exists one or more stories above.

Reason: The proposal clarifies the intended limitations of Chapter A4.

The words “shall” and “all” are deleted to correct the impression that adoption of Chapter A4 necessarily imposes a retroactive requirement. The purpose of Section A401.2 is to describe the buildings for which the chapter might be useful, not those that are required to comply. Charging language is found elsewhere in the IEBC, or is sometimes found in separate legislative mandates.

“Occupancy Group R-1 and R-2” is replaced with a more generic reference to R occupancy and a reference to Risk Category II because there is no reason why an R-4 facility (or even an R-3 dwelling) cannot use Chapter A4, as long as it is not a high hazard (RC III) or essential facility (RC IV).

The word “contain” is added to indicate that the building may have non-residential occupancy as well. Indeed, it is typically the presence of S or U occupancy (parking) in the first story that makes the building a candidate for Chapter A4. Many eligible buildings also have B or M occupancy in the critical story.

The phrase “or portions thereof” is deleted because it is unnecessary and potentially confusing.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal recognizes how Chapter A4 is currently used and the conditions to which it is meant to apply, some of which might be excluded by a misreading of the current provision.

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

CHAPTER A4
EARTHQUAKE RISK REDUCTION IN WOOD-FRAME RESIDENTIAL BUILDINGS WITH SOFT, WEAK OR OPEN-FRONT WALLS TARGET STORIES

[BS] A401.2 Scope. The provisions of this chapter shall apply to all existing Occupancy Group R-1 and R-2 buildings of wood construction or portions thereof where the structure has a soft, weak, or open front wall line, and there exists one or more stories above target story.

[BS] A402.1 Definitions. Notwithstanding the applicable definitions, symbols and notations in the building code, the following definitions shall apply for the purposes of this chapter:

Delete without substitution:

[BS] OPEN-FRONT WALL LINE. An exterior wall line, without vertical elements of the lateral force-resisting system, that requires tributary seismic forces to be resisted by diaphragm rotation or excessive cantilever beyond parallel lines of shear walls. Diaphragms that cantilever more than 25 percent of the distance between lines of lateral force-resisting elements from which the diaphragm cantilevers shall be considered to be excessive. Exterior exit balconies of 6 feet (1829 mm) or less in width shall not be considered excessive cantilevers.

[BS] SOFT WALL LINE. A wall line whose lateral stiffness is less than that required by story drift limitations or deformation compatibility requirements of this chapter. In lieu of analysis, a soft wall line may be defined as a wall line in a story where the story stiffness is less than 70 percent of the story above for the direction under consideration.

Add new definition as follows:

TARGET STORY. Either (1) a basement story or underfloor area that extends above grade at any point or (2) any story above grade, in which a significant portion of lateral or torsional story strength or story stiffness is provided by wood frame walls, and where the wall configuration of such basement, underfloor area, or story is substantially more vulnerable to earthquake damage than the wall configuration of the story above, except that a story is not a target story if it is the topmost story or if the difference in vulnerability is primarily due to the story above being a penthouse or an attic with a pitched roof.

Delete without substitution:

[BS] WEAK WALL LINE. A wall line in a story where the story strength is less than 80 percent of the story above in the direction under consideration.

[BS] A403.2 Scope of analysis. This chapter requires the alteration, repair, replacement or addition of structural elements and their connections to meet the strength and stiffness requirements herein. The lateral load-path analysis shall include the resisting elements and connections from the wood diaphragm immediately above any soft, weak or open front wall line at the top of the uppermost target story to the foundation soil interface or to the uppermost story of a podium structure comprised of steel, masonry, or concrete structural systems that supports the upper, wood-framed structure. Stories above the uppermost story with a soft, weak, or open front wall line target story shall be considered in the analysis but need not be modified. The lateral load-path analysis for added structural elements shall include evaluation of the allowable soil-bearing and lateral pressures in accordance with the building code. Where any portion of a building within the scope of this chapter is constructed on or into a slope steeper than one unit vertical in three units horizontal (33-percent slope), the lateral force-resisting system at and below the base level diaphragm shall be analyzed for the effects of concentrated lateral forces at the base caused by this hillside condition.

Exception: Where an open front, weak or soft wall line target story exists because of parking at the ground floor of a two-story building and the parking area is less than 20 percent of the ground floor area, then only the wall lines in the open, weak or soft directions of the enclosed critical direction around the adjacent parking area need comply with the provisions of this chapter.

[BS] A403.9.1 Gypsum or cement plaster products. Gypsum or cement plaster products shall not be used to provide lateral resistance in a soft or weak story or in a story with an open front wall line, whether or not new elements are added to mitigate the soft, weak or open-front condition, the strength required by Section A403.3 or the stiffness required by Section A403.4.
SECTION A404
PRESCRIPTIVE MEASURES FOR WEAK STORY

[BS] A404.1.1 Additional conditions. To qualify for these prescriptive measures, the following additional conditions need to be satisfied by the retrofitted structure:

1. Diaphragm aspect ratio $L/W$ is less than 0.67, where $W$ is the diaphragm dimension parallel to the target story critical direction and $L$ is the distance in the orthogonal direction between the perimeter wall line and the rear wall of the ground floor open area.
2. Minimum length of side shear walls = 20 feet (6096 mm).
3. Minimum length of rear shear wall = three-fourths of the total rear wall length.
4. Plan or vertical irregularities shall not be other than a soft, weak or open-front wall line, those associated with the target story.
5. Roofing weight less than or equal to 5 pounds per square foot (240 N/m²).
6. Aspect ratio of the full second floor diaphragm meets the requirements of the building code for new construction.

Reason: This proposal replaces three troublesome definitions unique to Chapter A4 with a more concise term already proven feasible in retrofit programs involving thousands of structures.

The proposal looks like it's big and makes a complicated change. It's actually straightforward and largely editorial – just an improvement in terminology. The three problematic definitions – open-front wall line, soft wall line, and weak wall line – are actually not that important to the substance of Chapter A4. Their purpose is merely to describe the buildings to which the chapter applies. Their job is to get you properly into the chapter, but they are not needed to get you out, as they are not used to measure compliance. Similarly, the definition and use of TARGET STORY proposed here is merely to identify candidate buildings. It will have no impact at all on the retrofit criteria or the resulting retrofit designs.

The three definitions represent attempts nearly 25 years ago to define the building type of interest. It's one every engineer in earthquake country knows by sight, but it's surprisingly hard to define. Most people know these simply as “soft story buildings,” borrowing a term from ASCE 7 and ASCE 41, and that quickly reveals the problem in Chapter A4. As ASCE 7 and FEMA P-807 (Seismic Evaluation and Retrofit of Multi-Unit Wood-Frame Buildings With Weak First Stories, 2012) make clear, the issue is a collapse-prone whole story, a combination of lateral and torsional vulnerability. Yet the current definitions in Chapter A4 relate only to individual wall lines. Further, the quantitative aspects of the definitions conflict with the retrofit criteria; it is possible to satisfy the Chapter A4 design criteria and still have a soft, weak, or open wall line by the current definitions.

Finally, by using words and concepts similar to those used in ASCE 7 to define certain irregularities and in ASCE 41 to identify certain deficiencies, these Chapter A4 definitions create confusion about how those standards apply (or don’t). Each of the definitions presents its own specific problems as well:

- **OPEN WALL LINE** is problematic because it is both under- and over-prescribed. Does “without vertical elements” mean there must be zero wall length for the wall line to be considered “open”? If there’s ample wall length, but it’s all stucco and gypsum board (not allowed for the retrofit by Section A403.9.1), does that count? If not, isn’t every wall line of a stucco building “open”? And what is the basis for the “25 percent” rule? Clearly this “definition” is relying on a lot of judgment, both from the code writers and the evaluating engineer. That’s ok, but let’s not pretend the definition is cut and dried.

- **SOFT WALL LINE** is confusingly defined two ways, first in absolute terms as a wall line that merely lacks the required stiffness, and second in relative terms by comparison of one story to the next (borrowing, but straying from the similar definitions in ASCE 7 and ASCE 41). The absolute definition is circular: a wall line is subject to Chapter A4 if it doesn’t satisfy Chapter A4, so you can’t know if the Chapter is necessary until you’ve done all the work. Since the definition is meant to establish (per Section A401.2) whether the chapter even applies, this tautology is not helpful. The relative definition is problematic first because it might not find the same buildings as the absolute definition but also because there is no consistent way to determine the stiffness of either story if, as Section A403.9.1 specifies, stucco and gypsum board are not to be considered. Many buildings that would benefit from Chapter A4 have nothing but stucco and gypsumboard, so is their upper story stiffness zero? If so, how can the first story stiffness be less than 70 percent of that? Finally, if a soft wall line is any wall line in a soft story, does that mean the wall lines normal to the soft direction are also deficient? Even if only wall lines in the critical direction are considered, is every wall line aligned in the weak direction considered a weak wall line that must be stiffened?

- **WEAK WALL LINE** uses only a relative definition, but it poses similar problems. What is the story strength if nonconforming materials must be ignored in accordance with Section A403.9.1? And which wall lines in a weak story are considered the weak ones that need to be strengthened through retrofit?

The solution to these problems is to use terminology that 1) does not twist similar terms from ASCE 7, 2) does not conflict with other provisions in the chapter, 3) allows a determination of Chapter applicability without conflicting with the design criteria, and 4) identifies the critical deficiency as a story issue, not a line issue.

The proposed definition of TARGET STORY satisfies these criteria. This definition (or similar) was developed to resolve issues that arose from applying Chapter A4 to a variety of vulnerable wood-frame residential buildings in California, and it is now in use by retrofit programs covering thousands of buildings in San Francisco, Berkeley, and Oakland. Features of the proposed new term:
By considering partial basements and unfinished underfloor areas, it accounts for common conditions of sloped sites.

It considers the whole story, not just individual wall lines, thus incorporating the lessons of FEMA P-807 and better matching the spirit of the ASCE 7 and ASCE 41 concepts without appropriating their terminology.

It is relative, comparing a lower story to the story above it. This is consistent with the intent of Chapter A4 to capture not just overstress or high drift, but likely concentrations of lateral deformation that lead to P-delta collapse.

It is based on vulnerable wood-frame construction, eliminating confusion about whether Chapter A4 should apply (it should not) to a building with an open front but with full-height CMU first story walls.

By using “significant” and “substantially,” the definition relies on the judgment of the evaluator or retrofit designer and on that of the code official. This is likely to be a point of concern for some, but it shouldn’t be, as there is ample precedent for use of these words. “Significant” or “substantial” appears in plenty of IBC and IEBC definitions (dangerous, Risk Category III, dry floodproofing, health hazard, live/work unit, thermosetting material) and provisions (IBC 408.8.4 re smoke-tight doors, IBC 909.10.2 re ducts, IBC 1106.6 re accessible parking, IEBC 1301.6.3 re fire doors, IEBC A106.1 re “significant cracking”, IEBC A304.2 and C103.1 re wood defects, etc.).

Further, the work contemplated by Chapter A4 is not do-it-yourself. It requires a design professional and a building permit, so it is appropriate for the chapter to rely on the judgment of professionals. In the case of “soft story” buildings, as noted above, there is ample reference material available without the need for a quantitative definition. Indeed, the current definitions were developed with certain Southern California building styles and configurations in mind, but they have proven inadequate for equally eligible buildings on sloped sites or of older styles and materials. The more generic definition of TARGET STORY is an improvement, even if it relies to a degree on engineering and code official judgment.

Finally, as noted above, the definition and use of TARGET STORY proposed here is merely to identify candidate buildings. It has no impact at all on the retrofit criteria or the resulting retrofit designs.

Ultimately, the proof is in the programs. Over the last five years, thousands of “soft story” evaluations and retrofits have been done using a definition of TARGET STORY essentially identical to the one proposed here. San Francisco screened over 6000 buildings on the basis of this judgmental definition with broad success and essentially 100% compliance.

To implement this improvement in terminology, the proposal would make the following changes:

- The chapter title, Section A401.2, A403.2, and A404.1.1 are changed to replace “soft, weak or open-front” with the new term, “target story.” Note that in Section A401.2, it is no longer necessary to reference the existence of a story above, as that condition is built into the new definition of TARGET STORY.

- Section A402.1: The three definitions are deleted, and the new definition is added.

- Section A403.2: The critical diaphragm is properly identified as the one “at the top of” the target story, not the one “immediately above” it. This is because the definition of STORY from the IBC includes the diaphragm above.

- Section A403.2 Exception and Section A404.1.1: The critical direction is properly described. With the current definitions, there is no “open, weak or soft direction” defined.

- Section A403.9.1: The proposal clarifies the intent of the section, regardless of terminology. The current chapter does not define a soft, weak, or open-front story; those terms are currently used only to define specific wall lines. Further, nothing in Chapter A4 requires the retrofit elements to be located along the specific wall lines identified as soft, weak, or open-front, so the limitation intended by this section should not apply only there.

- Section A404: The Section title is corrected. Even with the current definitions, Section A404 applies to more than just weak stories. Also note: “weak story” is not defined.

Note that Section A403.3, which refers to soft story and weak story irregularities, is not changed, because these correct references are to the terms defined in ASCE 7.

Cost Impact: The code change proposal will not increase or decrease the cost of construction Termination change and will not change the cost of construction.
2018 International Existing Building Code

[BS] A403.2 Scope of analysis. This chapter requires the alteration, repair, replacement or addition of structural elements and their connections to meet the strength and stiffness requirements herein. The lateral load-path analysis shall include the resisting elements and connections from the wood diaphragm immediately above any soft, weak or open-front wall lines to the foundation soil interface or to the uppermost story of a podium structure comprised of steel, masonry, or concrete structural systems that supports the upper, wood-framed structure. Stories above the uppermost story with a soft, weak, or open-front wall line shall be considered in the analysis but need not be modified. The lateral load-path analysis for added structural elements shall include evaluation of the allowable soil-bearing and lateral pressures in accordance with the building code. Where any portion of a building within the scope of this chapter is constructed on or into a slope steeper than one unit vertical in three units horizontal (33-percent slope), the lateral force-resisting system at and below the base level diaphragm shall be analyzed for the effects of concentrated lateral forces at the base caused by this hillside condition.

Exception: Where an open-front, weak or soft wall line exists because of parking at the ground floor of a two-story building and the parking area is less than 20 percent of the ground floor area, then only the wall lines in the open, weak or soft directions of the enclosed parking area need comply with the provisions of this chapter.

Reason: This proposal removes an unnecessary and obsolete exception. The exception is unnecessary because the buildings for which it was intended can often be shown to be acceptable (that is, not possessing any of Chapter A4’s targeted deficiencies) and are already afforded a simplified prescriptive solution in Section A404. The exception is obsolete because it improperly focuses on individual wall lines. As shown in FEMA P-807 (May 2012), Seismic Evaluation and Retrofit of Multi-Unit Wood-Frame Buildings With Weak First Stories, it is important to consider full-story behavior, including possible torsion, so any reduced retrofit scope should be justified by full-story calculations.

Finally, the “20 percent” criterion and the reference to an “enclosed parking area” are too vague. While originally conceived for buildings with parking only in one end bay, the provision as written could apply to any number of collapse-prone wall configurations for which the prescriptive exception might not be adequate.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The alternative solution allowed by the exception might reduce the design cost slightly, but it would not likely change the construction cost. In some cases, deleting the exception as proposed could even decrease the construction cost.

2018 International Existing Building Code
Delete without substitution:

[BS] GROUND FLOOR. Any floor whose elevation is immediately accessible from an adjacent grade by vehicles or pedestrians. The ground floor portion of the structure does not include any floor that is completely below adjacent grades.

Revise as follows:

[BS] A403.2 Scope of analysis. This chapter requires the alteration, repair, replacement or addition of structural elements and their connections to meet the strength and stiffness requirements herein. The lateral load-path analysis shall include the resisting elements and connections from the wood diaphragm immediately above any soft, weak or open-front wall lines to the foundation soil interface or to the uppermost story of a podium structure comprised of steel, masonry, or concrete structural systems that supports the upper, wood-framed structure. Stories above the uppermost story with a soft, weak, or open-front wall line shall be considered in the analysis but need not be modified. The lateral load-path analysis for added structural elements shall include evaluation of the allowable soil-bearing and lateral pressures in accordance with the building code. Where any portion of a building within the scope of this chapter is constructed on or into a slope steeper than one unit vertical in three units horizontal (33-percent slope), the lateral force-resisting system at and below the base level diaphragm shall be analyzed for the effects of concentrated lateral forces at the base caused by this hillside condition.

Exception: Where an open-front, weak or soft wall line exists because of parking at the ground floor of grade in a two-story building and the parking area is less than 20 percent of the ground floor area, then only the wall lines in the open, weak or soft directions of the enclosed parking area need comply with the provisions of this chapter.

[BS] A404.1 Limitation. These prescriptive measures shall apply only to two-story buildings and only where deemed appropriate by the code official. These prescriptive measures rely on rotation of the second floor diaphragm to distribute the seismic load between the side and rear walls of the ground a ground floor open area. In the absence of an existing floor diaphragm of wood structural panel or diagonal sheathing at the top of the first story, a new wood structural panel diaphragm of minimum thickness of \( \frac{1}{2} \) inch (19.1 mm) and with 10d common nails at 6 inches (152 mm) on center shall be applied.

Reason: This proposal is editorial. It removes an unnecessary term used confusingly in two places in Chapter A4, replacing it with clearer, more consistent wording that better conveys the intent. The current definition of GROUND FLOOR includes the phrase, “immediately accessible from an adjacent grade.” What does this mean? It has nothing to do with disabled access. Rather, it is meant to indicate typical grade- or street-level parking. But does it include a ramp? Does it include a main floor one or two steps up from grade? Does it include a floor that is at grade in one part of building but above or below grade in the rest of the building due to a sloped site? Fortunately, we need not resolve these questions because the term is used in only two places in Chapter A4, and the intent in both places can be better conveyed simply by using common words that can be understood in context, without a special definition.

In the exception to Section A403.2, the proposal replaces “at the ground floor” with “at grade.” This has a common meaning appropriate to the context, and it eliminates confusion over a needlessly complicated definition.

In Section A404.1, two small edits clarify the intent. The walls of interest are “around” the area of interest, and the floor diaphragm of interest is the one at the top of the critical story, not the “ground floor.” By eliminating the definition of GROUND FLOOR, the phrase “ground floor open area” in Section A404.1 and again in A404.1.1 can take on its common sense meaning as a portion of floor area, without undue focus on grade issues. Any complications due to sloping grade, etc. can be resolved by this section’s reliance on approval by the code official.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is an editorial clarification of intent which will not change cost of construction.

Proposal # 5714
Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A403.3 Design base shear and design parameters. The design base shear in a given direction shall be permitted to be 75 percent of the value required for similar new construction in accordance with the building code. The value of $R$ used in the design of the strengthening of any story shall not exceed the lowest value of $R$ used in the same direction at any story above. The system overstrength factor, $\Delta_0$, and the deflection amplification factor, $C_d$, shall be not less than the largest respective value corresponding to the $R$ factor being used in the direction under consideration.

Exceptions:

1. For structures assigned to Seismic Design Category B, values of $R$, $\Delta$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening.
2. For structures assigned to Seismic Design Category C or D, values of $R$, $\Delta$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme weak story irregularity defined as Type 5b in ASCE 7, Table 12.3-2.
3. For structures assigned to Seismic Design Category E, values of $R$, $\Delta$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme soft story, a weak story, or an extreme weak story irregularity defined, respectively, as Types 1b, 5a and 5b in ASCE 7, Table 12.3-2.
4. For retrofit systems involving different seismic force-resisting systems in the same direction within the same story, resisting elements are permitted to be designed using the least value of $R$ for the different structural systems found in each independent line of resistance if the following conditions are met: (1) The building is assigned to Risk Category I or II (2) The building height is no more than four stories above grade plane, and (3) the seismic force-resisting systems of the retrofitted building comprise only wood structural panel shear walls, steel moment-resisting frames, steel cantilever columns, and steel braced frames. Values for $C_d$ and $\Omega_0$ shall be consistent with the $R$ value used.

Reason: This proposal adds an exception that effectively allows different structural systems to be combined for retrofit without the restrictions that would apply in new construction.

The concept has been vetted with analytical studies by the Structural Engineers Association of Northern California Existing Buildings Committee and has been implemented as proposed here by retrofit programs affecting thousands of buildings in San Francisco, Berkeley, and Oakland, California.

This allows the effective use of typical retrofit schemes that involve different structural systems on different lines. Without this exception, a retrofit using an intermediate or ordinary steel frame along one line and wood structural panels elsewhere would be forced to over-design the wood elements. Studies by the SEAONC EBC showed that combining systems as proposed here would not result in worse performance.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal will decrease the cost of construction by allowing more efficient use of materials and avoiding unnecessary overdesign."
THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[B] A403.3 Design base shear and design parameters. The design base shear in a given direction shall be permitted to be 75 percent of the value required for similar new construction in accordance with the building code. The value of $R$ used in the design of the strengthening of any story shall not exceed the lowest value of $R$ used in the same direction at any story above. The system overstrength factor, $\Delta 0$, and the deflection amplification factor, $C_d$, shall not be less than the largest respective value corresponding to the $R$ factor being used in the direction under consideration.

Exceptions:

1. For structures assigned to Seismic Design Category B, values of $R$, $\Delta 0$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening.

2. For structures assigned to Seismic Design Category C or D, values of $R$, $\Delta 0$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme weak story irregularity defined as Type 5b in ASCE 7, Table 12.3-2.

3. For structures assigned to Seismic Design Category E, values of $R$, $\Delta 0$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme soft story, a weak story, or an extreme weak story irregularity defined, respectively, as Types 1b, 5a and 5b in ASCE 7, Table 12.3-2.

4. With reference to ASCE 7 Table 12.2-1, building height limitations on seismic force-resisting systems are not applicable where those systems are used only for retrofit to comply with the requirements of this Chapter.

Reason: This proposal adds an exception that allows typical retrofit solutions to be used without the restrictions that would apply in new construction. The concept has been vetted by the Structural Engineers Association of Northern California Existing Buildings Committee and has been implemented as proposed here by retrofit programs affecting thousands of buildings in San Francisco, Berkeley, and Oakland, California.

The proposed exception recognizes that height limits applicable when certain structural systems are used for a whole building should not apply when the same system is used only within a single story, which is the case with retrofit under Chapter A4. In this regard, the proposed exception is like current Exceptions 1 through 3, in that it decouples the design of the new retrofit system from non-conforming conditions in the existing structure.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal will decrease the cost of construction by waiving inapplicable limits and allowing more choices for retrofit systems.
EB157-19

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A403.3 Design base shear and design parameters. The design base shear in a given direction shall be permitted to be 75 percent of the value required for similar new construction in accordance with the building code. The value of $R$ used in the design of the strengthening of any story shall not exceed the lowest value of $R$ used in the same direction at any story above. The system overstrength factor, $\Delta \Omega$, and the deflection amplification factor, $C_d$, shall be not less than the largest respective value corresponding to the $R$ factor being used in the direction under consideration.

Exceptions:

1. For structures assigned to Seismic Design Category B, values of $R$, $\Delta \Omega$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening.
2. For structures assigned to Seismic Design Category C or D, values of $R$, $\Delta \Omega$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme weak story irregularity defined as Type 5b in ASCE 7, Table 12.3-2.
3. For structures assigned to Seismic Design Category E, values of $R$, $\Delta \Omega$, and $C_d$ shall be permitted to be based on the seismic force-resisting system being used to achieve the required strengthening, provided that when the strengthening is complete, the strengthened structure will not have an extreme soft story, a weak story, or an extreme weak story irregularity defined, respectively, as Types 1b, 5a and 5b in ASCE 7, Table 12.3-2.

[BS] A407.1 Structural observation, testing and inspection. Structural observation, in accordance with Section 1709.1704.6 of the International Building Code, shall be required for all structures in which seismic retrofit is being performed in accordance with this chapter. Structural observation shall include visual observation of work for conformance to the approved construction documents and confirmation of existing conditions assumed during design.

Structural testing and inspection for new construction materials shall be in accordance with the building code, except as modified by this chapter.

[BS] A406.3.2 Framing plan elements. The framing plan shall include the length, location and material of shear walls; the location and material of frames; references or details for the column-to-beam connectors, beam-to-wall connections and shear transfers at floor and roof diaphragms; and the required nailing and length for wall top plate splices.

[BS] A406.3.3 Shear wall schedule, notes and details. Shear walls shall have a referenced schedule on the plans that includes the correct shear wall capacity in pounds per foot (N/m); the required fastener type, length, gage and head size; and a complete specification for the sheathing material and its thickness. The schedule shall also show the required location of 3-inch (76 mm) nominal or two 2-inch (51 mm) nominal edge members; the spacing of shear transfer elements such as framing anchors or added sill plate nails; the required hold-down with its bolt, screw or nail sizes; and the dimensions, lumber grade and species of the attached framing member.

Notes shall show required edge distance for fasteners of structural wood panels and framing members; required flush nailing at the plywood surface; limits of mechanical penetrations; and the sill plate material assumed in the design. The limits of mechanical penetrations shall be detailed showing the maximum notching and drilled hole sizes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal is editorial only.

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code
Delete without substitution:

[BS] STORY STRENGTH. The total strength of all seismic-resisting elements sharing the same story shear in the direction under consideration.

[BS] WEAK WALL LINE. A wall line in a story where the story strength is less than 80 percent of the story above in the direction under consideration. For purposes of this definition, nonconforming structural materials shall not be considered.

Add new text as follows:

403.3.1 Expected story strength. Despite any other requirement of Section A403.3 or A403.4, the total expected strength of retrofit elements added to any story need not exceed 1.7 times the expected strength of the story immediately above in a two-story building, or 1.3 times the expected strength of the story immediately above in a three-story or taller building, as long as the retrofit elements are located symmetrically about the center of mass of the story above or so as to minimize torsion in the retrofitted story. Calculation of expected story strength and identification of irregularities in Section A403.3 shall be based on the expected strength of all wall lines, even if sheathed with nonconforming materials. The strength of a wall line shall be permitted to be reduced to account for inadequate load path or overturning resistance.

Revise as follows:

[BS] A403.9.1 Gypsum or cement plaster products. Gypsum or cement plaster products shall not be used to provide lateral resistance in a soft or weak story or in a story with an open-front wall line, whether or not new elements are added to mitigate the soft, weak or open-front condition. the strength required by Section A403.3 or the stiffness required by Section A403.4.

[BS] A406.2 Existing construction. The plans shall show existing diaphragm and shear wall sheathing and framing materials; fastener type and spacing; diaphragm and shear wall connections; continuity ties; collector elements; and the portion of the existing materials that needs verification during construction. If the cap allowed by Section A403.3.1 is used to limit the scope of retrofit, the foregoing information shall be shown for each retrofitted story and at least one story above the uppermost retrofitted story. If the cap allowed by Section A403.3.1 is not used, the foregoing information need only be shown for each retrofitted story and for the floor at the top of that story.

Reason: This proposal introduces a concept from FEMA P-807 (May 2012), Seismic Evaluation and Retrofit of Multi-Unit Wood-Frame Buildings With Weak First Stories. The concept is that over-strengthening of the critical story (typically the ground story) relative to the upper stories is wasteful and, in the worst cases, risks shifting the collapse mechanism to the less ductile upper stories. The concept has been confirmed in multiple analytical studies, has been endorsed by the Structural Engineers Association of Northern California Existing Buildings Committee, and has been implemented as proposed here by retrofit programs affecting thousands of buildings in San Francisco and Berkeley.

To apply the concept to IEBC Appendix A4, the required retrofit strength is capped relative to the calculated strength of the story above, as shown in proposed Section A403.3.1. The cap is optional.

To complete the proposal, the following additional changes are made:

- The unnecessary term STORY STRENGTH is deleted so as not to be confused with the “expected story strength” as used in new Section A403.3.1.
- In current Chapter A4, the term STORY STRENGTH is used only in the definition of WEAK WALL LINE, where it is actually not needed. Nevertheless, the proposal also clarifies this definition to preserve the current intent that nonconforming structural materials are not counted as “seismic-resisting elements” and are therefore not considered where the WEAK WALL LINE definition applies. The new capping provision, however, follows the FEMA P-807 requirement to consider all existing strength contributions.
- If the cap is applied, nonconforming materials must be considered. Therefore, Section A403.9.1, which prohibits nonconforming materials, is clarified to apply only to the basic strength and stiffness, exclusive of the capping provision.
- If the optional cap is applied, then because it relies on the existing conditions in the story above, those conditions should be documented as part of the project record, even though no retrofit is performed there. Section A406.2 is modified to make this documentation requirement.

Finally, note that the proposed text refers in several places to the “retrofitted story.” If the term “target story” is approved through a separate proposal, it would be preferable to replace all incidents of “retrofitted story” with “target story.”

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The cap is optional. If used, it could decrease the cost of construction.
THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Add new text as follows:

A403.3.1 Seismicity parameters, Site Class, and geologic hazards. For any site designated as Site Class E, the value of $F_s$ shall be taken as 1.3. Site-specific procedures are not required for compliance with this chapter. Mitigation of existing geologic site hazards such as liquefiable soil, fault rupture, or landslide is not required for compliance with this chapter.

Reason: This proposal clarifies the intended scope of Chapter A4. The proposed clarifications have been vetted by the Structural Engineers Association of Northern California Existing Buildings Committee (SEAONC EBC) and have been implemented as proposed here by retrofit programs affecting thousands of buildings in San Francisco, Berkeley, and Oakland, California.

The first two sentences simplify the application of IBC Section 1613.2 or ASCE 7 Section 11.4 to these retrofit projects, helping to keep them economically feasible. The value of $F_s = 1.3$, which is the default value for Site Class E in areas of high (but not highest or near-fault) seismicity, comes from a SEAONC EBC recommendation related to observed performance and recorded ground motions in the Loma Prieta earthquake. This value is allowed as a possibly conservative convenience, avoiding the need for expensive site-specific investigation (per ASCE 7 Table 11.4-1 and Section 11.4.8). Site-specific investigation remains an option, but is not required. This simplification is consistent in principle with the exceptions and waivers already provided in ASCE 7 Sections 11.4.8 and 20.3.1.

The site-specific ground motion procedures normally required by ASCE 7 Section 11.4.8 are waived for these retrofit projects. Many buildings eligible for Chapter A4 would be exempt from site response analysis by the exception to ASCE 7 Section 20.3.1.

The final proposed sentence clarifies that mitigation beyond the critical collapse-prone story is not intended by Chapter A4. Just as the chapter requires no retrofit above the critical story and no mitigation of nonstructural hazards, the proposal would waive geologic hazard mitigation that might be required for new construction or for more comprehensive triggered retrofits. Consistent with the limited scope of Chapter A4, these clarifications regarding geologic hazards are intended to keep Chapter A4 retrofits cost-effective.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

In some cases, it will decrease the cost of construction by avoiding the cost of investigation and mitigation. In some cases it will increase the cost of construction by defaulting to a possibly conservative value.
**EB160-19**

IEBC®: [BS] A403.7

**Proponent:** David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

### 2018 International Existing Building Code

**Delete without substitution:**

- [BS] A403.7 Collector elements. Collector elements shall be provided that can transfer the seismic forces originating in other portions of the building to the elements within the scope of Section A403.2 that provide resistance to those forces.

**Reason:** This proposal removes a provision that is both unnecessary and confusing. Section A403.7, while well-intended, is unnecessary because Section A403.1 already requires design in accordance with the IBC, and Section A403.6 already calls for ties and continuity that would include collectors where needed. Section A403.7 is also potentially confusing because it refers to “other portions of the building,” in conflict with Section A403.2, which clearly waives any modification above the uppermost retrofitted story.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This section is unnecessary as it is already required by the IBC. The proposal merely removes a redundant and confusing provision.
THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Delete and substitute as follows:

[B] A403.8 Horizontal diaphragms. The strength of an existing horizontal diaphragm sheathed with wood structural panels or diagonal sheathing need not be investigated unless the diaphragm is required to transfer lateral forces from vertical elements of the seismic force-resisting system above the diaphragm to elements below the diaphragm because of an offset in placement of the elements. Rotational effects shall be accounted for where asymmetric wall stiffness increases shear demands.

[B] A403.8 Floor diaphragms. Floor diaphragms within the scope of Section A403.2 shall be shown to have adequate strength at the following locations:

1. For straight lumber sheathed diaphragms without integral hardwood flooring: Throughout the diaphragm. The code official is authorized to waive the requirement where the condition occurs only in relatively small portions of each residential unit.
2. For other diaphragms: At locations where forces are transferred between the diaphragm and a new or strengthened vertical element of the seismic force-resisting system. Collector elements may be provided to distribute the transferred force over a greater length of diaphragm.

**Exception:** Where the existing vertical elements of the seismic force-resisting system are shown to comply with this chapter, diaphragms need not be evaluated.

**Reason:** This proposal clarifies the chapter’s intent regarding the need for diaphragm strengthening. The current provision focuses on locations where the walls above and below the diaphragm are offset from each other, but this can be read improperly to mean the entire diaphragm since a lack of stacked walls in the lower story is typically what makes a building a candidate for Chapter A4. Instead, the focus should be on proper force transfer between the critical diaphragm and the new or existing wall lines below. The proposal implements a recommendation by the Structural Engineers Association of Northern California Existing Buildings Committee that has already been adopted by retrofit programs affecting thousands of buildings in San Francisco, Berkeley, and Oakland, California.

The proposal recognizes that diaphragms are rarely the critical elements in these buildings. In many cases, the proposed requirement will require less work than the current provision. This is appropriate for the limited objective of Chapter A4.

The proposal also adds clarity by stating requirements for vulnerable diaphragm types that the current provision only implies.

Straight lumber sheathed diaphragms without integral hardwood flooring are weaker and more flexible than other diaphragm systems. Though there are no known collapses due to this condition, expected poor performance could compromise the building’s ability to meet even the limited objective of Chapter A4. Integral hardwood flooring – but not newer “floating” wood flooring – provides significant added strength and stiffness. Even in buildings with original hardwood flooring, some remodeled, carpeted, or tiled areas might have had the original wood flooring removed. Areas of the diaphragm that form a roof for the critical story (such as the portion of a garage that extends beyond the wall line above, or at a lightwell or building setback) are also unlikely to have hardwood flooring to supplement the straight sheathing. Small isolated areas without hardwood flooring are not expected to affect overall building performance, so the provision grants a waiver for these cases.

For less vulnerable diaphragm types, the provision requires a local check for each new or strengthened SFRS element but does not require an overall analysis of the full diaphragm. Diaphragm capacity need not be checked at existing vertical elements that are not strengthened because (except for straight lumber sheathed diaphragms) it is assumed that the unit capacities of the existing vertical elements and the diaphragm are comparable.

The exception waives any retrofit of the diaphragms if the existing walls and frames are already found adequate.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. In some cases, it could decrease the cost of construction as it may require less work than the current provisions.
This proposal clarifies the chapter’s design requirements.

Section A403.9: Since existing studs are presumed to carry existing gravity loads, the walls they frame must be considered bearing walls, as opposed to “building frame” systems. This affects the selection of seismic design coefficients $R$, $C$, and $\Omega$.

Section A403.9.1: The proposal clarifies the intent of the section, regardless of terminology, combined systems, etc. In particular, the chapter does not define a soft, weak, or open-front story; those terms are currently used only to define specific wall lines. Further, nothing in Chapter A4 requires the retrofit elements to be located along the specific wall lines identified as soft, weak, or open-front, so the limitation intended by this section should not apply only there.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is simply a clarification.
AISC 341-16: Seismic Provisions for Structural Steel Buildings

**Reason:** This proposal adds details for structural systems commonly used in Chapter A4 retrofits. The proposal implements a recommendation by the Structural Engineers Association of Northern California Existing Buildings Committee that has already been adopted by retrofit programs affecting thousands of buildings in San Francisco, Berkeley, and Oakland, California. The inverted moment frame (proposed Section A403.10.4) is a modification of traditional cantilevered column systems. Cantilevered column systems for new construction are normally assigned seismic design coefficients that severely limit their use. When used for retrofit of wood frame structures, however, the columns are less vulnerable to buckling failure because they carry no gravity load. SEAONC EBC has therefore recommended that these cantilever column systems, configured as upside-down moment frame bents (with concrete cross beams), should be allowed to be designed as moment frame systems.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal merely codifies typical practices already in use and shown to be feasible.

**Staff Analysis:** Note that AISC 341 is new to the IEBC but is currently referenced in the IBC.
EB164-19

IEBC®: SECTION A406, [BS] A406.1

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

Revise as follows:

SECTION A406
INFORMATION REQUIRED TO BE ON THE PLANS CONSTRUCTION DOCUMENTS

[BS] A406.1 General. The plans shall show all information necessary for plan review and for construction and, shall accurately reflect the results of the engineering investigation and design, and shall otherwise comply with all requirements established by the code official. The plans shall contain a note that states that this retrofit was designed in compliance with the criteria of this chapter.

Reason: This proposal revises the Chapter A4 administrative requirements to better align with IEBC Section 106 and with practices already adopted by the local building department.

The reference to “engineering investigation” is removed to avoid confusion (Chapter A4 does not explicitly require any such investigation) and because the “design” should already account for existing conditions, which are required to be documented per Section A406.2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal is consistent with Section 106 and is also consistent with local building department practices and therefore will not have an effect on cost.

Proposal # 5779
EB165-19

IEBC®: [BS] A407.1, A407.2 (New), A407.3 (New)

Proponent: David Bonowitz, representing Self (dbonowitz@att.net)

THIS CODE CHANGE WILL BE HEARD BY THE IBC STRUCTURAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Existing Building Code

[BS] A407.1 Structural observation, testing and inspection. Structural observation, in accordance with Section 1704.6 of the International Building Code, shall be required for all structures in which seismic retrofit is being performed in accordance with this chapter. Structural observation shall include visual observation of work for conformance to the approved construction documents and confirmation of existing conditions assumed during design. Structural testing and inspection for new construction materials shall be in accordance with the building code, except as modified by this chapter.

Add new text as follows:

A407.2 Contractor responsibility. Contractor responsibility shall be in accordance with Section 1704.4 of the International Building Code.

A407.3 Testing and inspection. Structural testing and inspection for new construction materials, submittals, reports, and certificates of compliance, shall be in accordance with Sections 1704 and 1705 of the International Building Code. Work done to comply with this chapter shall not be eligible for Exceptions 1, 2, or 3 of International Building Code Section 1704.2 or for the Exception to International Building Code Section 1705.12.2.

Reason: This proposal corrects a code reference and clarifies that typical quality assurance provisions from IBC Chapter 17 apply to Chapter A4 projects.

For clarity, the current provision is broken into three subsections. Regarding structural observation, the proposal corrects a mistaken IBC section number and clarifies that the requirement applies despite IBC waivers for buildings of certain heights or assigned to certain seismic design categories.

Regarding the contractor statement of responsibility, proposed Section A407.2 confirms that IBC section 1704.4 applies.

Regarding testing and inspection, proposed Section A407.2 clarifies the existing reference to “the building code” and disallows certain exemptions in IBC Chapter 17 that apply to new construction of a minor nature but should not apply to Chapter A4 retrofits.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal merely clarifies existing requirements. In rare cases, the cost of testing and inspection might increase slightly.

2018 International Energy Conservation Code

SECTION C101
SCOPE AND GENERAL REQUIREMENTS

C101.1 Title. This code shall be known as the Energy Conservation Code of [NAME OF JURISDICTION], and shall be cited as such. It is referred to herein as “this code.”

Revise as follows:

C101.2 Scope. This code applies to commercial buildings and the buildings’ sites and associated systems and equipment, structures, their associated sites, systems and equipment; and energy-using systems and equipment associated with sites considered areas of land under the control of a single owner or entity.

C101.3 Intent. This code shall regulate the design and construction of buildings, structures and sites for the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

C101.4.1 Mixed residential and commercial buildings, structures and sites. Where a building, structure or site includes both residential building uses and commercial building portions uses, each portion use group shall be separately considered and meet the applicable provisions of IECC—Commercial Provisions or IECC—Residential Provisions.

SECTION C202
GENERAL DEFINITIONS

BUILDING-SITE. A contiguous area of land that is under the ownership or control of one owner or entity.

Add new definition as follows:
SECTION C401
GENERAL

Revise as follows:

C401.1 Scope. The provisions in this chapter are applicable to commercial buildings, structures and their building-sites.

C401.2 Application. Commercial buildings, structures, and sites shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings, associated structures and sites shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The aggregate building, structure and site energy cost shall be equal to or less than 85 percent of the standard reference design building.

Add new text as follows:

C401.2.1 Application to structures and sites. Energy-using systems and equipment serving sites or structures, with or without a contiguous building, including site lighting; motors for pumps, fountain pumps and water moving equipment; and vertical transportation equipment, elevators and escalators, shall meet the applicable provisions of this code as described in Sections C403, C404, C405, C407 and C408.
SECTION R101 (IRC N1101)
SCOPE AND GENERAL REQUIREMENTS

R101.1 Title. This code shall be known as the Energy Conservation Code of [NAME OF JURISDICTION], and shall be cited as such. It is referred to herein as “this code.”

R101.2 Scope. This code applies to residential buildings and the building sites and associated systems and equipment, structures, their associated sites, systems and equipment; and energy-using systems and equipment associated with sites considered areas of land under the control of a single owner or entity.

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings, structures and sites for the effective use and conservation of energy over their useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

R101.4.1 Mixed residential and commercial buildings, structures and sites. Where a building, structure or site includes both residential building uses and commercial building portions uses, each portion use group shall be separately considered and meet the applicable provisions of the IECC—Commercial Provisions or IECC—Residential Provisions.

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

BUILDING SITE. A contiguous area of land that is under the ownership or control of one owner or entity.

Add new text as follows:

STRUCTURE. That which is built or constructed.

Revise as follows:

SECTION R401
GENERAL

R401.1 Scope. This chapter applies to residential buildings, structures and sites.
R401.2 (IRC N1101.13) Compliance. Projects Buildings, structures and sites shall comply with one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Add new text as follows:

R401.2.1 (IRC N1101.13.1) Application to structures and sites. Energy-using systems and equipment serving sites or structures, with or without a contiguous residential building, including site lighting; motors for pumps, fountain pumps and water moving equipment; and vertical transportation equipment, lifts, elevators and escalators, shall meet the applicable provisions of this code as described in Sections R403, R404, R405 and R406.

Revise as follows:

R401.2.1 R401.2.2 (IRC N1101.13.1 N1101.13.2) Tropical zone. Residential buildings, structures and sites in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level shall be deemed to be in compliance with this chapter provided that the following conditions are met:

1. Not more than one-half of the occupied space is air conditioned.
2. The occupied space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in conditioned spaces has a solar heat gain coefficient of less than or equal to 0.40, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section R404.
6. The exterior roof surface complies with one of the options in Table C402.3 or the roof or ceiling has insulation with an R-value of R-15 or greater. Where attics are present, attics above the insulation are vented and attics below the insulation are unvented.
7. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
8. Operable fenestration provides a ventilation area of not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building, at the structure, or in a conspicuous location on site. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall indicate the predominant R-values of insulation installed in or on ceilings, roofs, walls, foundation components such as slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces; U-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing performed on the building. Where there is more than one value for each component, the certificate shall indicate the value covering the largest area. The certificate shall indicate the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or
baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters.

**Reason:** There are areas outside of residential buildings where energy savings is possible by applying provisions currently in the IECC. Examples include lighting in parking lots that may or may not be directly associated with a commercial or residential building or lighting and equipment associated with a physical plant or pump, public or private parks a public or private campus or planned-unit-development. Imagine the additional and credible energy savings that could be acquired by expanding the scope and application of the residential provisions of the IECC, as such.

This proposal expands the scope and application of the residential provisions of the IECC to apply to energy-using systems in areas outside of the building structure itself. The proposal revises an existing term "BUILDING SITE" and introduces term, “STRUCTURE” utilized throughout the ICC Family of International Codes, to define those types of environments where the building may not enclose the extent of energy-using lighting, motor, pumping and vertical transportation systems and equipment addressed in the code as currently constituted. Also, a new provision is included in Chapter 4 [RE] "Application" to address structures and sites with or without buildings.

**Cost Impact:** The code change proposal will increase the cost of construction
While there will be a cost impact associated with this change when compared to current provisions, the change better positions the IECC to be clearer, more easily applied to structures and sites constructed without associated buildings, and more competitive than the 90.1 Standard or the Standard 90.2 alternatives on the issues.

Proposal # 5626
2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building. The shift of a load from on-peak period to off-peak shall be considered a part of the effective use of energy. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: The conservation of energy and its related cost are the foundation of the IECC. Since the cost of energy is time dependent, it makes sense to include the shift of a load from on-peak (most expensive per kw) to off-peak (least expensive) as a part of the effective use of energy. The definitions for load, on-peak and off peak are included in another code change proposal. Those proposed definitions are as follows:

- **LOAD** A portion of a system that consumes electric energy. The total electrical load of a building is the sum of all electricity consuming appliances, lights and systems, necessary for a building to function as designed.
- **ON-PEAK** The time of use during which the cost per kiloWatt-hour (kWh) is the highest and when the maximum generation resources are required to supply electricity to the customer.
- **OFF-PEAK** The time of use during which the cost per kiloWatt-hour (kWh) is the lowest and when generation resources are being underutilized.

The terms are found defined in on-line sources. These could be added to the proposal, if needed, at public comment stage.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change clarifies that load shifting is a part of the efficient use of energy and does not increase or decrease the cost of construction.
CE3-19 Part I

PART I — IECC: Part I: C101.3
IECC: Part II: R101.3(N1101.2)

PART II — IECC: R101.3 (IRC N1101.2)

Proponent: Joseph H. Cain, Solar Energy Industries Association (SEIA), representing Solar Energy Industries Association (SEIA) (JoeCainPE@gmail.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings and systems for the effective use and conservation of energy over the useful life of each building, including effective integration of energy efficiency measures, renewable energy systems, and energy storage systems. This code is intended to provide flexibility to permit the use of innovative approaches and techniques, including innovative approaches and techniques to achieve this objective, that achieve the most cost-effective means of compliance. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Proposal # 5487
CE3-19 Part II

IECC: R101.3 (IRC N1101.2)

Proponent: Joseph H. Cain, Solar Energy Industries Association (SEIA), representing Solar Energy Industries Association (SEIA) (JoeCainPE@gmail.com)

2018 International Energy Conservation Code

Revise as follows:

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings and systems for the effective use and conservation of energy over the useful life of each building, including effective integration of energy efficiency measures, renewable energy systems, and energy storage systems. This code is intended to provide flexibility to permit the use of innovative approaches and techniques, including innovative approaches and techniques to achieve this objective, that achieve the most cost-effective means of compliance. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: Renewable energy systems are an important component of the IECC, but the Intent section is presently silent on them. Effective integration of energy efficiency measures and renewable energy systems is critical to the future of energy codes and green/stretch/reach codes. At the time of submittal of these code change proposals, there are four states with 100% renewable energy goals: Hawaii, California, New Jersey, and New York. Other communities are committing to renewable energy goals through their own local renewable goals for power supply or for installation of renewable energy systems. As grid penetration of renewable energy systems increases, the need to energy storage systems -- mostly battery storage -- also increases. The Intent section of the IECC should evolve with our societal needs, as by the time this edition is in effect there will be even more renewable energy systems and battery storage systems.

Renewable energy is already explicitly included in the IECC in multiple locations, including, but not limited to: Section C202 Definitions; Section C407.3 Performance-based compliance; Appendix CA Solar Ready Zone; Section R406 Energy Rating Index; Appendix RA Solar Ready Provisions. The Intent section needs to catch up with the provisions within the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal represents a forward-thinking clarification of intent only, with no increase or decrease in cost of construction.

Proposal # 5695

CE3-19 Part II
CE4-19 Part I

PART I — IECC: Part I: Section C101.3
IECC: Part II: Section R101.3(N1101.2)

PART II — IECC: R101.3 (IRC N1101.2)

Proponent: William McHugh, The McHugh Company, representing Chicago Roofing Contractors Association (billmchugh-jr@att.net)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE, PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Proposal # 5330
Proponent: William McHugh, The McHugh Company, representing Chicago Roofing Contractors Association (billmchugh-jr@att.net)

2018 International Energy Conservation Code

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: The International Energy Conservation Code should regulate the minimum energy use requirements for a building throughout its life cycle. The IECC's Intent Section goes beyond minimum requirements and sets an unenforceable tone of 'effective use' and 'conservation of energy'. While these are noble goals, codes are to regulate minimum requirements. This proposal brings the section in line with the statements in the section above intent:
"The code is intended to be adopted as a legally enforceable document and it cannot be effective without adequate provisions for its administration and enforcement."

Adding words 'effective use' and 'conservation of energy', is not legally enforceable, confusing and brings opinion into the intent of the code. The intent sections should state that the code consists of minimum technical requirements as stated in the Energy Code sections - the 'provisions'. This proposal clarifies that the code is the minimum requirements, which is very clearly, legally enforceable.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is neutral when it comes to costs as it clarifies language and purpose of the code.
2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings for life safety along with the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Proposal # 5470
Proponent: Hope Medina, representing Self (hmedina@coloradocode.net)

2018 International Energy Conservation Code

Revise as follows:

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings for life safety along with the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: There is a misconception among some end users that the energy code is not a life safety code and this is not correct. The energy code either independently or working in conjunction with the other codes assist with several aspects of what is considered the main stream life safety. It assists with tight construction for fire, moisture diffusion within assemblies, and usability during extreme conditions. The intent should identify that this code is promoting life safety as it is stated in the other I-codes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change just acknowledges the life safety contribution.
CE6-19 Part I

PART I — IECC: Part I: Section C101.3
IECC: Part II: Section R101.3(N1101.2)

PART II — IECC: R101.3 (IRC N1101.2)

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants LLC, representing Self (dmeyers@ieccode.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings for the effective use and conservation of energy primarily for human comfort over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.
CE6-19 Part II

IECC: R101.3 (IRC N1101.2)

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants LLC, representing Self (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings for the effective use and conservation of energy primarily for human comfort over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: Indeed, it remains the intent of the IECC to apply to energy using systems designed primarily for human occupancy (i.e., thermal comfort, visual comfort and service hot-water comfort), and -- unless specifically noted to otherwise -- does not apply to energy using systems designed for commercial, business, educational or industrial processes. This interpretation of the IECC, the Code Council has offered in the past remains the same.

While there remain some direct and indirect inferences to commercial, business, educational or industrial process energy uses throughout the IECC, there exist no "explicit" or "all-inclusive" delineations as to energy end uses designed primarily for humans to live, sleep, eat, work, and play in and around residential buildings and residential building sites. Some examples of the direct and indirect inferences to commercial, business, educational or industrial process energy uses, include:

1. C402.1.1 Greenhouses.

3. C403.5 Economizers (Prescriptive), Exception 2; "... spaces designed to be humidified above 35°F (1.7°C) dewpoint temperature to satisfy "process needs."

4. C403.5.4.1 Design capacity; for:

   - "Systems primarily serving computer rooms ...",
   - "Systems where dehumidification requirements cannot be met using outdoor air temperatures of 50°F (10°C)
     dry bulb/45°F (7°C) wet bulb
   - and where 100 percent of the expected system cooling load at 45°F (7°C) dry bulb/40°F (4°C) wet bulb
     is met with evaporative water economizers."

5. C403.7.1 Demand control ventilation (Mandatory), Exception 5; Ventilation provided only for "process loads."

6. C403.10.1 or C403.10.2 for Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers.

7. C405.3.1 Total connected interior lighting power, Several exemptions:
• Lighting for photographic processes,
• Lighting for plant growth,
• Lighting for food warming, and
• Lighting in demonstration equipment for education,

8. C405.4.1 Total connected exterior lighting power, Several exemptions:

• Lighting associated with transportation,
• Temporary lighting, Industrial production, material handling and transportation lighting, and
• Theme element lighting in theme parks.

9. C406.7.1 Load fraction, Exception 2; "Waste heat recovery from ... building equipment, or process equipment."

10. C407.1 Scope; with reference to: "... receptacle loads and process loads," and energy used to recharge or refuel vehicles used for on-road and off-site transportation purposes.

Therefore, as was the case with the 2003 IECC, it is our opinion that neither the 2006 IECC nor its 2009, 2012, 2015, 2018 or forthcoming 2021 editions are intended to require greenhouses (heated/cooled primarily to preserve the commodity - plants) to meet the envelope provisions of the code.

Section 101.3 the 2006 IECC (our opinion) was inadvertently truncated by the Department of Energy in an effort to improve the utility and enforceability of the IECC vis-a-vis a 'MONSTROUS' scoping and technical content change (see EC48-03/04).

So then, without the proposed language, and interpreted literally, the IECC could indeed be read as limiting the amount of energy put into a blast furnace at a foundry, energy dedicated to civilian booster pumping stations and wastewater treatment facilities keeping our civilian water supply clean, energy to operate fermenting casks at a distillery, energy to run a conveyor at a packaging plant, or even the energy to modulate cabinet temperatures within telecommunication shelters dedicated to switching and signal receiving. However, this is simply not pragmatic and not the case.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification of the IECC Purpose and Scope. The resulting exclusions would mean the process energies assigned to domestic water pressure booster and sprinkler system pumping stations, wastewater treatment facilities, greenhouses, mechanical, service water-heating, electrical distribution or illumination systems or portion thereof conform to the provisions of this code as they relate to new construction without requiring the unaltered portion(s) of the existing system to comply with all of the requirements of this code. Additions, alterations or repairs shall not cause any one of the aforementioned existing systems to become unsafe, hazardous or overloaded.

[EB] 101.2.2.4 Change in occupancy. It shall be unlawful to make a change in the occupancy of any building structure which would result in an increase in demand for either fossil fuel or electrical energy supply unless such building or structure is made to comply with the requirements of this code or otherwise approved by the authority having jurisdiction. The code official shall certify that such building or structure meets the intent of the provisions of law governing building construction for the proposed new occupancy and that such change of occupancy does not result in any increase in demand for either fossil fuel or electrical energy supply or any hazard to the public health, safety or welfare.

101.2.3 Mixed occupancy. When a building houses more than one occupancy, each portion of the building shall conform to the requirements for the occupancy housed therein. Where minor accessory uses do not occupy more than 20 percent of the area of any floor of a building, the major use shall be considered the building occupancy. Buildings other than detached one- and two-family dwellings, townhouses, with a height of four or more stories above grade shall be considered commercial buildings for purposes of this code, regardless of the number of floors that are classified as residential occupancy.

101.3 Intent. The provisions of this code shall regulate the design of building envelopes for adequate thermal resistance, low air leakage and the design and selection of mechanical, electrical, service water-heating and illumination systems and equipment which will enable effective use of energy in the building construction. It is intended that these provisions provide flexibility to permit the use of innovative approaches and techniques to achieve effective utilization of energy. This code is not intended to abridge safety, health or environmental requirements under other applicable codes or ordinances.
and telecommunication shelters on residential property would be "excluded" from the scope and applicability of the IECC, without the need for explicitly articulated lists or exceptions. No change to stringency is proposed.

Proposal # 5637

2018 International Energy Conservation Code

Revise as follows:

C101.3 Intent. This code shall regulate the design and construction of buildings for the effective use of
conservation, production, and conservation storage of energy over the useful life of each building. This code is
intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this
objective. This code is not intended to abridge safety, health or environmental requirements contained in other
applicable codes or ordinances.

Proposal # 4692

CE7-19 Part I
Proponent: Steven Rosenstock, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

R101.3 (IRC N1101.2) Intent. This code shall regulate the design and construction of buildings for the effective use, conservation, production, and conservation storage of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

Reason: This proposal updates the intent to show that the IECC is now starting to regulate energy production and energy storage systems that are installed in new homes. This update is needed to account for trends in certain areas of the US. For example, Appendix RB contains requirements for solar-ready provisions installed on single-family homes and townhouses. In Section 406, the Energy Rating Index Compliance Alternative, renewable energy production can be used to obtain a better score. Therefore, the code is now starting to regulate renewable energy production systems that are installed in residential facilities.

Renewable energy systems are a form of energy production, not building energy use. The production of renewable energy does not conserve the amount of energy a building or end-use system or appliance will use. The intent of the code should be updated to account for the recent code changes.

In addition, in California’s Title 24, PV energy production systems are now required on new homes (with some exceptions). One of the options with this mandate is to include an on-site energy storage system in the home, as shown below:

From CA Title 24-2019:

"PV sizes from Equation 150.1-C may be reduced by 25 percent if installed in conjunction with a battery storage system. The battery storage system shall meet the qualification requirements specified in Joint Appendix JA12 and have a minimum capacity of 7.5 kWh."

Therefore, code officials will be enforcing the installation of on-site renewable energy production systems, along with the installation of on-site energy storage systems in some cases. This will in addition to enforcing the energy conservation requirements of the energy code.

Bibliography: California Energy Commission, "2019 BUILDING ENERGY EFFICIENCY STANDARDS FOR RESIDENTIAL AND NONRESIDENTIAL BUILDINGS", December 2018

Cost Impact: The code change proposal will not increase or decrease the cost of construction. In this proposal, the requirements in the code are not being changed. This proposal only clarifies the intent of the energy code to account for what is already occurring in certain building energy codes.
CE8-19 Part I

PART I — IECC: Part I:  Section C102.1
IECC: Part II:  Section R102.1

PART II — IECC: R102.1

Proponent: Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org)

THIS IS A 2 PART CODE CHANGE.  PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE.  PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE.  SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been approved. An alternative material, design or method of construction shall be approved where the code official finds that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code in quality, strength, effectiveness, fire resistance, durability and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond in writing, stating the reasons why the alternative was not approved. The requirements identified as "mandatory" in Chapter 4 shall be met.

Proposal # 5266
PropONENT: Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy
(dbresette@ase.org)

2018 International Energy Conservation Code

Revise as follows:

R102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code. The code official shall have the authority to approve an alternative material, design or method of construction upon application of the owner or the owner’s authorized agent. The code official shall first find that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code for strength, effectiveness, fire resistance, durability and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond to the applicant, in writing, stating the reasons why the alternative was not approved. The requirements identified as "mandatory" in Chapter 4 shall be met.

Reason: The purpose of this code change proposal is to help ensure that critical energy conservation measures are included in every new home, irrespective of the compliance path selected. Although Section R102.1.1/C102.1.1 of the IECC already requires that all above-code programs meet the "mandatory" measures of the code, there is currently no specific language that requires alternative materials, designs or methods of construction (in R102.1/C102.1) meet these important requirements. We believe that these alternative methods (for which there is very little direction provided in the code) should at a minimum require compliance with “mandatory” measures. Without such a requirement, we are concerned that this section could serve as a massive loophole for any code user that does not want to comply with one of the mandatory provisions.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The mandatory measures are already required by the code.

Staff Analysis: There is not a coordinate section in Chapter 11 of the IRC.
CE9-19 Part I

PART I — IECC: Part I: Section C102.1
IECC: Part II: Section R102.1

PART II — IECC: R102.1

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been approved. An alternative material, design or method of construction shall be approved where the code official finds that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code in quality, strength, effectiveness, fire resistance, durability, energy conservation and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond in writing, stating the reasons why the alternative was not approved.

Proposal # 5267

CE9-19 Part I
2018 International Energy Conservation Code

Revise as follows:

R102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code. The code official shall have the authority to approve an alternative material, design or method of construction upon application of the owner or the owner’s authorized agent. The code official shall first find that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code for strength, effectiveness, fire resistance, durability, energy conservation and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond to the applicant, in writing, stating the reasons why the alternative was not approved.

Reason: The purpose of this code change proposal is to help ensure that energy conservation will be considered in any request for approval of alternative materials, designs, or methods of construction. Although the current language of Section R102.1/C102.1 requires alternatives to be “not less than the equivalent” of the code requirement for quality, strength, effectiveness, fire resistance, durability, and safety, it is important that the energy conservation impact be considered as well – particularly in the International Energy Conservation Code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal merely clarifies that energy conservation must be considered in assessing alternatives to IECC requirements.

Staff Analysis: There is not a coordinate section in IRC Chapter 11, however IRC Section R104.11 covers the subject matter.
CE10-19 Part I

PART I — IECC: Part I: Section C102.1
IECC: Part II: Section R102.1

PART II — IECC: R102.1

Proponent: Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been approved. An approved alternative material, design or method of construction shall be approved where the code official finds, upon the written application of the owner or the owner's authorized agent. The code official shall first find that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code in quality, strength, effectiveness, fire resistance, durability and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond to the applicant, in writing, stating the reasons why the alternative was approved or was not approved.

Proposal # 5264

CE10-19 Part I
IECC: R102.1

Proponent: Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org)

2018 International Energy Conservation Code

Revise as follows:

R102.1 General. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been approved. The code official shall have the authority to approve an alternative material, design or method of construction upon the written application of the owner or the owner’s authorized agent. The code official shall first find that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code for strength, effectiveness, fire resistance, durability and safety. Where the alternative material, design or method of construction is not approved, the code official shall respond to the applicant, in writing, stating the reasons why the alternative was approved or was not approved.

Reason: The purpose of this code change proposal is to bring more consistency and transparency in code enforcement by helping to ensure that requests for recognition of alternative materials, designs, or methods of construction, and responses to these requests, be put in writing. This proposal does not change any substantive requirements of the code, but creates a record of the process for seeking alternatives to code requirements. The current code language already requires a written response in cases when a request is not approved, but does not specify what the code official should do when an alternative is approved. We do not believe that requiring a request and a response to be written in both cases will be onerous – in fact, we believe that many building code officials already require this. This proposal also synchronizes the language in the residential and commercial chapters. In the 2018 IECC, the language of C102.1 and R102.1 were updated, but with some differences between the two. We have proposed adopting the language from each section that provides the most clarity for code users.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. These changes do not modify any code requirements.

Staff Analysis: There is not a coordinate section in IRC Chapter 11, however IRC Section R104.11 covers the subject matter.
CE11-19 Part I

PART I — IECC: Part I: Section C102.1.1
IECC: Part II: Section R102.1.1(N1101.4)

PART II — IECC: R102.1.1 (IRC N1101.4)

Proponent: Shaunna Mozingo, City of Westminster, representing Self (smozingo@cityofwestminster.us)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C102.1.1 Above-code Alternate Energy Efficiency programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy efficiency program shall be considered to be in compliance with this code. The requirements identified as “mandatory” in Chapter 4 shall be met.

Proposal # 5434
R102.1.1 (IRC N1101.4) Above code Alternate Energy Efficiency programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy-efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy-efficiency program shall be considered to be in compliance with this code. The requirements identified as “mandatory” in Chapter 4 shall be met.

Reason: This section references national, state or local energy efficiency programs so the title should reflect that. It tells you in the wording that the program must exceed the code, it doesn't have to say it in the title as well.

Cost Impact: The code change proposal will not increase or decrease the cost of construction simple title change, no cost involved.
CE12-19 Part I

PART I — IECC: Part I: Section C102.1.1, Chapter 6CE
IECC: Part II: Section R102.1.1(N1101.4)

PART II — IECC: R102.1.1 (IRC N1101.4)

Proponent: Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C102.1.1 Above code programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy efficiency program shall be considered to be in compliance with this code where such buildings meet the requirements identified as "mandatory" in Chapter 4 shall be met, and the building thermal envelope is greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 502.3 and either Table 502.1.2 or 502.2(1) of the 2009 International Energy Conservation Code.

Add new text as follows:

IECC

International Code Council, Inc.
500 New Jersey Avenue NW 6th Floor
Washington DC 20001

Proposal # 5504
Proponent: Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

R102.1.1 (IRC N1101.4) Above code programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy-efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy-efficiency program shall be considered to be in compliance with this code where such buildings also meet the requirements identified as “mandatory” in Chapter 4 and the building thermal envelope is greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.

Reason: The purpose of this code change proposal is to establish a reasonable level of efficiency for the permanent thermal envelope in buildings constructed to “above code” programs. The IECC already requires that buildings constructed to the standards of an above-code program demonstrate compliance with the “mandatory” measures of the IECC; this proposal applies a minimum thermal envelope backstop similar to the one that applies to the Energy Rating Index in Section R406. If a minimum backstop is necessary for the ERI, it stands to reason that a minimum backstop would be even more valuable in an even less fully defined and potentially less rigorous “above code” program.

We have proposed the 2009 IECC in this proposal to maintain consistency with the current section R406, but we would also support referencing the 2012 IECC. (We have proposed updating the Section R406 backstop to the 2012 IECC in a separate proposal because we believe that as the IECC improves in efficiency, so also should the backstops and consumer protection provisions of the code.)

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Because the 2018 IECC is the baseline for any above-code program (and any cost impact statement), and because this backstop is far less stringent than the base code requirements, we do not expect any added construction costs as a result.
CE13-19 Part I

PART I — IECC: Part I: C103.2
IECC: Part II: R103.2 (N1101.5)

PART II — IECC: R103.2 (IRC N1101.5)

Proponent: Hope Medina, representing Self (hmedina@coloradocode.net)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code
Revise as follows:

C103.2 Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include, but are not limited to, the following as applicable:

1. Energy compliance path
2. Insulation materials and their R-values.
3. Fenestration U-factors and solar heat gain coefficients (SHGCs).
4. Area-weighted U-factor and solar heat gain coefficient (SHGC) calculations.
5. Mechanical system design criteria.
6. Mechanical and service water heating systems and equipment types, sizes and efficiencies.
7. Economizer description.
8. Equipment and system controls. Fan motor horsepower (hp) and controls.
9. Duct sealing, duct and pipe insulation and location.
10. Lighting fixture schedule with wattage and control narrative.
11. Location of daylight zones on floor plans.
12. Air sealing details.

Proposal # 5674

CE13-19 Part I
CE13-19 Part II

IECC: R103.2 (IRC N1101.5)

Proponent: Hope Medina, representing Self (hmedina@coloradocode.net)

2018 International Energy Conservation Code

Revise as follows:

R103.2 (IRC N1101.5) Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include the following as applicable:

1. Energy compliance path
2. Insulation materials and their $R$-values.
4. Area-weighted $U$-factor and solar heat gain coefficients (SHGC) calculations.
5. Mechanical system design criteria.
6. Mechanical and service water-heating systems and equipment types, sizes and efficiencies.
7. Equipment and system controls.
8. Duct sealing, duct and pipe insulation and location.

Reason: The plan examiner needs to know what energy compliance path the project was designed to, so they are able to determine if the project demonstrates compliance with the specific energy requirements. Often this information is not provided on the construction documents, and plans examiners are required to investigate which add time to the review process. This extension may be in the form of a review comment, or the time it takes to retrieve the information by email or phone. Providing this information at submittal will allow the plans examiner to review the plans to the intended energy compliance path the architect/designer chose for the project.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The reason it will not increase the cost is because essentially the architect or designer is just declaring which energy compliance path they chose for the project. It is usually a few words placed on the plans i.e. Prescriptive path or Performance path.
IECC: C103.2

Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

Revise as follows:

C103.2 Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include, but are not limited to, the following as applicable:

1. Insulation materials and their $R$-values.

2. Fenestration $U$-factors and solar heat gain coefficients (SHGCs).

3. Area-weighted $U$-factor and solar heat gain coefficient (SHGC) calculations.

4. Mechanical system design criteria.

5. Mechanical and service water heating systems and equipment types, sizes and efficiencies.

7. Equipment and system controls.

8. Fan motor horsepower (hp) and controls.

9. Duct sealing, duct and pipe insulation and location.

10. Lighting fixture schedule with wattage and control narrative.

11. Location of daylight zones on floor plans.

12. Air sealing details.

13. Heating and cooling load values for all systems, including documentation of heating and cooling load calculations, such as clear notation of the software or methodology used and key inputs and outputs for all zones, or the 25 largest capacity zones where a project has more than 25 zones.

14. Fan motor brake horsepower (bhp) required for fan motors 1 hp and larger

15. Provisions for HVAC system commissioning and balancing.

17. Others items as determined by the code official

**Reason:** 1. Why is the proposed code change needed?

A. Additional information is required in the 2018 IECC section C103.2 that is important for the ability of code officials to complete a proper review of plans. It is important to know and understand how the building is going to be built at time of permit application. Building it, and then submitting as built documents make absolutely no sense if you want the building to perform correctly and actually save energy. We would not build things such as automobiles, pacemakers and other things, without knowing ahead of time, exactly how to build them and how they interact with other components, so why do we think we should be able to do that with buildings. We need to do it right and have all the building information available ahead of time before the permit is issued.

B. The current list’s omission of two other specific construction document requirements, in the 2018 IECC, makes it likely that these will often be overlooked. These requirements are in section C408.2 Mechanical systems, and service water-heating systems commissioning and completion requirements, and section C403.8.2 Motor nameplate horsepower.

C. There are currently no other construction document requirements that will allow a plan reviewer to verify that the requirements of the following sections are met: C403.1.1 Calculation of heating and cooling loads, C403.3.1 Equipment sizing, and C408.3 Functional testing of lighting controls will be met.

d. All of the above items are needed and should be required to be submitted at time of plan review in order for the Code official to be able to do a proper plan review for a building that will perform in compliance with the code.

1. Why is the proposed code change a reasonable solution?

The only requirement that will require more than a very modest amount of additional design team effort is for heating and cooling load sizing, and its' documentation (item 5 in the list). These calculations are already required by code, so this just adds a requirement that a listing of results and documentation be provided. The amount of effort is kept reasonable for large buildings by limiting the documentation to the largest 25 zones for buildings with more than 25 zones.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

There is not cost that will be associated with this code change. These items are already being calculated and done as part of the building’s construction. All this change is doing is asking for the information at the time of permit application. It is important to design the building and then build to it instead of building it and then trying to make it work with the design. Providing this information up front assures that the building is designed properly and it the specs it will need to be built and inspected to.
2018 International Energy Conservation Code

Add new text as follows:

C103.2.2 Energy reference construction documents The requirements in this code shall be represented on the construction documents and specifically identification as energy reference sheets. Each trade has the option to locate their specific requirements within their section of the construction documents.
2018 International Energy Conservation Code

Add new text as follows:

**R103.2.2 (IRC N1101.5.2.2) Energy reference construction documents** The requirements in this code shall be represented on the construction documents and specifically identification as energy reference sheets. Each trade has the option to locate their specific requirements within their section of the construction documents.

**Reason:** The concept represented in this proposal is not a new concept. Construction plans will place the accessibility requirements and/or fire rated construction requirements on their own sheets with references to them throughout the construction plans. The intent of this proposal is similar to this concept. The intent of this proposal is to assist with gaining compliance with the requirements within this code. Often the requirements are placed intermittently throughout the plans and notes, which are then often inadvertently missed by plans examiners, builders, contractors, and inspectors because of the inconsistent locations they are placed. When placing all of the energy requirements within the construction plans on one or more sheets as needed will allow for the end users to be able to apply the energy requirements the architect, designers, and engineers have designed the project to. The proposal acknowledges that each trade may need to provide their respective energy requirements within their own section of the construction plans, but each trade is still required to provide the information on their sheets.

When everything is placed in one location it becomes easier to verify that all the requirements have been identified. When located in many places throughout the plans often plans examiners will write a review comment that will require the architect/designer to locate it on the plans, write a response to the comments, and take up valuable time for both the architect/designer and plans examiner. This may eliminate the needless review comments because one cannot find the information on the plans, and reduce the time needed to respond by the architect/designer. The idea is to reduce the time needed to get the project through the permitting process. This will allow for those involved with the construction process to install the energy requirements as designed and allow the inspector to inspect for them.

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal may increase the cost of construction on the front end with possible additional construction sheets. It may decrease the time in the permitting process which should decrease the cost of construction. It may also decrease the cost of construction for the builders when they are able to comply with the energy requirements and how the project was designed to by decreasing the number of reinspection. Which will also assist with the construction schedule.
Revise as follows:

C105.4 Approved third-party inspection agencies. The code official is authorized to accept reports of third-party inspection agencies not affiliated with the building design or construction, provided that such agencies are approved as to qualifications and reliability relevant to the building components and systems that they are inspecting.

Add new text as follows:

C105.4.1 Authorization of approved third-party inspection agency. When the code official authorizes the use of a third-party inspection agency for all or some aspects of code compliance inspections, the agency shall be authorized as a third-party extension of the code official to verify compliance.

C105.4.2 Approved third-party inspections agreement. The third-party inspection agency and the code official shall agree upon which compliance verification measures will be incorporated within each of their inspection processes. These measures shall include mandatory or other provisions required by the specific path of compliance chosen from C401.2.

C105.4.3 Approved third-party inspections reporting. The approved agency shall submit inspection reports to the code official and to the owner’s representative in accordance with Section 1704.2.4 of the International Building Code.
CE16-19 Part II

IECC: R105.4, R105.4.1 (New), R105.4.2 (New), R105.4.3 (New)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robbynrglogic.com); Shaunna Mozingo (sdmozingo@shaunnamozingo.com)

2018 International Energy Conservation Code

SECTION R105
INSPECTIONS

Revise as follows:

R105.4 Approved third-party inspection agencies. The code official is authorized to accept reports of third-party inspection agencies not affiliated with the building design or construction, provided that such agencies are approved as to qualifications and reliability relevant to the building components and systems that they are inspecting.

Add new text as follows:

R105.4.1 Authorization of approved third-party inspection agency. When the code official authorizes the use of a third-party inspection agency for all or some aspects of code compliance inspections, the agency shall be authorized as a third-party extension of the code official to verify compliance.

R105.4.2 Approved third-party inspections agreement. The third-party inspection agency and the code official shall agree upon which compliance verification measures will be incorporated within each of their inspection processes. These measures shall include mandatory or other provisions required by the specific path of compliance chosen from R401.2.

R105.4.3 Approved third-party inspections reporting. The approved agency shall submit inspection reports to the code official and to the owner’s representative in accordance with Section 1704.2.4 of the International Building Code.

Reason: In relation to the International Energy Conservation Code, third-party inspection agencies and building officials currently have a variety of ideas regarding what should constitute the work of the agency. For the ERI path, for example, many Raters understand that they must develop an ERI score, but do not fully understand their relationship to inspection of the mandatory requirements of the IECC. Jurisdictions having authority, are often either abdicating inspections or believe that Rater’s are looking at mandatory inspection items. In addition, the creation of a HERS Index score is different from the creation of an ERI score. A HERS Index score is an asset rating which allows for the derating of the R-value of poorly installed insulation in the energy model, as the objective is to benchmark the energy performance of the home on the HERS Index scale. An IECC ERI evaluation of the installation of Insulation does not allow for the deration of poorly installed insulation. If insulation is not installed in accordance with the manufactures instruction and the guidance given in table R402.4.1.1, then the installation should fail inspection and be reinstalled until it meets the mandatory requirement of the code. This disconnect in understanding is the genesis of this code change proposal. Building on the charging language of the approved inspection agency this proposal makes it clear that the inspection agency is third party. This proposal states that when acting as a third party the agency is actually acting as an extension of the jurisdiction having full delegated authority in order to better ensure there is no confusion between the project owner and their construction representatives on site. The most important part of this proposed language is the requirement to create a scope of work that defines the relationship between the third-party inspection agency and the authority having jurisdiction. Ultimately neither identity can rely on...
assumptions, and this proposal requires a level of coordination and dialog that is not overly burdensome yet extremely important.

As with the outlined special inspections of the IBC, the proposal ends by demonstrating to the project owner and their representative that defined inspection must occur either through the authority having jurisdiction or the approved third-party inspection agency and that the construction schedule can not proceed with subsequent phases of construction until all sequential inspections take place and pass. Lastly, the proposal seeks documentation that all approved inspections occurred and meet the intent of the code.

The clarity gained in the relationship between the authority having jurisdiction and the approved third-party inspection agency is crucial as we progress into more complicated and meaningful energy codes. Nationally, jurisdictions are losing experienced professionals to retirement. Consequently, more third-party inspection agencies are stepping in to fill the gap. These third-party inspection agencies tend to be solely focused on energy and are capable, and eager to work in the energy code compliance niche. They are filling a need for jurisdictions that are either under staffed or lack a desire to fully enforce the energy components of the code. This proposal clearly defines a path forward to meet the need by defining scope and responsibilities to better ensure compliance and thus achieve expected energy savings.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal does not increase cost but better allocates dollars currently being spent to ensure that the job being undertaken by approved third party inspection agencies truly meets the needs of the authority having jurisdiction.

**Staff Analysis:** There is not a coordinate section for R105.4 in Chapter 11 of the IRC.
CE17-19 Part I

PART I — IECC: Part I: C107.1.2
IECC: Part II: R107.1.2
IRC: Part III: R102.4.2

PART II — IECC: R107.1.2

PART III — IRC®: R102.4.2

Proponent: Craig Drumheller, National Association of Home Builders, representing National Association of Home Builders (CDrumheller@nahb.org)

This is a 3 part code change. Part I will be heard by the IECC-Commercial Committee. Part II will be heard by the IECC-Residential Committee. Part III will be heard by the IRC Building Committee. See the Tentative Hearing Order for these Committees.

2018 International Energy Conservation Code

Revise as follows:

C107.1.2 Provisions in referenced codes and standards. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code, the provisions of this code, as applicable, shall take precedence over the provisions in the referenced code or standard. Compliance materials, as cited in Section C101.5.1, shall incorporate the provisions of this code instead of the provisions in the referenced code or standard. Where proof of compliance is embedded in materials such as software, an affidavit attesting that software or other materials comply with this section shall be available.

Proposal # 5314

__________________________________
CE17-19 Part I
2018 International Energy Conservation Code

Revise as follows:

R107.1.2 Provisions in referenced codes and standards. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code, the provisions of this code, as applicable, shall take precedence over the provisions in the referenced code or standard. Compliance materials, as cited in Section R101.5.1, shall incorporate the provisions of this code instead of the provisions in the referenced code or standard. Where proof of compliance is embedded in materials such as software, an affidavit attesting that software or other materials comply with this section shall be available.
CE17-19 Part III

IRC®: R102.4.2

Proponent: Craig Drumheller, National Association of Home Builders, representing National Association of Home Builders (CDrumheller@nahb.org)

2018 International Residential Code

R102.4.2 Provisions in referenced codes and standards. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code, the provisions of this code, as applicable, shall take precedence over the provisions in the referenced code or standard. Compliance materials, as cited in Section N1101.3, shall incorporate the provisions of this code instead of the provisions in the referenced code or standard. Where proof of compliance is embedded in materials such as software, an affidavit attesting that software or other materials comply with this section shall be available.

Reason: There are supporting materials provided by third party developers which are referenced in the IECC. Often, these materials don't clearly state that they are fully compliant with the requirements of the code. This language change provides the AHJ the clear authority to ask for a written statement from the developer of the materials that they attest their product is compliant with the requirements of this code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change proposal may raise the cost for supporting materials that were non-compliant.

Proposal # 5750
**2018 International Energy Conservation Code**

**SECTION C202**

**GENERAL DEFINITIONS**

Add new definition as follows:

**ACCESSORY STRUCTURE.** A structure that is accessory to and incidental to that of the building and that is located on the same lot.

Proposal # 5510
Add new definition as follows:

ACCESSORY STRUCTURE. A structure that is incidental to that of the dwelling and that is located on the same lot.

Reason: The scope of this code states accessory structures are to comply with the requirements but does not provide a definition for what would be considered an accessory structure. This is similar to what is found in the International Residential Code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Staff Analysis: The purpose of providing definitions in I-codes is to define terms used in that specific I-code. The term “accessory structure” is not used in the IECC.
CE19-19 Part I

PART I — IECC: Part I: C202 (New)
IECC: Part II: R202 (N1101.6); Chapter 6RE (New)

PART II — IECC: R202 (IRC N1101.6), ASTM Chapter 6

Proponent: Donald Sivigny, State of Minnesota, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

AIR-IMPERMEABLE INSULATION. An Insulation that functions as an air barrier material having an air permeance equal to or less than 0.02L/s·m² at 75 Pa pressure differential as tested in accordance with ASTM E2178 or E283.

Proposal # 5365
CE19-19 Part II
IECC: R202 (IRC N1101.6), ASTM Chapter 6

Proponent: Donald Sivigny, State of Minnesota, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Revise as follows:

AIR-IMPERMEABLE INSULATION. An Insulation that functions as an air barrier material having an air permeance equal to or less than 0.02L/s= m² at 75 Pa pressure differential as tested in accordance with ASTM E2178 or E283.

Add new standard(s) as follows:

ASTM E2178-13 Standard Test Method for Air Permanence of Building Materials

Reason: This change combines and utilizes the language of the IRC and IECC definitions together for consistency, and accuracy as to what air impermeable insulation must meet to reduce both, air infiltration and exfiltration. This definition will create better enforcement and understanding of the code by providing a test standard. Because the definition in Section IRC Section N1101.6 is incomplete, this revision will allow the IRC Chapter 2 definition to cover Chapter 11 uses of the term. This will avoid confusion for both the builder and the code official.

If this proposal is successful, there will be no need to have a special definition just for Chapter 11. The definition can therefore be removed from Section N1101.6 to avoid duplication in the same document, and reduce confusion and document size and cost.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal simply adds the already required standard for air impermeable to the definitions of air impermeable insulation. There is not going to be any added costs or savings for clarifying the standard the insulation must meet.

Staff Analysis: The referenced standard, ASTM E2178-13, is currently referenced in the 2018 IECC-Commercial Provisions.

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

AIR, OUTDOOR. Air that is taken from the external atmosphere, and therefore not previously circulated through the HVAC system or the conditioned space.

Proposal # 5355

CE20-19 Part I
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

**AIR, OUTDOOR.** Air that is taken from the external atmosphere, and therefore not previously circulated through the HVAC system or the conditioned space.

**Reason:** There are three types of air addressed in buildings today. They include make-up air, combustion air and ventilation air. Of these three types of air, only ventilation air is addressed in the energy code. Make-up and combustion air are addressed in the Mechanical Code. Since the energy code does not have a definition of Outdoor Air, which is part of the ventilation air for a building, and since the term is used throughout the code, it is important to define what outdoor air is for clarity and use of the code to the code official and builder as well.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This change is simply defining one of the three airs associated with Buildings. It is good to define them so the user of the code understands the differences.
Proponent: jim edelson, representing New Buildings Institute (jim@newbuildings.org)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

BIOMASS GAS. A medium Btu gas containing methane and carbon dioxide, resulting from the action of microorganisms on organic materials such as a landfill.

BIOMASS WASTE. Organic non-fossil material of biological origin that is a byproduct or a discarded product. Biomass waste includes municipal solid waste from biogenic sources, landfill gas, sludge waste, agricultural crop byproducts, straw, and other biomass solids, liquids, and gases; but excludes wood and wood-derived fuels (including black liquor), biofuels feedstock, biodiesel, and fuel ethanol.

Revise as follows:

ON-SITE RENEWABLE ENERGY. Energy derived from solar radiation, wind, waves, tides, landfill biomass gas, biogas, biomass or the internal heat of waste or extracted from hot fluid or steam heated within the earth. The energy system providing on-site renewable energy shall be located on the project building site.

Reason: The existing definition in IECC dates to the 2012 IECC. It was proposed by the team of New Buildings Institute, US Depatment of Energy and American Institute of Architects. It was one clause in a comprehensive overhaul of the 2009 IECC. When it was written in 2010, it was the first time that renewable energy had been defined in an I-code, and it reflected a very early understanding of a much less mature industry. It has not been significantly revised since.

This proposal does indeed update the language by further refining biomass energy sources with terms that were not available at the time it was drafted in 2010. Revised language makes the proper distinction between geothermal energy sources and geothermal heat pumps. The revision also limits the biomass sources to those that meet specifications as waste products. There are many flavors of biomass energy, but this proposal ensures that virgin material of unknown origin is not used as a steady source of energy, which in the provisions of C406 is a trade-off for energy efficiency features of the building. The definitions of biomass gas and biomass waste are taken from the glossary of the Energy Information Administration.

This proposal does not restrict the geographic sourcing of the waste material, but it does ensure that the system converting the fuel is located on the building site.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal is a definition of renewable energy that will no have an impact on construction costs. The modification of the definition only applies only to the fuel used after occupancy.
CIRCULATING HOT WATER SYSTEM. A specifically designed water distribution system where one or more pumps are operated in the service hot water piping to circulate heated water from the water-heating equipment to the fixture supply and back to the water-heating equipment.

Revise as follows:

DEMAND RECIRCULATION WATER SYSTEM. A water distribution system having where one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe, pumps prime the service hot water piping with heated water upon a demand for hot water.
CE22-19 Part II

IECC: R202 (IRC N1101.6)

**Proponent:** David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

**2018 International Energy Conservation Code**

**SECTION R202 (IRC N1101.6)**

**GENERAL DEFINITIONS**

**CIRCULATING HOT WATER SYSTEM.** A specifically designed water distribution system where one or more pumps are operated in the service hot water piping to circulate heated water from the water-heating equipment to fixtures and back to the water-heating equipment.

**Revise as follows:**

**DEMAND RECIRCULATION WATER SYSTEM.** A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe. Pumps prime the service hot water piping with heated water upon demand for hot water.

**Reason:** This code change replicates the IPC definitions for "demand recirculation water systems definition". This provides consistency in the use of the term between the two codes. The "circulating hot water system" definition is already consistent, and is included here for reference and context.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at:

http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This change does not add to nor detract from the design and construction requirements.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

COMPLIANCE REPORT. Documents created to demonstrate compliance with the intent of the code for the purpose of obtaining the building permit and subsequently acquiring the certificate of occupancy.

Proposal # 4792
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

**COMPLIANCE REPORT** Documents created to demonstrate compliance with the intent of the code for the purpose of obtaining the building permit and subsequently acquiring the certificate of occupancy.
2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

COMPUTER ROOM. A room whose primary function is to house equipment for the processing and storage of electronic data and that has a design electronic data equipment power density of less than 20 watts per square foot (20 watts per 0.092 m²) of conditioned floor area or a connected design electronic data equipment load of less than 10 kW.

Reason: Why is the proposed code change needed?
Computer room spaces are designed with watt densities greatly exceeding 20 watts per square foot. This is an obvious error. In checking with the ASHRAE 90.1 definition, they identify greater than 20 watts per square foot.

Why is the proposed code change a reasonable solution? Because it corrects the metric parameters that define a space as a Computer Room.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This Change will not alter the cost of the Building as it is only a typographical correction.
Add new definition as follows:

**CORE AND SHELL.** The construction of the base building including but not limited to exterior structural walls, structural columns, roof structure including covering, floor structure, and exterior cladding. The defined thermal envelope including insulation in all required locations, the air barrier, and air sealing must be installed. Utilities are brought to the structure with limited installment within the structure. The required grading per the International Building Code and approved construction documents, and include a route to the building from the public way.

**Reason:** The intent of this definition is to define when a project is considered a core and shell, and what the requirements are. This will help to alleviate the discussion on who is responsible for which energy requirements at which stage of construction and build out.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This definition may shift the cost from one party of a project to another.

**Staff Analysis:** The purpose of providing definitions in I=Codes is to define terms using in that specific I-code. The term 'core and shell' is not used in the IECC.
Add new definition as follows:

**DIRECT DIGITAL CONTROL (DDC)** a type of control where controlled and monitored analog or binary data such as temperature and contact closures, are converted to digital format for manipulation and calculations by a digital computer or microprocessor, then converted back to analog or binary form to control physical devices.

Revise as follows:

**C403.6.1 Variable air volume and multiple-zone systems.** Supply air systems serving multiple zones shall be variable air volume (VAV) systems that have zone controls configured to reduce the volume of air that is reheated, recooled or mixed in each zone to one of the following:

1. Twenty percent of the zone design peak supply for systems with direct digital control (DDC) and 30 percent for other systems.
2. Systems with DDC where all of the following apply:
   2.1. The airflow rate in the deadband between heating and cooling does not exceed 20 percent of the zone design peak supply rate or higher allowed rates under Items 3, 4 and 5 of this section.
   2.2. The first stage of heating modulates the zone supply air temperature setpoint up to a maximum setpoint while the airflow is maintained at the deadband flow rate.
   2.3. The second stage of heating modulates the airflow rate from the deadband flow rate up to the heating maximum flow rate that is less than 50 percent of the zone design peak supply rate.
3. The outdoor airflow rate required to meet the minimum ventilation requirements of Chapter 4 of the International Mechanical Code.
4. Any higher rate that can be demonstrated to reduce overall system annual energy use by offsetting re-heat/recool energy losses through a reduction in outdoor air intake for the system as approved by the code official.
5. The airflow rate required to comply with applicable codes or accreditation standards such as pressure relationships or minimum air change rates.

**Exception:** The following individual zones or entire air distribution systems are exempted from the requirement for VAV control:

1. Zones or supply air systems where not less than 75 percent of the energy for reheating or for providing warm air in mixing systems is provided from a site-recovered, including condenser heat, or site-solar energy source.
2. Systems that prevent reheating, recooling, mixing or simultaneous supply of air that has been previously cooled, either mechanically or through the use of economizer systems, and air that has been previously mechanically heated.
**Reason:** Section C403.6.1 makes reference to "DDC" but nowhere in the code does it tell you what that is. There were a few different proposals for the 2018 IECC that covered DDC but the one that had the definition didn't pass so it left a hole here. We were hoping this would be handled by an errata but that never happened so we are bringing forth the definition as currently found in ASHRAE 90.1. We also added the italicized wording to the code section for clarity.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction clarification only

Proposal # 5427

CE26-19 Part I
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials
(don.sivigny@state.mn.us)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

GREENHOUSE. A structure or a thermally isolated area of a building that maintains a specialized sunlit environment exclusively used for, and essential to, the cultivation, protection or maintenance of plants. Greenhouse buildings or spaces have their own thermal envelope requirements that are independent of the rest of the conditioned spaces within the building.

Reason: 1. Why is the proposed code change needed?
It has been identified that an interpretation could be made that Section C403.12, Mechanical systems located outside of the building thermal environment could apply to greenhouse spaces, which is not the intent. This proposed change clearly identifies that greenhouses have their own building thermal envelopes, and therefore would not be defined as a space “outside the building thermal envelope.”

2. Why is the proposed code change a reasonable solution?
It easily clarifies an interpretation

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There is no Cost Change as this proposal only provides clarifying in a definition.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

GROUP R. Buildings or portions of buildings that contain any of the following occupancies as established in the International Building Code:

1. Group R-1.
2. Group R-2 where located more than three stories in height above grade plane.
3. Group R-4 where located more than three stories in height above grade plane.

RESIDENTIAL BUILDING. For this code, includes detached one- and two-family dwellings and multiple single-family dwellings (townhouses) and Group R-2, R-3 and R-4 buildings three stories or less in height above grade plane.
CE28-19 Part II
IECC: R202 (IRC N1101.6)

Proponent: Eric Makela, representing Northwest Energy Codes Group (ericM@newbuildings.org)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Revise as follows:

RESIDENTIAL BUILDING. For this code, includes detached one- and two-family dwellings and multiple single-family dwellings (townhouses) and Group R-2, R-3 and R-4 buildings three stories or less in height above grade plane.

Reason: Multifamily poses a conundrum for energy regulation. Generally, these buildings are constructed and renovated like commercial buildings, but used like residential buildings. As a result, the regulation of multifamily buildings has been split between the residential and the commercial codes. Multifamily buildings that are four stories and higher are considered high-rise and regulated by the commercial chapter of the International Energy Conservation Code (IECC). However, with their residential usage patterns and loads, they don't truly fit a commercial code with its focus on commercial loads and usage patterns. Multifamily buildings that are three stories or lower are regulated by the residential chapter of the IECC. However, with their larger size and higher occupant density, these low-rise multifamily buildings don't truly fit in a residential energy code with its focus on single family homes.

The result is energy regulation that does not adequately serve the multifamily market:

- Regulation by two different energy codes complicates both code compliance and code enforcement.
- Neither the Commercial nor the Residential code was crafted to address the unique characteristics of the multifamily building type.
- Advancing the energy code for multifamily is hindered by the necessity of pursuing changes simultaneously in two different codes, both of which are dominated by issues of building types other than multifamily.
- The presence of two different code baselines has made it very difficult to create above-code energy standards and efficiency programs that apply to all multifamily buildings.
- The IECC is delivering different energy outcomes for low-rise and high-rise multifamily buildings, even those that are very similar.

This proposal will solve these problems by simply placing all R-2 buildings (the occupancy that covers what is traditionally considered multifamily), regardless of height, under the commercial section of the code. Many small commercial buildings are constructed using the same construction methods, materials and equipment that are common in low-rise multifamily, so buildings like low-rise multifamily are already subject to the commercial requirements. This is the solution that has been chosen in Boulder, CO to solve this issue. A more comprehensive proposal that would have minimized the stringency impact of unifying high-rise and low-rise multifamily under one set of requirements was attempted in the 2018 code cycle, but ultimately was disapproved due to its complexity. This solution is far simpler and more straightforward, while still solving all the issues identified above.

If this proposal is adopted, the IECC will be improved substantially for its use with multifamily buildings:
- Both code compliance and code enforcement will be less complicated and therefore less costly
- The energy code will more directly address multifamily buildings
- A single code baseline will make it easier to create an above-code standard for Green standards, utility programs and recognition programs above-code standards, Green Standards, utility incentive programs, and other recognition efforts
- Multifamily code issues will no longer complicate the development of the Residential and Commercial codes*

* The entire process was informed by an energy analysis performed by the Pacific Northwest National Lab. Part of this analysis included comparing a 3-story building under the residential requirements to an otherwise identical 4-story building under the commercial requirements. The 3-story building had an EUI 7-10% higher than its 4-story counterpart. This result shows that the two sets of energy requirements in the code result in significantly different energy outcomes in multifamily buildings. This fact emphasizes the importance of this effort to bring coherence to the multifamily market.

**Cost Impact:** The code change proposal will increase the cost of construction
This proposal may increase the cost of construction since it will require low-rise MF buildings to meet commercial provisions of the code.

Proposal # 5785

CE28-19 Part II
CE29-19 Part I

PART I — IECC: Part I: C202
IECC: Part II: R202 (IRC N1101.6), R303.3 (IRC N1101.12), R403.5.1 (IRC N1103.5.1), R403.10.1 (IRC N1103.10.1)

PART II — IECC: R202 (IRC N1101.6), R303.3 (IRC N1101.12), R403.5.1 (IRC N1103.5.1), R403.10.1 (IRC N1103.10.1)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

NETWORKED GUESTROOM CONTROL SYSTEM. A control system, accessible with access from the front desk or other central location associated with a Group R-1 building, that is capable of identifying the occupancy status of each guestroom according to a timed schedule, and is capable of controlling HVAC in each hotel and motel guestroom separately.
CE29-19 Part II
IECC: R202 (IRC N1101.6), R303.3 (IRC N1101.12), R403.5.1 (IRC N1103.5.1), R403.10.1 (IRC N1103.10.1)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Revise as follows:

ACCESSIBLE. Admitting close approach as a result of not being guarded by locked doors, elevation or other effective means (see “Readily accessible”).

READILY ACCESSIBLE. Capable of being reached quickly for operation, renewal or inspection without requiring those to whom ready access is requisite to climb over or remove obstacles or to resort to portable ladders or access equipment (see “Accessible”).

READY ACCESS (TO) That which enables a device, appliance or equipment to be directly reached, without requiring the removal or movement of any panel, or similar obstruction.

ACCESS (TO) That which enables a device, appliance or equipment to be reached by ready access or by a means that first requires the removal or movement of a panel, or similar obstruction.

R303.3 (IRC N1101.12) Maintenance information. Maintenance instructions shall be furnished for equipment and systems that require preventive maintenance. Required regular maintenance actions shall be clearly stated and incorporated on a readily visible label. The label shall include the title or publication number for the operation and maintenance manual for that particular model and type of product.

R403.5.1 (IRC N1103.5.1) Heated water circulation and temperature maintenance systems (Mandatory). Heated water circulation systems shall be in accordance with Section R403.5.1.1. Heat trace temperature maintenance systems shall be in accordance with Section R403.5.1.2. Automatic controls, temperature sensors and pumps shall be accessible in a location with access. Manual controls shall be readily accessible in a location with ready access.

R403.10.1 (IRC N1103.10.1) Heaters. The electric power to heaters shall be controlled by a readily accessible on-off switch that is an integral part of the heater mounted on the exterior of the heater, or external to and within 3 feet (914 mm) of the heater in a location with ready access. Operation of such switch shall not change the setting of the heater thermostat. Such switches shall be in addition to a circuit breaker for the power to the heater. Gas-fired heaters shall not be equipped with continuously burning ignition pilots.

Reason: The reason for this change is that “accessible” is typically understood to be reachable by a person using a wheelchair. This is not the case in the sections shown to be revised. The revised language will clarify where the requirement is intended for inspection or repair.

Last cycle, CE137-16 Part 1 was approved by the commercial energy and disapproved by the residential energy. The IECC residential committee’s reason was “These terms are going to be too difficult to explain to contractors.”

The term ‘accessible’ is defined in the IBC and relates to elements and facilities that serve or have special accommodations for persons with mobility impairments. The IPC and IMC use the term “Access (to)” or “Ready
Access” for access to equipment which is proposed here for the IECC. A similar proposal was approved for the all the other codes.

One new definition in the Commercial Energy picked up “accessible”. That should be revised.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is an editorial issue with no code changes.

Proposal # 5784

CE29-19 Part II
2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

REMODEL. A change in a building’s interior or exterior from the original construction
Proponent: Hope Medina, representing Self (hmedina@coloradocode.net)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

REMODEL. A change in a building’s interior or exterior from the original construction

Staff Analysis: The purpose of providing definitions in I=Codes is to define terms using in that specific I-code. The term 'remodel' is not used in the IECC.

Proposal # 5813
CE31-19 Part I

PART I — IECC Part I: C202, C202(New)
IECC Part II R202(N1101.6)(New)

PART II — IECC: R202 (IRC N1101.6)

Proponent: jim edelson, New Buildings Institute, representing New Buildings Institute (jim@newbuildings.org)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

ON-SITE RENEWABLE ENERGY. Energy derived from solar radiation, wind, waves, tides, landfill gas, biogas, biomass or the internal heat of the earth. The energy system providing on-site renewable energy shall be located on the project site. renewable energy resources harvested at the building site.

Add new text as follows:

RENEWABLE ENERGY RESOURCES. Energy derived from solar radiation, wind, waves, tides, landfill gas, biogas, biomass or extracted from hot fluid or steam heated within the earth.
Add new definition as follows:

**ON-SITE RENEWABLE ENERGY.** Energy from renewable energy resources harvested at the building site.

**RENEWABLE ENERGY RESOURCES.** Energy derived from solar radiation, wind, waves, tides, landfill gas, biogas, biomass or extracted from hot fluid or steam heated within the earth.

**Reason:** There has been a definition of "onsite renewable energy" since 2012 in the commercial IECC. The term was first used in the IECC residential code in 2018, but no definition was included at that time. This proposal adds an updated version of that definition that is simultaneously being proposed for the commercial IECC. Some of the modifications are based on language that has been deliberated by an ASHRAE workgroup for over six months and is pending at ASHRAE 90.1 (at the time of this submittal). This proposal could establish consistency between IECC-residential, IECC-commercial, and ASHRAE 90.1, thereby simplifying compliance and enforcement for onsite renewable energy installations.

The listed energy resources in the definition are similar to those found in the current IECC definition with the exception of "extracted from hot fluid or steam heated within the earth". That proposed revision from the current definition makes the distinction between geothermal energy sources and geothermal heat pumps.

When these are accepted as definitions into this portion of the code, staff will be able to italicize the use of the terms such as in the definitions and the Footnote a to Table R406.4.

**Bibliography:** Addendum by to Standard 90.1-2016, Energy Standard for Buildings Except Low-Rise Residential Buildings; ASHRAE, January 2018. (pending at the time of submittal)

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is a definition of renewable energy that will not have an impact on construction costs.

Proposal # 4976
CE32-19 Part I

PART I — IECC Part I: C202
IECC Part II R202(N1101.6)

PART II — IECC: R202 (IRC N1101.6)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE.
PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER
FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

STANDARD REFERENCE DESIGN. A version of the proposed design that meets the minimum which has
been programmed to meet the the minimum prescriptive and mandatory requirements of this code. The
proposed design is measured against the standard reference design, and is used to determine the maximum
annual energy use requirement for compliance based on total building performance.

Proposal # 4892
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

STANDARD REFERENCE DESIGN. A version of the proposed design that meets the minimum which has been programmed to meet the minimum prescriptive and mandatory requirements of this code. The proposed design is measured against the standard reference design, and is used to determine the maximum annual energy use requirement for compliance based on total building performance.

Reason: There has been some degree of confusion in the meaning of a "Standard Reference Design". The revised definition may serve to clarify its intended meaning and its use.

Bibliography: IECC 2018

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a clarification which does not impact the current code requirement, nor its operation.

Proposal # 5759
Add new definition as follows:

**TENANT FINISH.** The first time a building or space that is completed for a specific use. This shall include but is not limited to the interior wall locations, wall coverings, flooring, plumbing fixtures, electrical fixtures, and mechanical installation.

**Reason:** The definition is to clarify when a project should be referred to as a tenant finish and when it should be referred to as a remodel. This will also clarify when certain requirements are required for each type of project.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

**Staff Analysis:** The purpose of providing definitions in I-codes is to define terms used in that specific I-code. The term “tenant finish” is not used in the IECC.
CE34-19 Part I

PART I — IECC: Part I: C202
IECC: Part II: R202 (N1101.6)

PART II — IECC: R202 (IRC N1101.6)

Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials
(don.sivigny@state.mn.us)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE.
PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER
FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

U-FACTOR (THERMAL TRANSMITTANCE). The coefficient of heat transmission (air to air) through a
building component or assembly, inclusive of the inside and outside air films, equal to the time rate of heat flow
per unit area and unit temperature difference between the warm side and cold side air films of the building
component or assembly (Btu/h • ft² • °F)[W/(m² • K)].

Proposal # 5353
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)

GENERAL DEFINITIONS

U-FACTOR (THERMAL TRANSMITTANCE). The coefficient of heat transmission (air to air) through a building component or assembly, inclusive of the inside and outside air films, equal to the time rate of heat flow per unit area and unit temperature difference between the warm side and cold side air films of the building component or assembly (Btu/h \cdot ft^2 \cdot °F) [W/(m^2 \cdot K)].

Reason: 1. Why is the proposed code change needed?
The definition as presented in the IECC is not correct or could be miss-interpreted. The U-Factor includes the inside and outside air films. Not including the results in an erroneous value.

2. Why is the proposed code change a reasonable solution?

It corrects or clarifies the definition of the U factor.

The U factor is a value that is used to show compliance with the insulation requirements, or used in calculations to show that building system perform in compliance with the code requirements. Not calculating it correctly could have an impact on verifying compliance with the code requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There will be no added or saved costs by clarifying the definition of U-factor. It is simply clarifying a definition that was not complete in the current Code.
CE35-19
IECC: C202

Proponent: Eric Makela, New Buildings Institute, representing Northwest Energy Codes Group
(ericM@newbuildings.org)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

WALL, ABOVE-GRADE. A wall associated with the building thermal envelope that is more than 15 percent above grade and is on the exterior of the building or any wall that is associated with the building thermal envelope that is not on the exterior of the building. This includes, but is not limited to, between-floor spandrels, peripheral edges of floors, roof and basement knee walls, dormer walls, gable end walls, walls enclosing a mansard roof and skylight shafts.

Reason: The current definition of above-grade wall is general and vague and allows for an interpretation that ignores the thermal performance of important building elements. For example, the existing definition is not clear that exposed floor edges are part of the above-grade wall. Depending on how the code is interpreted/enforced, this could leave this building element unregulated. This change to the definition clarifies it and closes this potential loophole. It is explicitly clear that the critical elements of a building that function as part of the wall component of the thermal envelope, even though they may not be thought of as walls, are regulated as walls. These elements will need to be either insulated to meet the above-grade wall requirements or be incorporated into weighted averages for the performance of the above-grade wall.

The language was drawn from the definition currently used in the WA state energy code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This modification clarifies the code and should not increase the cost of construction.

2018 International Energy Conservation Code

SECTION C301
CLIMATE ZONES

C301.1 General. Climate zones from Figure C301.1 or Table C301.1 shall be used for determining the applicable requirements from Chapter 4. Locations not indicated in Table C301.1 shall be assigned a climate zone in accordance with Section C301.3.

Revise as follows:
FIGURE C301.1

The top map shows the United States divided into zones based on climate: Dry (B), Moist (A), and Warm-Humid (below the white line). The zone labels include regions such as Alaska, northwest Arctic, Southeast Fairbanks, Wade Hampton, and Yukon-Koyukuk.

The bottom map provides a detailed regional climate division, with specific zones like Zone 6A Extremely Hot Humid, Zone 6B Extremely Hot Dry, and Zone 6A Mixed Humid.

C301.3 International-climate zones: Climate Zone Definitions The climate zone for any location outside the
United States shall be determined by applying Table C301.3(1) and then Table C301.3(2). To determine the climate zones for locations not listed in this code, use the following information to determine climatezone numbers and letters.

Determine the thermal climate zone, 0–8, from Table C301.3(1) using the heating and cooling degree-days for the location. Determine the moisture zone (Marine, Dry or Humid):

a. If monthly average temperature and precipitation data are available, use the Marine, Dry, and Humid definitions below to determine the moisture zone (C, B, or A).

b. If annual average temperature information (including degree-days) and annual precipitation (i.e. annual mean) are available, use the following to determine the moisture zone:

1. If thermal climate zone is 3 and CDD50°F ≤ 4500 (CDD10°C ≤ 2500), climate zone is Marine (3C).

2. If thermal climate zone is 4 and CDD50°F ≤ 2700 (CDD10°C ≤ 1500), climate zone is Marine (4C).

3. If thermal climate zone is 5 and CDD50°F ≤ 1800 (CDD10°C ≤ 1000), climate zone is Marine (5C).

Use the third criteria below for determining the Dry/Humid threshold if not Marine (C).

c. If only degree-day information is available, use the following to determine the moisture zone:

1. If thermal climate zone is 3 and CDD50°F ≤ 4500 (CDD10°C ≤ 2500), climate zone is Marine (3C).

2. If thermal climate zone is 4 and CDD50°F ≤ 2700 (CDD10°C ≤ 1500), climate zone is Marine (4C).

3. If thermal climate zone is 5 and CDD50°F ≤ 1800 (CDD10°C ≤ 1000), climate zone is Marine (5C).

It is not possible to assign Dry/Humid splits in this case. Marine (C) Zone Definition—Locations meeting all four of the following criteria:

a. Mean temperature of coldest month between 27°F (–3°C) and 65°F (18°C)

b. Warmest month mean < 72°F (22°C)

c. At least four months with mean temperatures over 50°F (10°C)

d. Dry season in summer. The month with the heaviest precipitation in the cold season has at least three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.

Dry (B) Definition—Locations meeting the following criteria:

a. Not Marine (C)

b. If 70% or more of the precipitation, P, occurs during the high sun period, then the dry/humid threshold is: 

\[ P < 0.44 \times (T - 7) \times (1 - P) \quad \text{(T - 7) SI} \]

\[ P < 20.0 \times (T + 14) \quad \text{(SI)} \]
c. If between 30% and 70% of the precipitation, \( P \), occurs during the high sun period, then the dry/humid threshold is: \( P < 0.44 \times (T - 19.5) \) (I-P) \( P < 20.0 \times (T + 7) \) (SI)

d. If 30% or less of the precipitation, \( P \), occurs during the high sun period, then the dry/humid threshold is: \( P < 0.44 \times (T - 32) \) (I-P) \( P < 20 \times T \) (SI)

where:

\[ P = \text{annual precipitation, in. (mm)} \]
\[ T = \text{annual mean temperature, °F (°C)} \]

Summer or = April through September in the high sun Northern Hemisphere and October period through March in the Southern Hemisphere. Winter or = October through March in the Northern cold season Hemisphere and April through September in the Southern Hemisphere. Humid (A) Definition—Locations that are not Marine (C) and not Dry (B)

Delete without substitution:

**TABLE C301.3(1)**
INTERNATIONAL CLIMATE ZONE DEFINITIONS

**MAJOR CLIMATE TYPE DEFINITIONS**

**Marine (C) Definition**—Locations meeting all four criteria:
1. Mean temperature of coldest month between -3°C (27°F) and 18°C (65°F).
2. Warmest month mean < 22°C (72°F).
3. At least four months with mean temperatures over 10°C (50°F).
4. Dry season in summer. The month with the heaviest precipitation in the cold season has at least three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.

**Dry (B) Definition**—Locations meeting the following criteria:

Not marine and \( P_{a} < 0.44 \times (TF - 19.5) \) (\( P_{a} < 2.0 \times (TC + 7) \) in SI units)

where:

\[ P_{a} = \text{Annual precipitation in inches (cm)} \]
\[ T = \text{Annual mean temperature in °F (°C)} \]

**Moist (A) Definition**—Locations that are not marine and not dry.

**Warm-humid Definition**—Moist (A) locations where either of the following wet-bulb temperature conditions shall occur during the warmest six consecutive months of the year:
1. 67°F (19.4°C) or higher for 3,000 or more hours; or
2. 73°F (22.8°C) or higher for 1,500 or more hours.

For SI: °C = ((°F) -32)/1.8, 1 inch = 2.54 cm.

</table>
For SI: °C = [(°F)-32]/1.8.

**C301.4 Tropical climate zone.** The tropical *climate zone* shall be defined as:

1. Hawaii, Puerto Rico, Guam, American Samoa, U.S. Virgin Islands, Commonwealth of Northern Mariana Islands; and
2. Islands in the area between the Tropic of Cancer and the Tropic of Capricorn.
2018 International Energy Conservation Code

SECTION R301
CLIMATE ZONES

R301.1 (IRC N1101.7) General. Climate zones from Figure R301.1 or Table R301.1 shall be used for determining the applicable requirements from Chapter 4. Locations not indicated in Table R301.1 shall be assigned a climate zone in accordance with Section R301.3.

Revise as follows:

**Notes:**
- Districts in bold indicate counties in the same state.
- Counties marked with an asterisk (*) are additional to the main districts.
- Some counties are marked with a second asterisk (**) indicating they are part of a larger region.
- Districts are listed in alphabetical order by state and then by county within the state.
- The table includes major cities associated with each district.
- The table also notes counties within states that are not listed in the main districts.

**R301.3 (IRC N1101.7.2) International climate zones. Climate zone definitions.** The climate zone for any location outside the United States shall be determined by applying Table R301.3(1) and then Table R301.3(2). To determine the climate zones for locations not listed in this code, use the following information to determine climate zone numbers and letters.

Determine the thermal climate zone, 0–8, from Table R301.3(1) using the heating and cooling degree-days for the location. Determine the moisture zone (Marine, Dry or Humid):

a. If monthly average temperature and precipitation data are available, use the Marine, Dry, and Humid definitions below to determine the moisture zone (C, B, or A).

b. If annual average temperature information (including degree-days) and annual precipitation (i.e. annual mean) are available, use the following to determine the moisture zone:

1. If thermal climate zone is 3 and CDD50°F ≤ 4500(CDD10°C ≤2500), climate zone is Marine (3C).

2. If thermal climate zone is 4 and CDD50°F ≤ 2700(CDD10°C ≤ 1500), climate zone is Marine (4C).

3. If thermal climate zone is 5 and CDD50°F ≤ 1800(CDD10°C ≤ 1000), climate zone is Marine (5C).

Use the third criteria below for determining the Dry/Humid threshold if not Marine (C).

c. If only degree-day information is available, use the following to determine the moisture zone:
1. If thermal climate zone is 3 and CDD50°F ≤ 4500 (CDD10°C ≤ 2500), climate zone is Marine (3C).

2. If thermal climate zone is 4 and CDD50°F ≤ 2700 (CDD10°C ≤ 1500), climate zone is Marine (4C).

3. If thermal climate zone is 5 and CDD50°F ≤ 1800 (CDD10°C ≤ 1000), climate zone is Marine (5C).

It is not possible to assign Dry/Humid splits in this case.

Marine (C) Zone Definition—Locations meeting all four of the following criteria:

a. Mean temperature of coldest month between 27°F (–3°C) and 65°F (18°C)

b. Warmest month mean < 72°F (22°C)

c. At least four months with mean temperatures over 50°F (10°C)

d. Dry season in summer. The month with the heaviest precipitation in the cold season has at least three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.

Dry (B) Definition—Locations meeting the following criteria:

a. Not Marine (C)

b. If 70% or more of the precipitation, P, occurs during the high sun period, then the dry/humid threshold is: P < 0.44 \times (T – 7) (I-P)
P < 20.0 \times (T + 14) (SI)

c. If between 30% and 70% of the precipitation, P, occurs during the high sun period, then the dry/humid threshold is: P < 0.44 \times (T – 19.5) (I-P)
P < 20.0 \times (T + 7) (SI)

d. If 30% or less of the precipitation, P, occurs during the high sun period, then the dry/humid threshold is: P < 0.44 \times (T – 32) (I-P)
P < 20 \times T (SI)

where: P = annual precipitation, in. (mm). T = annual mean temperature, °F (°C). Summer or = April through September in the high sun Northern Hemisphere and October period through March in the Southern Hemisphere. Winter or = October through March in the Northern cold season Hemisphere and April through September in the Southern Hemisphere.

Humid (A) Definition—Locations that are not Marine (C) and not Dry.

Revise as follows:
**Marine (C) Definition**—Locations meeting all four criteria:

1. Mean temperature of coldest month between -3°C (27°F) and 18°C (65°F).
2. Warmest month mean < 22°C (72°F).
3. Not fewer than four months with mean temperatures over 10°C (50°F).
4. Dry season in summer. The month with the heaviest precipitation in the cold season has not less than three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.

**Dry (B) Definition**—Locations meeting the following criteria:

- Not marine and \( P < 0.44 \times (T_F - 19.5) \) \[ \text{or} \] \( P < 2.0 \times (T_C + 7) \) in SI units\]

\[ P = \text{Annual precipitation in inches (cm)} \]

\[ T = \text{Annual mean temperature in °F (°C)} \]

**Moist (A) Definition**—Locations that are not marine and not dry.

**Warm-humid Definition**—Moist (A) locations where either of the following wet-bulb temperature conditions shall occur during the warmest six consecutive months of the year:

1. 67°F (19.4°C) or higher for 3,000 or more hours.
2. 73°F (22.8°C) or higher for 1,500 or more hours.

For SI: °C = [(°F) - 32]/1.8, 1 inch = 2.54 cm.

### TABLE R301.3(2) [IRC N1101.7.2(2.1)]

**INTERNATIONAL CLIMATE ZONE DEFINITIONS**

</tbody>
</table>

For SI: °C = [(°F) - 32]/1.8.
R301.4 (IRC N1101.8) Tropical climate zone. The tropical *climate zone* shall be defined as:

1. Hawaii, Puerto Rico, Guam, American Samoa, U.S. Virgin Islands, Commonwealth of Northern Mariana Islands; and
2. Islands in the area between the Tropic of Cancer and the Tropic of Capricorn.

**Reason:**

Currently approximately 10% of the counties across the US have different different climate zones under the IECC and ASHRAE 90.1, ASHRAE 90.2, and the IgCC. This proposal updates the climate zones to correspond with the release of ASHRAE Standard 169-2013, which is referenced in both the 2018 IgCC and ASHRAE 90.1 and ASHRAE 90.2 Approximately 10% of the counties in the United States have a change in Climate Zone designation due to this change. ICC has a licensing agreement with ASHRAE to include the climate zone map, definitions and tables for consistency with ASHRAE Standard 169-2013.

This modification includes:

- The U.S. map as Figure R301.1 and U.S. county tables as Table R301.1 to be used in determining the climate zone for locations within the U.S.
- Updating county climate zone designations in Tables C301.1 and R301.1
- Updating the information in Tables C301.3(1) and R301.3(1) with an updated Climate Zone Definition, replacing these tables with text in Sections C301.3 and R301.3.
- Updating Tables C301.3(2) and R301.3(2) to include Climate Zone 0, and modify climate zones 1-4 for consistency across the IECC, IgCC and ASHRAE 90.1.

Climate Zone 0 is a subset of the previous Climate Zone 1. Whereas the previous CZ 1 was all locations with more than 9,000 Cooling Degree Days, Climate Zone 1 now "tops out" at 10,800 Cooling Degree Days, and Climate Zone 0 is for those locations with more than 10,800 Cooling Degree Days. Cities in Climate Zone 0 include very hot locations such as Mumbai (Bombay), Jakarta and Abu Dhabi. There are no cities in the United States in Climate Zone 0; Miami and the islands of Hawaii are in Climate Zone 1.

The separation of Climate Zones 0 and 1 allows separate criteria for IECC to be developed that are more specific to the very hot regions with Climate Zone 0.

Because Climate Zone 0 is a subset of the previous Climate Zone 1, and the code does not currently have any criteria specific to climate zone 0, the following are typical editorial change that will result from the addition of Climate Zone 0.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IGCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Proposal # 5824

CE36-19 Part II
2018 International Energy Conservation Code

C303.1 Identification. Materials, systems, and equipment shall be identified in a manner that will allow a determination of compliance with the applicable provisions of this code.

1. Listed for the intended use;

2. Installed in accordance with the manufacturer's installation instructions; and

3. Installed by an installer who is certified by a manufacturer to install that specific product, if such certification is required by the product manufacturer.
Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

Revise as follows:

R303.1 (IRC N1101.10) Identification. Materials, systems, and equipment shall be identified in a manner that will allow a determination of compliance with the applicable provisions of this code. Materials used shall be:

1. Listed for the intended use,
2. Installed in accordance with the manufacturer’s installation instructions, and
3. Installed by an installer who is certified by a manufacturer to install that specific product, if such certification is required by the product manufacturer

Reason: This Section of the code is amended to modify section R303.1 by adding language to make sure that sufficient information exists to ensure that materials and equipment used are designed for that intended use, installed according to the manufacturer’s installation instructions, and are installed by an individual certified to install the product as required by the manufacturer, if the certification exists for that particular product. The manufacturer’s installation instructions are required because many product manufacturers have specific instructions about how their products must be installed to ensure their performance. Requiring the use of the instructions will help ensure the product performs as the manufacturer intended. Some products require installers to pass a certification test to ensure that the product is installed according to the manufacturer’s specifications. Use of a certified installer, if such certification exists for a certain product, will help ensure the product performs as the manufacturer intended. The permit Applicant can submit this information in a number of ways. On the plans, spec sheets, schedules, (such as window schedules and equipment schedules), or any other way deemed acceptable by the code official, as each applies to a specific portion or component of the Building.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal will save money by requiring qualified and trained individuals to install certain products in accordance with manufacturers specs and certifications if required. Doing the job right the first time is a money saver. Not knowing how to do it and doing it wrong will cost money.
Proponent: Kurt Roeper, representing Steel Door Institute (kurt.roeper@assaabloy.com)

2018 International Energy Conservation Code

Revise as follows:

C303.1.3 Fenestration product rating. $U$-factors of fenestration products shall be determined as follows:

1. For windows, doors and skylights, $U$-factor ratings shall be determined in accordance with NFRC 100.
2. Where required for garage doors and rolling doors, $U$-factor ratings shall be determined in accordance with either NFRC 100 or ANSI/DASMA 105.

$U$-factors shall be determined by an accredited, independent laboratory, and labeled and certified by the manufacturer.

Products lacking such a labeled $U$-factor shall be assigned a default $U$-factor from Table C303.1.3(1) or C303.1.3(2). The solar heat gain coefficient (SHGC) and visible transmittance (VT) of glazed fenestration products (windows, glazed doors and skylights) shall be determined in accordance with NFRC 200 by an accredited, independent laboratory, and labeled and certified by the manufacturer. Products lacking such a labeled SHGC or VT shall be assigned a default SHGC or VT from Table C303.1.3(3).

<table>
<thead>
<tr>
<th>TABLE C303.1.3(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT OPAQUE DOOR $U$-FACTORS</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DOOR TYPE</th>
<th>OPAQUEU-FACTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uninsulated Metal</td>
<td>1.20 0.60</td>
</tr>
<tr>
<td>Insulated Metal (Rolling)</td>
<td>0.90</td>
</tr>
<tr>
<td>Insulated Metal (Other)</td>
<td>0.60 0.42</td>
</tr>
<tr>
<td>Wood</td>
<td>0.50</td>
</tr>
<tr>
<td>Insulated, nonmetal edge, max 45% glazing, any glazing double pane</td>
<td>0.35</td>
</tr>
</tbody>
</table>

Reason: The existing default values are not reflective of product performance data. The proposed default values are worst case values derived from testing 26 specimens manufactured by 11 unique steel door manufacturers. A certified test report from an accredited, independent laboratory is appended to this proposal. Testing was conducted in accordance with:

ASTM C1199-09 Standard Test Method for Measuring the Steady-State Thermal Transmittance of Fenestration Systems Using Hot Box Methods

ASTM E1423 – 06 Standard Practice for Determining Steady State Thermal Transmittance of Fenestration Systems

Section 303.1.3 unchanged – see table C303.1.3(2) for proposed change to default values
Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed change to the default values does not impact the cost of construction, it only provides more accurate - worst case - assigned values.
CE39-19
IECC: SECTION C202(New), C303.1.3, C402.4.2, C402.4.2.2, Chapter 6CE (New)

Proponent: Jennifer Hatfield, representing American Architectural Manufacturers Association
(jen@jhatfieldandassociates.com)

2018 International Energy Conservation Code
Revise as follows:

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

VISIBLE TRANSMITTANCE, ANNUAL \([VT_{\text{annual}}]\) The ratio of visible light entering the space through the fenestration product assembly to the incident visible light during the course of a year, which includes the effects of glazing material, frame, and light well or tubular conduit, and is expressed as a number between 0 and 1.

Revise as follows:

C303.1.3 Fenestration product rating. \(U\)-factors of fenestration products shall be determined as follows:

1. For windows, doors and skylights, \(U\)-factor ratings shall be determined in accordance with NFRC 100.
2. Where required for garage doors and rolling doors, \(U\)-factor ratings shall be determined in accordance with either NFRC 100 or ANSI/DASMA 105.

\(U\)-factors shall be determined by an accredited, independent laboratory, and labeled and certified by the manufacturer.

Products lacking such a labeled \(U\)-factor shall be assigned a default \(U\)-factor from Table C303.1.3(1) or C303.1.3(2). The solar heat gain coefficient (SHGC) and visible transmittance (VT) of glazed fenestration products (windows, glazed doors and skylights) shall be determined in accordance with NFRC 200 by an accredited, independent laboratory, and labeled and certified by the manufacturer. Products lacking such a labeled SHGC or VT shall be assigned a default SHGC or VT from Table C303.1.3(3). For Tubular Daylighting Devices, VT\(_{\text{annual}}\) shall be measured and rated in accordance with NFRC 203.

C402.4.2 Minimum skylight fenestration area. In an enclosed space greater than 2,500 square feet (232 m\(^2\)) in floor area, directly under a roof with not less than 75 percent of the ceiling area with a ceiling height greater than 15 feet (4572 mm), and used as an office, lobby, atrium, concourse, corridor, storage space, gymnasium/exercise center, convention center, automotive service area, space where manufacturing occurs, nonrefrigerated warehouse, retail store, distribution/sorting area, transportation depot or workshop, the total toplit daylight zone shall be not less than half the floor area and shall provide one of the following:

1. A minimum skylight area to toplit daylight zone of not less than 3 percent where all skylights have a VT of not less than 0.40, or VT\(_{\text{annual}}\) of not less than 0.26, as determined in accordance with Section C303.1.3.
2. A minimum skylight effective aperture of not less than 1 percent, determined in accordance with Equation 4-4.
Skylight Effective Aperture =
\[
\frac{0.85 \times \text{Skylight Area} \times \text{Skylight VT} \times \text{WF}}{\text{Toplit Zone}}
\]

of:

1. Not less than 1 percent, using a skylight’s VT rating; or
2. Not less than 0.66 percent using a Tubular Daylighting Device’s VT\text{annual} rating.

(Equation 4-4)

where:

Skylight area = Total fenestration area of skylights.

Skylight VT = Area weighted average visible transmittance of skylights.

WF = Area weighted average well factor, where well factor is 0.9 if light well depth is less than 2 feet (610 mm), or 0.7 if light well depth is 2 feet (610 mm) or greater, or 1.0 for Tubular Daylighting Devices with VT\text{annual} ratings.

Light well depth = Measure vertically from the underside of the lowest point of the skylight glazing to the ceiling plane under the skylight.

Exception: Skylights above daylight zones of enclosed spaces are not required in:

2. Spaces where the designed general lighting power densities are less than 0.5 W/ft\text{2} (5.4 W/m\text{2}).
3. Areas where it is documented that existing structures or natural objects block direct beam sunlight on not less than half of the roof over the enclosed area for more than 1,500 daytime hours per year between 8 a.m. and 4 p.m.
4. Spaces where the daylight zone under rooftop monitors is greater than 50 percent of the enclosed space floor area.
5. Spaces where the total area minus the area of sidelight daylight zones is less than 2,500 square feet (232 m\text{2}), and where the lighting is controlled in accordance with Section C405.2.3.

C402.4.2.2 Haze factor. Skylights in office, storage, automotive service, manufacturing, nonrefrigerated warehouse, retail store and distribution/sorting area spaces shall have a glazing material or diffuser with a haze factor greater than 90 percent when tested in accordance with ASTM D1003.

Exception: Skylights and tubular daylighting devices designed and installed to exclude direct sunlight entering the occupied space by the use of fixed or automated baffles or the geometry of skylight and light well, or the use of optical diffuser components.

Add new standard(s) as follows:

NFRC

National Fenestration Rating Council, Inc.
6305 Ivy Lane, Suite 140
Greenbelt MD 20770

203--2017: Procedure for Determining Translucent Fenestration Product Visible Transmittance at Normal Incidence
Reason: The IECC code changes contained in the “IECC C402 Updates to Incorporate NFRC203 VTannual Equivalencies for Tubular Daylighting Devices (TDDs)” document provides recommended additions and edits that will allow the 2021 code language to remain consistent with new fenestration rating standards. The proposed changes incorporate industry-vetted code and Visible Transmittance (VT) rating protocol language that applies necessary equivalency factors for the National Fenestration Rating Council’s new NFRC 203 VTannual Rating Protocol for Tubular Daylighting Devices (TDDs) as an alternative code-compliance option to the NFRC 200/202 VT (VTnormal) rating that is currently used for determining Minimum Skylight Fenestration Area requirements for conventional skylight products.

The traditional NFRC 200/202 Visible Transmittance rating procedure, rates the Visible Transmittance of conventional skylights using a single, direct-normal incidence angle condition, and represents a skylight’s VT for light that is “normal” (i.e. perpendicular) to the skylight’s surface. As a result, it does not account for the skylight’s effective system transmittance under the wide range of lower, incident sunlight angles that actually strike the skylight’s dome surface over the course of a year. To address this, the new NFRC 203 protocol applies enhanced physical Visible Transmittance testing of a TDD/skylight product using 18 precisely-controlled incidence angles, and measures/rates a TDD/skylight product’s functional, annualized visible light transmittance characteristics accounting for the product’s roof-top dome optics, light shaft (or “well” as defined in Code Section C402.4.2), and interior ceiling diffuser and/or aperture elements. It is also important to note that NFRC 203 is the only rating standard that is used for measuring and rating the Visible Transmittance of the TDD fenestration product category.

The code language additions contained in this code proposal, provide the necessary definitions and applicable VT conversion factors that relate a conventional skylight’s NFRC 202 direct-normal (VTnormal) rating to the functional VTannual performance as determined using the NFRC 203 rating protocol, and enable the new NFRC 203 ratings to be used when determining a TDD’s Skylight Effective Aperture value using Equation 4-4 in code section C402.4.2. Also, since the NFRC 203 Rating Protocol tests the TDD/Skylight in its entirety, including a default 3-foot long tube run (or “well”), all resulting NFRC 203 VTannual Ratings include the TDD’s well factor in the Product’s Visible Transmittance Data and Rating. As such, no further Well Factor (WF) adjustment is warranted, and a well factor of 1.0 should be applied in Equation 4-4.

The intent of applying the TDDs to the exception in code section C402.4.2.2, when optical diffuser components are present, is based on the defined scope of ASTM D1003.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposed code edits/additions represent a cost-neutral change to the IECC. They merely provide the necessary definitions and conversion factors that allow the new, more rigorous NFRC 203 product ratings to be applied to Code Section C402.4.2 with equivalency to the existing conventional NFRC 200/202 skylight ratings, and are expected to increase the overall usability of the standard. The proposed code changes do not change the stringency of the standard, and as such, they do not impact the resulting energy savings or the associated cost of compliance.

Staff Analysis: A review of the standard proposed for inclusion in the code, NFRC 203-2017, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Analysis: A review of the standard proposed for inclusion in the code, NFRC 203, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

PART I — IECC: Part I: C303.1.2
IECC: Part II: R303.1.2.

PART II — IECC: R303.1.2 (IRC N1101.10.2)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C303
MATERIALS, SYSTEMS AND EQUIPMENT

C303.1.2 Insulation mark installation. Insulating materials shall be installed such that the manufacturer’s $R$-value mark is readily observable upon inspection. For insulation materials that are installed without an observable manufacturer’s $R$-value mark, such as blown or draped products, an insulation certificate complying with Section C303.1.1 shall be left immediately after installation by the installer, in a conspicuous location within the building, to certify the installed $R$-value of the insulation material.

Proposal # 4802
CE40-19 Part II

IECC: R303.1.2 (IRC N1101.10.2)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

R303.1.2 (IRC N1101.10.2) Insulation mark installation. Insulating materials shall be installed such that the manufacturer’s $R$-value mark is readily observable at inspection. For insulation materials that are installed without an observable manufacturer’s $R$-value mark, such as blown or draped products, an insulation certificate complying with Section R303.1.1 shall be left immediately after installation by the installer, in a conspicuous location within the building, to certify the installed $R$-value of the insulation material.

Reason: More and more insulation products are being developed and installed that do not come with a manufacturer’s $R$-value marking. Primarily these are blown insulation materials that are dependent on the density of the blown product installation to ensure proper $R$-value of the material. Many materials can be blown at different densities to achieve different $R$-values and there is no visible way to verify if the required or specified $R$-value has been achieved. In lieu of mandating density quality assurance checks on the installation of blown insulation material, a requirement that the installer of the material certify the $R$-value of the installation will allow the Code Official, Energy Rater, third party inspection agency, HVAC contractor, and others who must use the $R$-value for calculations or verification of the code, to be satisfied that what is installed actually meets the $R$-value requirements.

Being able to rely on a document that certifies the $R$-value of the installed material that is not labeled will take pressure of the code official to document that the $R$-value installed matches the submitted and approved documentation for obtaining the building permit. Required Manual J and S HVAC design reports are an example of document that fundamentally rely on the proper installation of the $R$-values that have been specified for the dwelling. If the $R$-value is less or more than that used in the HVAC design the mechanical heating and cooling equipment could be over or undersized impacting the energy performance of the home. Lastly, a certified document helps code officials have confidence that others that are using the $R$-value of the home to demonstrate compliance are accurately representing $R$-values that are installed in the home.

Other insulation materials that often are installed without observable $R$-value Marks include vinyl draped fiberglass blankets or fiberglass batt material that is marked with a color that blends into the color of the fiberglass. In addition, most batt material is marked in one location and or one side of the material so when it is cut to fit in a rim joist, for example, it is not visible to the inspector.

In order to right size HVAC systems, create an accurate computer model for the EIR or simulated performance path, and/or properly verify code required $R$-values, “observable” should be enforced consistently and inspectors should not have to search for or question what they are looking at. A certificate that certifies the installed materials $R$-value per component left at the time of the install rather than just at final will solve this issue.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Cost of construction should not increase as documentation of the installation is already required. This proposal clarifies that the document must be left at the time of the installation (rough stage of construction) as well as when attic blow or other secondary trips are made or needed.

IECC: C401.2, C401.2.1 (New), C401.2.2 (New), C402.1, C407.2, C407.3

Proponent: David Collins, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with C401.2.1 or C401.2.2, one of the following:
1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C406 and C408. In addition, commercial buildings shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

Add new text as follows:

C401.2.1 International Energy Conservation Code. Commercial buildings shall comply with one of the following:
1. Prescriptive Compliance. The Prescriptive Compliance Option requires compliance with Sections C402 through C406 and C408
2. Total Building Performance. The Total Building Performance Option requires compliance with Section C407.

Exception: Additions, alterations, repairs and changes of occupancy to existing buildings complying with Chapter 5.

C401.2.2 ASHRAE 90.1. Commercial buildings shall comply with the requirements of ANSI/ASHRAE/IESNA 90.1.

Revise as follows:

C402.1 General (Prescriptive). Building thermal envelope assemblies for buildings that are intended to comply with the code on a prescriptive basis in accordance with the compliance path described in Item 2 of 1of Section C401.2.1, shall comply with the following:
1. The opaque portions of the building thermal envelope shall comply with the specific insulation requirements of Section C402.2 and the thermal requirements of either the $R$-value-based method of Section C402.1.3; the $U$, $C$, and $F$-factor-based method of Section C402.1.4; or the component performance alternative of Section C402.1.5.
2. Roof solar reflectance and thermal emittance shall comply with Section C402.3.
3. Fenestration in building envelope assemblies shall comply with Section C402.4.
4. Air leakage of building envelope assemblies shall comply with Section C402.5.

Alternatively, where buildings have a vertical fenestration area or skylight area exceeding that allowed in Section C402.4, the building and building thermal envelope shall comply with Section C401.2, Item 1 or Section C401.2, Item 3.
Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with Section C403.10.1 or C403.10.2.

**C407.2 Mandatory requirements.** Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.1, C405.2, C405.4 through C405.9, and C408.

**C407.3 Performance-based compliance.** Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to 85% of the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration's State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be no more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

**Exception:** Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

**Reason:** No technical changes are intended. No advantage to any proprietary interests governed by the code is intended. The intent is to strictly make the IECC more understandable and easier to use, as explained below.
Currently mandatory provisions are referenced in Section C401.2 (3) and listed again in a conflicting list within Section C407. Eliminating the C401.2 (3) list leaves mandatory elements singularly listed within C407 which resolves conflicts.

Naming the compliance options (prescriptive, performance) formalizes the way in which the paths are typically identified. Using the word “option” reinforces that it is the designer’s choice as to which path is followed.

This change also further clarifies that one cannot combine the IECC and ASHRAE compliance paths on a given project.

In creating the singular list of mandatory requirements in C407, it also clarifies that C405.3 Lighting Power Densities is Prescriptive, and labeled as such, while C405.1, C405.2, C405.4, C405.6 and C405.7 are labeled mandatory. C408 which was listed in C401.2 is now included in C407.

This proposal also relocates the 85 percent requirement from Section C401.2 (3) to Section C407. Making this change puts all of the performance path targets in C407, either directly or by reference.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This change does not increase or decrease code provisions nor impact construction methods. It clarifies language and provisions already contained in the code.

Proposal # 4180

CE41-19
CE42-19 Part I

PART I — IECC: C401.2, SECTION C407, C407.1, C407.2, C407.3, Table C407.2 (New), C102.1.1, C402.1, C402.2, C402.4, C402.5, C403.2, C403.2.1, C403.2.2, C403.3, C403.3.1, C403.3.2, C403.3.2.1, C403.4, C403.4.1, C403.4.1.1, C403.4.1.2, C403.4.1.3, C403.4.1.4, C403.4.1.5, C403.4.2, C403.4.2.1, C403.4.2.2, C403.4.2.3, C403.4.3, C403.5, C403.5.5, C403.7.1, C403.7.2, C403.7.3, C403.7.4, C403.7.5, C403.7.6, C403.7.7, C403.8.1, C403.8.2, C403.8.3, C403.8.4, C403.10.1, C403.10.2, C403.10.2.1, C403.10.3, C403.11.1, C403.11.2, C403.11.2.1, C403.11.2.2, C403.11.2.3, C403.11.3, C403.11.3.1, C403.12, SECTION C404, C404.9, C404.10, C405.1, C405.2, C405.3, C405.4, C405.4.3, C405.5, C405.6, C405.7

PART II — IECC: R102.1.1 (IRC N1101.4), R401.3 (IRC N1101.14), R402.1 (IRC N1102.1), R402.2 (IRC N1102.2), R402.3 (IRC N1102.3), R402.4 (IRC N1102.4), R402.5 (IRC N1102.5), R403.1 (IRC N1103.1), R403.1.2 (IRC N1103.1.2), R403.3.1 (IRC N1103.3.1), R403.3.2 (IRC N1103.3.2), R403.3.3 (IRC N1103.3.3), R403.3.4 (IRC N1103.3.4), R403.3.5 (IRC N1103.3.5), R403.4 (IRC N1103.4), R403.5.1 (IRC N1103.5.1), R403.5.3 (IRC N1103.5.3), R403.6 (IRC N1103.6), R403.7 (IRC N1103.7), R403.8 (IRC N1103.8), R403.9 (IRC N1103.9), R403.10 (IRC N1103.10), R403.11 (IRC N1103.11), R404.1.1 (IRC N1104.1), R404.1.1 (IRC N1104.1.1), R405.1 (IRC N1105.3), R406 (IRC N1106.2), C403.2, C403.3, C403.4 through C403.4.2.3, C403.5, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

Section C407

SECTION C407
TOTAL BUILDING PERFORMANCE

C407.1 Scope. This section establishes criteria for compliance using total building performance. The following systems and loads shall be included in determining the total building performance: heating systems, cooling systems, service water heating, fan systems, lighting power, receptacle loads and process loads.

Exception: Energy used to recharge or refuel vehicles that are used for on-road and off-site transportation purposes.

Delete without substitution:
C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.

Revise as follows:

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have a design meet all of the following:

1. The requirements of the sections indicated within Table C407.2
2. An annual energy cost that is less than or equal to 85 percent the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

Exception: Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

Revise as follows:

C102.1.1 Above code programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy efficiency program shall be considered to be in compliance with this code. The requirements identified as “mandatory” in Chapter 4 Table C407.2 shall be met.

C402.1 General (Prescriptive). Building thermal envelope assemblies for buildings that are intended to comply with the code on a prescriptive basis in accordance with the compliance path described in Item 2 of Section C401.2, shall comply with the following:

1. The opaque portions of the building thermal envelope shall comply with the specific insulation requirements of Section C402.2 and the thermal requirements of either the R-value-based method of Section C402.1.3; the U-, C- and F-factor-based method of Section C402.1.4; or the component performance alternative of Section C402.1.5.
2. Roof solar reflectance and thermal emittance shall comply with Section C402.3.
3. Fenestration in building envelope assemblies shall comply with Section C402.4.
4. Air leakage of building envelope assemblies shall comply with Section C402.5.

Alternatively, where buildings have a vertical fenestration area or skylight area exceeding that allowed in Section C402.4, the building and building thermal envelope shall comply with Section C401.2, Item 1 or Section C401.2, Item 3.

Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with Section C403.10.1 or C403.10.2.

C402.2 Specific building thermal envelope insulation requirements (Prescriptive). Insulation in building thermal envelope opaque assemblies shall comply with Sections C402.2.1 through C402.2.7 and Table C402.1.3.

C402.4 Fenestration (Prescriptive). Fenestration shall comply with Sections C402.4.1 through C402.4.5 and Table C402.4. Daylight responsive controls shall comply with this section and Section C405.2.3.1.

C402.5 Air leakage—thermal envelope (Mandatory). The thermal envelope of buildings shall comply with Sections C402.5.1 through C402.5.8, or the building thermal envelope shall be tested in accordance with ASTM E 779 at a pressure differential of 0.3 inch water gauge (75 Pa) or an equivalent method approved by the code official and deemed to comply with the provisions of this section when the tested air leakage rate of the building thermal envelope is not greater than 0.40 cfm/ft² (2.0 L/s • m²). Where compliance is based on such testing, the building shall also comply with Sections C402.5.5, C402.5.6 and C402.5.7.

C403.2 System design (Mandatory). Mechanical systems shall be designed to comply with Sections C403.2.1 and C403.2.2. Where elements of a building’s mechanical systems are addressed in Sections C403.3 through C403.12, such elements shall comply with the applicable provisions of those sections.

C403.2.1 Zone isolation required (Mandatory). HVAC systems serving zones that are over 25,000 square feet (2323 m²) in floor area or that span more than one floor and are designed to operate or be occupied nonsimultaneously shall be divided into isolation areas. Each isolation area shall be equipped with isolation devices and controls configured to automatically shut off the supply of conditioned air and outdoor air to and exhaust air from the isolation area. Each isolation area shall be controlled independently by a device meeting the requirements of Section C403.4.2.2. Central systems and plants shall be provided with controls and devices that will allow system and equipment operation for any length of time while serving only the smallest isolation
area served by the system or plant.

Exceptions:

1. Exhaust air and outdoor air connections to isolation areas where the fan system to which they connect is not greater than 5,000 cfm (2360 L/s).
2. Exhaust airflow from a single isolation area of less than 10 percent of the design airflow of the exhaust system to which it connects.
3. Isolation areas intended to operate continuously or intended to be inoperative only when all other isolation areas in a zone are inoperative.

C403.2.2 Ventilation (Mandatory). Ventilation, either natural or mechanical, shall be provided in accordance with Chapter 4 of the International Mechanical Code. Where mechanical ventilation is provided, the system shall provide the capability to reduce the outdoor air supply to the minimum required by Chapter 4 of the International Mechanical Code.

C403.3 Heating and cooling equipment efficiencies (Mandatory). Heating and cooling equipment installed in mechanical systems shall be sized in accordance with Section C403.3.1 and shall be not less efficient in the use of energy than as specified in Section C403.3.2.

C403.3.1 Equipment sizing (Mandatory). The output capacity of heating and cooling equipment shall be not greater than that of the smallest available equipment size that exceeds the loads calculated in accordance with Section C403.1.1. A single piece of equipment providing both heating and cooling shall satisfy this provision for one function with the capacity for the other function as small as possible, within available equipment options.

Exceptions:

1. Required standby equipment and systems provided with controls and devices that allow such systems or equipment to operate automatically only when the primary equipment is not operating.
2. Multiple units of the same equipment type with combined capacities exceeding the design load and provided with controls that are configured to sequence the operation of each unit based on load.

C403.3.2 HVAC equipment performance requirements (Mandatory). Equipment shall meet the minimum efficiency requirements of Tables C403.3.2(1) through C403.3.2(9) when tested and rated in accordance with the applicable test procedure. Plate-type liquid-to-liquid heat exchangers shall meet the minimum requirements of Table C403.3.2(10). The efficiency shall be verified through certification under an approved certification program or, where a certification program does not exist, the equipment efficiency ratings shall be supported by data furnished by the manufacturer. Where multiple rating conditions or performance requirements are provided, the equipment shall satisfy all stated requirements. Where components, such as indoor or outdoor coils, from different manufacturers are used, calculations and supporting data shall be furnished by the designer that demonstrates that the combined efficiency of the specified components meets the requirements herein.

C403.3.2.1 Water-cooled centrifugal chilling packages (Mandatory). Equipment not designed for operation at AHRI Standard 550/590 test conditions of 44°F (7°C) leaving chilled-water temperature and 2.4 gpm/ton evaporator fluid flow and 85°F (29°C) entering condenser water temperature with 3 gpm/ton (0.054 l/s • kW) condenser water flow shall have maximum full-load kW/ton (FL) and part-load ratings requirements adjusted using Equations 4-6 and 4-7.

\[
FL_{adj} = FL/K_{adj} \\
FL_{adj} = FL/K_{adj}
\]
(Equation 4-6)

\[ PLV_{\text{adj}} = IPLV / K_{\text{adj}} \]

\[ PLV_{\text{adj}} = IPLV / K_{\text{adj}} \]

(Equation 4-7)

where:

\[ K_{\text{adj}} = A \times B \]

\[ FL = \text{Full-load kW/ton value as specified in Table C403.3.2(7).} \]

\[ FL_{\text{adj}} = \text{Maximum full-load kW/ton rating, adjusted for nonstandard conditions.} \]

\[ IPLV = \text{Value as specified in Table C403.3.2(7).} \]

\[ PLV_{\text{adj}} = \text{Maximum } NPLV \text{ rating, adjusted for nonstandard conditions.} \]

\[ A = 0.00000014592 \times (LIFT)^4 0.0000346496 \times (LIFT)^3 + 0.00314196 \times (LIFT)^2 - 0.147199 \times (LIFT) + 3.9302 \]

\[ B = 0.0015 \times LG_E + 0.934 \]

\[ LIFT = LG_{\text{Cond}} - LG_{\text{Evap}} \]

\[ LG_{\text{Cond}} = \text{Full-load condenser leaving fluid temperature (°F).} \]

\[ LG_{\text{Evap}} = \text{Full-load evaporator leaving temperature (°F).} \]

The \( FL_{\text{adj}} \) and \( PLV_{\text{adj}} \) values are only applicable for centrifugal chillers meeting all of the following full-load design ranges:

1. Minimum evaporator leaving temperature: 36°F.
2. Maximum condenser leaving temperature: 115°F.
3. 20°F ≤ LIFT ≤ 80°F.

C403.4 Heating and cooling system controls (Mandatory). Each heating and cooling system shall be provided with controls in accordance with Sections C403.4.1 through C403.4.5.

C403.4.1 Thermostatic controls (Mandatory). The supply of heating and cooling energy to each zone shall be controlled by individual thermostatic controls capable of responding to temperature within the zone. Where humidification or dehumidification or both is provided, not fewer than one humidity control device shall be provided for each humidity control system.

**Exception:** Independent perimeter systems that are designed to offset only building envelope heat losses, gains or both serving one or more perimeter zones also served by an interior system provided that both of the following conditions are met:

1. The perimeter system includes not fewer than one thermostatic control zone for each building exposure having exterior walls facing only one orientation (within ± 45 degrees) (0.8 rad) for more than 50 contiguous feet (15 240 mm).
2. The perimeter system heating and cooling supply is controlled by thermostats located within the zones served by the system.
C403.4.1.1 Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric resistance heat shall have controls that, except during defrost, prevent supplementary heat operation where the heat pump can provide the heating load.

C403.4.1.2 Deadband (Mandatory). Where used to control both heating and cooling, zone thermostatic controls shall be configured to provide a temperature range or deadband of not less than 5°F (2.8°C) within which the supply of heating and cooling energy to the zone is shut off or reduced to a minimum.

Exceptions:

1. Thermostats requiring manual changeover between heating and cooling modes.
2. Occupancies or applications requiring precision in indoor temperature control as approved by the code official.

C403.4.1.3 Setpoint overlap restriction (Mandatory). Where a zone has a separate heating and a separate cooling thermostatic control located within the zone, a limit switch, mechanical stop or direct digital control system with software programming shall be configured to prevent the heating setpoint from exceeding the cooling setpoint and to maintain a deadband in accordance with Section C403.4.1.2.

C403.4.1.4 Heated or cooled vestibules (Mandatory). The heating system for heated vestibules and air curtains with integral heating shall be provided with controls configured to shut off the source of heating when the outdoor air temperature is greater than 45°F (7°C). Vestibule heating and cooling systems shall be controlled by a thermostat located in the vestibule configured to limit heating to a temperature not greater than 60°F (16°C) and cooling to a temperature not less than 85°F (29°C).

Exception: Control of heating or cooling provided by site-recovered energy or transfer air that would otherwise be exhausted.

C403.4.1.5 Hot water boiler outdoor temperature setback control (Mandatory). Hot water boilers that supply heat to the building through one- or two-pipe heating systems shall have an outdoor setback control that lowers the boiler water temperature based on the outdoor temperature.

C403.4.2 Off-hour controls (Mandatory). Each zone shall be provided with thermostatic setback controls that are controlled by either an automatic time clock or programmable control system.

Exceptions:

1. Zones that will be operated continuously.
2. Zones with a full HVAC load demand not exceeding 6,800 Btu/h (2 kW) and having a manual shutoff switch located with ready access.

C403.4.2.1 Thermostatic setback (Mandatory). Thermostatic setback controls shall be configured to set back or temporarily operate the system to maintain zone temperatures down to 55°F (13°C) or up to 85°F (29°C).

C403.4.2.2 Automatic setback and shutdown (Mandatory). Automatic time clock or programmable controls shall be capable of starting and stopping the system for seven different daily schedules per week and retaining their programming and time setting during a loss of power for not fewer than 10 hours. Additionally, the controls shall have a manual override that allows temporary operation of the system for up to 2 hours; a manually operated timer configured to operate the system for up to 2 hours; or an occupancy sensor.

C403.4.2.3 Automatic start (Mandatory). Automatic start controls shall be provided for each HVAC system. The controls shall be configured to automatically adjust the daily start time of the HVAC system in order to bring each space to the desired occupied temperature immediately prior to scheduled occupancy.
C403.4.3 Hydronic systems controls. The heating of fluids that have been previously mechanically cooled and the cooling of fluids that have been previously mechanically heated shall be limited in accordance with Sections C403.4.3.1 through C403.4.3.3. Hydronic heating systems comprised of multiple-packaged boilers and designed to deliver conditioned water or steam into a common distribution system shall include automatic controls configured to sequence operation of the boilers. Hydronic heating systems composed of a single boiler and greater than 500,000 Btu/h (146.5 kW) input design capacity shall include either a multistaged or modulating burner.

C403.5 Economizers (Prescriptive). Economizers shall comply with Sections C403.5.1 through C403.5.5. An air or water economizer shall be provided for the following cooling systems:

1. Chilled water systems with a total cooling capacity, less cooling capacity provided with air economizers, as specified in Table C403.5(1).
2. Individual fan systems with cooling capacity greater than or equal to 54,000 Btu/h (15.8 kW) in buildings having other than a Group R occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 300,000 Btu/h (88 kW), whichever is greater.
3. Individual fan systems with cooling capacity greater than or equal to 270,000 Btu/h (79.1 kW) in buildings having a Group R occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 1,500,000 Btu/h (440 kW), whichever is greater.

Exceptions: Economizers are not required for the following systems.

1. Individual fan systems not served by chilled water for buildings located in Climate Zones 1A and 1B.
2. Where more than 25 percent of the air designed to be supplied by the system is to spaces that are designed to be humidified above 35°F (1.7°C) dew-point temperature to satisfy process needs.
3. Systems expected to operate less than 20 hours per week.
4. Systems serving supermarket areas with open refrigerated casework.
5. Where the cooling efficiency is greater than or equal to the efficiency requirements in Table C403.5(2).
6. Systems that include a heat recovery system in accordance with Section C403.9.5.

C403.5.5 Economizer fault detection and diagnostics (Mandatory). Air-cooled unitary direct-expansion units listed in Tables C403.3.2(1) through C403.3.2(3) and variable refrigerant flow (VRF) units that are equipped with an economizer in accordance with Sections C403.5 through C403.5.4 shall include a fault detection and diagnostics system complying with the following:

1. The following temperature sensors shall be permanently installed to monitor system operation:
   1.1. Outside air.
   1.2. Supply air.
   1.3. Return air.
2. Temperature sensors shall have an accuracy of ±2°F (1.1°C) over the range of 40°F to 80°F (4°C to 26.7°C).
3. Refrigerant pressure sensors, where used, shall have an accuracy of ±3 percent of full scale.
4. The unit controller shall be configured to provide system status by indicating the following:
   4.1. Free cooling available.
   4.2. Economizer enabled.
   4.3. Compressor enabled.
4.4. Heating enabled.
4.5. Mixed air low limit cycle active.
4.6. The current value of each sensor.

5. The unit controller shall be capable of manually initiating each operating mode so that the operation of compressors, economizers, fans and the heating system can be independently tested and verified.

6. The unit shall be configured to report faults to a fault management application available for access by day-to-day operating or service personnel, or annunciated locally on zone thermostats.

7. The fault detection and diagnostics system shall be configured to detect the following faults:
   7.1. Air temperature sensor failure/fault.
   7.2. Not economizing when the unit should be economizing.
   7.3. Economizing when the unit should not be economizing.
   7.4. Damper not modulating.
   7.5. Excess outdoor air.

C403.7.1 Demand control ventilation (Mandatory). Demand control ventilation (DCV) shall be provided for spaces larger than 500 square feet (46.5 m²) and with an average occupant load of 25 people or greater per 1,000 square feet (93 m²) of floor area, as established in Table 403.3.1.1 of the International Mechanical Code, and served by systems with one or more of the following:

1. An air-side economizer.
2. Automatic modulating control of the outdoor air damper.
3. A design outdoor airflow greater than 3,000 cfm (1416 L/s).

Exceptions:

1. Systems with energy recovery complying with Section C403.7.4.
2. Multiple-zone systems without direct digital control of individual zones communicating with a central control panel.
3. Systems with a design outdoor airflow less than 1,200 cfm (566 L/s).
4. Spaces where the supply airflow rate minus any makeup or outgoing transfer air requirement is less than 1,200 cfm (566 L/s).
5. Ventilation provided only for process loads.

C403.7.2 Enclosed parking garage ventilation controls (Mandatory). Enclosed parking garages used for storing or handling automobiles operating under their own power shall employ contamination-sensing devices and automatic controls configured to stage fans or modulate fan average airflow rates to 50 percent or less of design capacity, or intermittently operate fans less than 20 percent of the occupied time or as required to maintain acceptable contaminant levels in accordance with International Mechanical Code provisions. Failure of contamination-sensing devices shall cause the exhaust fans to operate continuously at design airflow.

Exceptions:

1. Garages with a total exhaust capacity less than 22,500 cfm (10 620 L/s) with ventilation systems that do not utilize heating or mechanical cooling.
2. Garages that have a garage area to ventilation system motor nameplate power ratio that exceeds 1125 cfm/hp (710 L/s/kW) and do not utilize heating or mechanical cooling.

C403.7.3 Ventilation air heating control (Mandatory). Units that provide ventilation air to multiple zones and operate in conjunction with zone heating and cooling systems shall not use heating or heat recovery to warm
supply air to a temperature greater than 60°F (16°C) when representative building loads or outdoor air temperatures indicate that the majority of zones require cooling.

C403.7.4 Energy recovery ventilation systems (Mandatory). Where the supply airflow rate of a fan system exceeds the values specified in Tables C403.7.4(1) and C403.7.4(2), the system shall include an energy recovery system. The energy recovery system shall be configured to provide a change in the enthalpy of the outdoor air supply of not less than 50 percent of the difference between the outdoor air and return air enthalpies, at design conditions. Where an air economizer is required, the energy recovery system shall include a bypass or controls that permit operation of the economizer as required by Section C403.5.

Exception: An energy recovery ventilation system shall not be required in any of the following conditions:

1. Where energy recovery systems are prohibited by the International Mechanical Code.
2. Laboratory fume hood systems that include not fewer than one of the following features:
   2.1. Variable-air-volume hood exhaust and room supply systems configured to reduce exhaust and makeup air volume to 50 percent or less of design values.
   2.2. Direct makeup (auxiliary) air supply equal to or greater than 75 percent of the exhaust rate, heated not warmer than 2°F (1.1°C) above room setpoint, cooled to not cooler than 3°F (1.7°C) below room setpoint, with no humidification added, and no simultaneous heating and cooling used for dehumidification control.
3. Systems serving spaces that are heated to less than 60°F (15.5°C) and that are not cooled.
4. Where more than 60 percent of the outdoor heating energy is provided from site-recovered or site-solar energy.
5. Heating energy recovery in Climate Zones 1 and 2.
6. Cooling energy recovery in Climate Zones 3C, 4C, 5B, 5C, 6B, 7 and 8.
7. Systems requiring dehumidification that employ energy recovery in series with the cooling coil.
8. Where the largest source of air exhausted at a single location at the building exterior is less than 75 percent of the design outdoor air flow rate.
9. Systems expected to operate less than 20 hours per week at the outdoor air percentage covered by Table C403.7.4(1).
10. Systems exhausting toxic, flammable, paint or corrosive fumes or dust.
11. Commercial kitchen hoods used for collecting and removing grease vapors and smoke.

C403.7.5 Kitchen exhaust systems (Mandatory). Replacement air introduced directly into the exhaust hood cavity shall not be greater than 10 percent of the hood exhaust airflow rate. Conditioned supply air delivered to any space shall not exceed the greater of the following:

1. The ventilation rate required to meet the space heating or cooling load.
2. The hood exhaust flow minus the available transfer air from adjacent space where available transfer air is considered to be that portion of outdoor ventilation air not required to satisfy other exhaust needs, such as restrooms, and not required to maintain pressurization of adjacent spaces.

Where total kitchen hood exhaust airflow rate is greater than 5,000 cfm (2360 L/s), each hood shall be a factory-built commercial exhaust hood listed by a nationally recognized testing laboratory in compliance with UL 710. Each hood shall have a maximum exhaust rate as specified in Table C403.7.5 and shall comply with one of the following:

1. Not less than 50 percent of all replacement air shall be transfer air that would otherwise be exhausted.
2. Demand ventilation systems on not less than 75 percent of the exhaust air that are configured to provide not less than a 50-percent reduction in exhaust and replacement air system airflow rates, including controls necessary to modulate airflow in response to appliance operation and to maintain full capture and containment of smoke, effluent and combustion products during cooking and idle.

3. Listed energy recovery devices with a sensible heat recovery effectiveness of not less than 40 percent on not less than 50 percent of the total exhaust airflow.

Where a single hood, or hood section, is installed over appliances with different duty ratings, the maximum allowable flow rate for the hood or hood section shall be based on the requirements for the highest appliance duty rating under the hood or hood section.

**Exception:** Where not less than 75 percent of all the replacement air is transfer air that would otherwise be exhausted.

**C403.7.6 Automatic control of HVAC systems serving guestrooms (Mandatory).** In Group R-1 buildings containing more than 50 guestrooms, each guestroom shall be provided with controls complying with the provisions of Sections C403.7.6.1 and C403.7.6.2. Card key controls comply with these requirements.

**C403.7.7 Shutoff dampers (Mandatory).** Outdoor air intake and exhaust openings and stairway and shaft vents shall be provided with Class I motorized dampers. The dampers shall have an air leakage rate not greater than 4 cfm/ft² (20.3 L/s • m²) of damper surface area at 1.0 inch water gauge (249 Pa) and shall be labeled by an approved agency when tested in accordance with AMCA 500D for such purpose. Outdoor air intake and exhaust dampers shall be installed with automatic controls configured to close when the systems or spaces served are not in use or during unoccupied period warm-up and setback operation, unless the systems served require outdoor or exhaust air in accordance with the International Mechanical Code or the dampers are opened to provide intentional economizer cooling.

Stairway and shaft vent dampers shall be installed with automatic controls configured to open upon the activation of any fire alarm initiating device of the building’s fire alarm system or the interruption of power to the damper.

**Exception:** Nonmotorized gravity dampers shall be an alternative to motorized dampers for exhaust and relief openings as follows:

1. In buildings less than three stories in height above grade plane.
2. In buildings of any height located in Climate Zones 1, 2 or 3.
3. Where the design exhaust capacity is not greater than 300 cfm (142 L/s).

Nonmotorized gravity dampers shall have an air leakage rate not greater than 20 cfm/ft² (101.6 L/s • m²) where not less than 24 inches (610 mm) in either dimension and 40 cfm/ft² (203.2 L/s • m²) where less than 24 inches (610 mm) in either dimension. The rate of air leakage shall be determined at 1.0 inch water gauge (249 Pa) when tested in accordance with AMCA 500D for such purpose. The dampers shall be labeled by an approved agency.

**C403.8.1 Allowable fan horsepower (Mandatory).** Each HVAC system having a total fan system motor nameplate horsepower exceeding 5 hp (3.7 kW) at fan system design conditions shall not exceed the allowable fan system motor nameplate hp (Option 1) or fan system bhp (Option 2) shown in Table C403.8.1(1). This includes supply fans, exhaust fans, return/relief fans, and fan-powered terminal units associated with systems providing heating or cooling capability. Single-zone variable air volume systems shall comply with the constant volume fan power limitation.
Exceptions:

1. Hospital, vivarium and laboratory systems that utilize flow control devices on exhaust or return to maintain space pressure relationships necessary for occupant health and safety or environmental control shall be permitted to use variable volume fan power limitation.
2. Individual exhaust fans with motor nameplate horsepower of 1 hp (0.746 kW) or less are exempt from the allowable fan horsepower requirement.

C403.8.2 Motor nameplate horsepower (Mandatory). For each fan, the fan brake horsepower shall be indicated on the construction documents and the selected motor shall be not larger than the first available motor size greater than the following:

1. For fans less than 6 bhp (4413 W), 1.5 times the fan brake horsepower.
2. For fans 6 bhp (4413 W) and larger, 1.3 times the fan brake horsepower.
3. Systems complying with Section C403.8.1 fan system motor nameplate hp (Option 1).

Exception: Fans with motor nameplate horsepower less than 1 hp (746 W) are exempt from this section.

C403.8.3 Fan efficiency (Mandatory). Fans shall have a fan efficiency grade (FEG) of not less than 67, as determined in accordance with AMCA 205 by an approved, independent testing laboratory and labeled by the manufacturer. The total efficiency of the fan at the design point of operation shall be within 15 percentage points of the maximum total efficiency of the fan.

Exception: The following fans are not required to have a fan efficiency grade:

1. Fans of 5 hp (3.7 kW) or less as follows:
   1.1. Individual fans with a motor nameplate horsepower of 5 hp (3.7 kW) or less, unless Exception 1.2 applies.
   1.2. Multiple fans in series or parallel that have a combined motor nameplate horsepower of 5 hp (3.7 kW) or less and are operated as the functional equivalent of a single fan.
2. Fans that are part of equipment covered in Section C403.3.2.
3. Fans included in an equipment package certified by an approved agency for air or energy performance.
4. Powered wall/roof ventilators.
5. Fans outside the scope of AMCA 205.
6. Fans that are intended to operate only during emergency conditions.

C403.8.4 Fractional hp fan motors (Mandatory). Motors for fans that are not less than $\frac{1}{12}$ hp (0.082 kW) and less than 1 hp (0.746 kW) shall be electronically commutated motors or shall have a minimum motor efficiency of 70 percent, rated in accordance with DOE 10 CFR 431. These motors shall have the means to adjust motor speed for either balancing or remote control. The use of belt-driven fans to sheave adjustments for airflow balancing instead of a varying motor speed shall be permitted.

Exceptions: The following motors are not required to comply with this section

1. Motors in the airstream within fan coils and terminal units that only provide heating to the space served.
2. Motors in space-conditioning equipment that comply with Section C403.3.2 or Sections C403.8.1. through C403.8.3.
3. Motors that comply with Section C405.7.
C403.10.1 Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers (Mandatory). Refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with this section. Walk-in coolers and walk-in freezers that are neither site assembled nor site constructed shall comply with the following:

1. Be equipped with automatic door-closers that firmly close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   **Exception:** Automatic closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall have strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when doors are open.

3. Walk-in coolers and refrigerated warehouse coolers shall contain wall, ceiling, and door insulation of not less than R-25 and walk-in freezers and refrigerated warehouse freezers shall contain wall, ceiling and door insulation of not less than R-32.
   **Exception:** Glazed portions of doors or structural members need not be insulated.

4. Walk-in freezers shall contain floor insulation of not less than R-28.

5. Transparent reach-in doors for walk-in freezers and windows in walk-in freezer doors shall be of triple-pane glass, either filled with inert gas or with heat-reflective treated glass.

6. Windows and transparent reach-in doors for walk-in coolers shall be of double-pane or triple-pane, inert gas-filled, heat-reflective treated glass.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall use electronically commutated motors, brushless direct-current motors, or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) shall use electronically commutated motors, permanent split capacitor-type motors or 3-phase motors.

9. Where antisweat heaters without antisweat heater controls are provided, they shall have a total door rail, glass and frame heater power draw of not more than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers and 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.

10. Where antisweat heater controls are provided, they shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Lights in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall either use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, or shall use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, in conjunction with a device that turns off the lights within 15 minutes when the space is not occupied.

C403.10.2 Walk-in coolers and walk-in freezers (Mandatory). Site-assembled or site-constructed walk-in coolers and walk-in freezers shall comply with the following:

1. Automatic door closers shall be provided that fully close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   **Exception:** Closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall be provided with strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when the doors are open.

3. Walls shall be provided with insulation having a thermal resistance of not less than R-25, ceilings shall be provided with insulation having a thermal resistance of not less than R-25 and doors of walk-in coolers and walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-32.
   **Exception:** Insulation is not required for glazed portions of doors or at structural members.
associated with the walls, ceiling or door frame.

4. The floor of walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-28.

5. Transparent reach-in doors for and windows in opaque walk-in freezer doors shall be provided with triple-pane glass having the interstitial spaces filled with inert gas or provided with heat-reflective treated glass.

6. Transparent reach-in doors for and windows in opaque walk-in cooler doors shall be double-pane heat-reflective treated glass having the interstitial space gas filled.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall be electronically commutated motors or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) in capacity shall be of the electronically commutated or permanent split capacitor-type or shall be 3-phase motors.

   Exception: Fan motors in walk-in coolers and walk-in freezers combined in a single enclosure greater than 3,000 square feet (279 m²) in floor area are exempt.

9. Antisweat heaters that are not provided with anti-sweat heater controls shall have a total door rail, glass and frame heater power draw not greater than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers, and not greater than 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.

10. Antisweat heater controls shall be configured to reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Light sources shall have an efficacy of not less than 40 lumens per Watt, including any ballast losses, or shall be provided with a device that automatically turns off the lights within 15 minutes of when the walk-in cooler or walk-in freezer was last occupied.

C403.10.2.1 Performance standards (Mandatory). Effective January 1, 2020, walk-in coolers and walk-in freezers shall meet the requirements of Tables C403.10.2.1(1), C403.10.2.1(2) and C403.10.2.1(3).

C403.10.3 Refrigerated display cases (Mandatory). Site-assembled or site-constructed refrigerated display cases shall comply with the following:

1. Lighting and glass doors in refrigerated display cases shall be controlled by one of the following:
   1.1. Time-switch controls to turn off lights during nonbusiness hours. Timed overrides for display cases shall turn the lights on for up to 1 hour and shall automatically time out to turn the lights off.
   1.2. Motion sensor controls on each display case section that reduce lighting power by not less than 50 percent within 3 minutes after the area within the sensor range is vacated.

2. Low-temperature display cases shall incorporate temperature-based defrost termination control with a time-limit default. The defrost cycle shall terminate first on an upper temperature limit breach and second upon a time limit breach.

3. Antisweat heater controls shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

C403.11.1 Duct and plenum insulation and sealing (Mandatory). Supply and return air ducts and plenums shall be insulated with not less than R-6 insulation where located in unconditioned spaces and where located outside the building with not less than R-8 insulation in Climate Zones 1 through 4 and not less than R-12 insulation in Climate Zones 5 through 8. Where located within a building envelope assembly, the duct or plenum shall be separated from the building exterior or unconditioned or exempt spaces by not less than R-8 insulation in Climate Zones 1 through 4 and not less than R-12 insulation in Climate Zones 5 through 8.

Exceptions:
1. Where located within equipment.
2. Where the design temperature difference between the interior and exterior of the duct or plenum is not greater than 15°F (8°C).

Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with Section 603.9 of the International Mechanical Code.

C403.11.2 Duct construction (Mandatory). Ductwork shall be constructed and erected in accordance with the International Mechanical Code.

C403.11.2.1 Low-pressure duct systems (Mandatory). Longitudinal and transverse joints, seams and connections of supply and return ducts operating at a static pressure less than or equal to 2 inches water gauge (w.g.) (498 Pa) shall be securely fastened and sealed with welds, gaskets, mastics (adhesives), mastic-plus-embedded-fabric systems or tapes installed in accordance with the manufacturer’s instructions. Pressure classifications specific to the duct system shall be clearly indicated on the construction documents in accordance with the International Mechanical Code.

Exception: Locking-type longitudinal joints and seams, other than the snap-lock and button-lock types, need not be sealed as specified in this section.

C403.11.2.2 Medium-pressure duct systems (Mandatory). Ducts and plenums designed to operate at a static pressure greater than 2 inches water gauge (w.g.) (498 Pa) but less than 3 inches w.g. (747 Pa) shall be insulated and sealed in accordance with Section C403.11.1. Pressure classifications specific to the duct system shall be clearly indicated on the construction documents in accordance with the International Mechanical Code.

C403.11.2.3 High-pressure duct systems (Mandatory). Ducts and plenums designed to operate at static pressures equal to or greater than 3 inches water gauge (747 Pa) shall be insulated and sealed in accordance with Section C403.11.1. In addition, ducts and plenums shall be leak tested in accordance with the SMACNA HVAC Air Duct Leakage Test Manual and shown to have a rate of air leakage (CL) less than or equal to 4.0 as determined in accordance with Equation 4-8.

\[ CL = \frac{F}{P^{0.65}} \]

where:

\[ F = \text{The measured leakage rate in cfm per 100 square feet of duct surface.} \]

\[ P = \text{The static pressure of the test.} \]

Documentation shall be furnished by the designer demonstrating that representative sections totaling not less than 25 percent of the duct area have been tested and that all tested sections comply with the requirements of this section.

C403.11.3 Piping insulation (Mandatory). Piping serving as part of a heating or cooling system shall be thermally insulated in accordance with Table C403.11.3.

Exceptions:

1. Factory-installed piping within HVAC equipment tested and rated in accordance with a test procedure referenced by this code.
2. Factory-installed piping within room fan-coils and unit ventilators tested and rated according to AHRI 440 (except that the sampling and variation provisions of Section 6.5 shall not apply) and AHRI 840, respectively.
3. Piping that conveys fluids that have a design operating temperature range between 60°F (15°C) and 105°F (41°C).
4. Piping that conveys fluids that have not been heated or cooled through the use of fossil fuels or electric power.
5. Strainers, control valves, and balancing valves associated with piping 1 inch (25 mm) or less in diameter.
6. Direct buried piping that conveys fluids at or below 60°F (15°C).

C403.11.3.1 Protection of piping insulation (Mandatory). Piping insulation exposed to the weather shall be protected from damage, including that caused by sunlight, moisture, equipment maintenance and wind, and shall provide shielding from solar radiation that can cause degradation of the material. Adhesive tape shall not be permitted.

C403.12 Mechanical systems located outside of the building thermal envelope (Mandatory). Mechanical systems providing heat outside of the thermal envelope of a building shall comply with Sections C403.12.1 through C403.12.3.

SECTION C404
SERVICE WATER HEATING (MANDATORY)

C404.9 Energy consumption of pools and permanent spas (Mandatory). The energy consumption of pools and permanent spas shall be controlled by the requirements in Sections C404.9.1 through C404.9.3.

C404.10 Energy consumption of portable spas (Mandatory). The energy consumption of electric-powered portable spas shall be controlled by the requirements of APSP 14.

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption. Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2.

C405.2 Lighting controls (Mandatory). Lighting systems shall be provided with controls that comply with one of the following.

1. Lighting controls as specified in Sections C405.2.1 through C405.2.6.
2. Luminaire level lighting controls (LLLC) and lighting controls as specified in Sections C405.2.1, C405.2.4 and C405.2.5. The LLLC luminaire shall be independently capable of:
   2.1. Monitoring occupant activity to brighten or dim lighting when occupied or unoccupied, respectively.
   2.2. Monitoring ambient light, both electric light and daylight, and brighten or dim artificial light to maintain desired light level.
   2.3. For each control strategy, configuration and reconfiguration of performance parameters including; bright and dim setpoints, timeouts, dimming fade rates, sensor sensitivity adjustments, and wireless zoning configurations.

Exceptions: Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted.
2. Interior exit stairways, interior exit ramps and exit passageways.
3. Emergency egress lighting that is normally off.

**C405.3 Interior lighting power requirements (Prescriptive).** A building complies with this section where its total connected interior lighting power calculated under Section C405.3.1 is not greater than the interior lighting power allowance calculated under Section C405.3.2.

**C405.4 Exterior lighting power requirements (Mandatory).** The total connected exterior lighting power calculated in accordance with Section C405.4.1 shall be not greater than the exterior lighting power allowance calculated in accordance with Section C405.4.2.

**C405.4.3 Gas lighting (Mandatory).** Gas-fired lighting appliances shall not be equipped with continuously burning pilot ignition systems.

**C405.5 Dwelling electrical meter (Mandatory).** Each dwelling unit located in a Group R-2 building shall have a separate electrical meter.

**C405.6 Electrical transformers (Mandatory).** Low-voltage dry-type distribution electric transformers shall meet the minimum efficiency requirements of Table C405.6 as tested and rated in accordance with the test procedure listed in DOE 10 CFR 431. The efficiency shall be verified through certification under an approved certification program or, where a certification program does not exist, the equipment efficiency ratings shall be supported by data furnished by the transformer manufacturer.

**Exceptions:** The following transformers are exempt:

2. Transformers that meet the *Energy Policy Act of 2005* exclusions that are not to be used in general purpose applications based on information provided in DOE 10 CFR 431.
3. Transformers that meet the *Energy Policy Act of 2005* exclusions with multiple voltage taps where the highest tap is not less than 20 percent more than the lowest tap.
4. Drive transformers.
5. Rectifier transformers.
6. Auto-transformers.
7. Uninterruptible power system transformers.
8. Impedance transformers.
9. Regulating transformers.
10. Sealed and nonventilating transformers.
12. Welding transformers.

**C405.7 Electric (Mandatory).** Electric motors shall meet the minimum efficiency requirements of Tables C405.7(1) through C405.7(4) when tested and rated in accordance with the DOE 10 CFR 431. The efficiency shall be verified through certification under an approved certification program or, where a certification program does not exist, the equipment efficiency ratings shall be supported by data furnished by the motor manufacturer.

**Exception:** The standards in this section shall not apply to the following exempt electric motors:

1. Air-over electric motors.
2. Component sets of an electric motor.
3. Liquid-cooled electric motors.
4. Submersible electric motors.
5. Inverter-only electric motors.

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R102.1.1 (IRC N1101.4) Above code programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy-efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy-efficiency program shall be considered to be in compliance with this code. The requirements identified as “mandatory” in Chapter 4 Table R405.2 shall be met.

R401.2 (IRC N1101.13) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory”
3. The energy rating index (ERI) approach in Section R406.

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall indicate the predominant R-values of insulation installed in or on ceilings, roofs, walls, foundation components such as slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces; U-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing performed on the building. Where there is more than one value for each component, the certificate shall indicate the value covering the largest area. The certificate shall indicate the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters.

R402.1 (IRC N1102.1) General (Prescriptive). The building thermal envelope shall comply with the requirements of Sections R402.1.1 through R402.1.5.

Exceptions:

1. The following low-energy buildings, or portions thereof, separated from the remainder of the building by building thermal envelope assemblies complying with this section shall be exempt
from the building thermal envelope provisions of Section R402.
1.1. Those with a peak design rate of energy usage less than 3.4 Btu/h · ft² (10.7 W/m²) or 1.0 watt/ft² of floor area for space-conditioning purposes.
1.2. Those that do not contain conditioned space.
2. Log homes designed in accordance with ICC 400.

R402.2 (IRC N1102.2) Specific insulation requirements (Prescriptive). In addition to the requirements of Section R402.1, insulation shall meet the specific requirements of Sections R402.2.1 through R402.2.13.

R402.3 (IRC N1102.3) Fenestration (Prescriptive). In addition to the requirements of Section R402, fenestration shall comply with Sections R402.3.1 through R402.3.5.

R402.4 (IRC N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

R402.5 (IRC N1102.5) Maximum fenestration U-factor and SHGC (Mandatory). The area-weighted average maximum fenestration U-factor permitted using tradeoffs from Section R402.1.5 or R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 in Climate Zones 1 through 3 shall be 0.50.

R403.1 (IRC N1103.1) Controls (Mandatory). Not less than one thermostat shall be provided for each separate heating and cooling system.

R403.1.2 (IRC N1103.1.2) Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation when the heat pump compressor can meet the heating load.

R403.3.1 (IRC N1103.3.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

R403.3.2 (IRC N1103.3.2) Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.
2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located
entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

2. Postconstruction test: Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

R403.3.5 (IRC N1103.3.5) Building cavities (Mandatory). Building framing cavities shall not be used as ducts or plenums.

R403.4 (IRC N1103.4) Mechanical system piping insulation (Mandatory). Mechanical system piping capable of carrying fluids greater than 105°F (41°C) or less than 55°F (13°C) shall be insulated to an R-value of not less than R-3.

R403.5.1 (IRC N1103.5.1) Heated water circulation and temperature maintenance systems (Mandatory). Heated water circulation systems shall be in accordance with Section R403.5.1.1. Heat trace temperature maintenance systems shall be in accordance with Section R403.5.1.2. Automatic controls, temperature sensors and pumps shall be accessible. Manual controls shall be readily accessible.

R403.5.3 (IRC N1103.5.3) Hot water pipe insulation (Prescriptive). Insulation for hot water piping with a thermal resistance, R-value, of not less than R-3 shall be applied to the following:

1. Piping 3/4 inch (19.1 mm) and larger in nominal diameter.
2. Piping serving more than one dwelling unit.
3. Piping located outside the conditioned space.
4. Piping from the water heater to a distribution manifold.
5. Piping located under a floor slab.
7. Supply and return piping in recirculation systems other than demand recirculation systems.

R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory). The building shall be provided with ventilation that complies with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

R403.7 (IRC N1103.7) Equipment sizing and efficiency rating (Mandatory). Heating and cooling equipment shall be sized in accordance with ACCA Manual S based on building loads calculated in accordance with ACCA Manual J or other approved heating and cooling calculation methodologies. New or replacement heating and cooling equipment shall have an efficiency rating equal to or greater than the minimum required by federal law for the geographic location where the equipment is installed.

R403.8 (IRC N1103.8) Systems serving multiple dwelling units (Mandatory). Systems serving multiple

R403.9 (IRC N1103.9) Snow melt and ice system controls (Mandatory). Snow- and ice-melting systems, supplied through energy service to the building, shall include automatic controls capable of shutting off the system when the pavement temperature is greater than 50°F (10°C) and precipitation is not falling, and an automatic or manual control that will allow shutoff when the outdoor temperature is greater than 40°F (4.8°C).

R403.10 (IRC N1103.10) Pools and permanent spa energy consumption (Mandatory). The energy consumption of pools and permanent spas shall be in accordance with Sections R403.10.1 through R403.10.3.

R403.11 (IRC N1103.11) Portable spas (Mandatory). The energy consumption of electric-powered portable spas shall be controlled by the requirements of APSP-14.

R404.1 (IRC N1104.1) Lighting equipment (Mandatory). Not less than 90 percent of the permanently installed lighting fixtures shall contain only high-efficacy lamps.

R404.1.1 (IRC N1104.1.1) Lighting equipment (Mandatory). Fuel gas lighting systems shall not have continuously burning pilot lights.

SECTION R405 (N1105)
SIMULATED PERFORMANCE ALTERNATIVE (PERFORMANCE) TOTAL BUILDING PERFORMANCE

R405.1 (IRC N1105.1) Scope. This section establishes criteria for compliance using simulated energy performance analysis. Such analysis shall include heating, cooling, mechanical ventilation and service water heating energy only.

R405.2 (IRC N1105.2) Mandatory requirements. Performance Based Compliance. Compliance with this section, based on total building performance, requires that the mandatory provisions identified in Section R401.2 be met. A proposed design meets all of the following:

1. The requirements of the sections indicated within Table R405.2
2. Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.
3. An annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Data System Prices and Expenditures reports. Code officials shall be permitted to require time-of-use pricing in energy cost calculations.

Exception: The energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

TABLE R405.2 (IRC N1105.2)
REQUIREMENTS FOR TOTAL BUILDING PERFORMANCE
§ Reference to a code section includes all the relative subsections except as indicated in the table.

Delete without substitution:

**R405.3 Performance-based compliance.** Compliance based on simulated energy performance requires that a proposed residence (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official such as the Department of Energy, Energy Information Administration’s State Energy Data System Prices and Expenditures reports. Code officials shall be permitted to require time-of-use pricing in energy cost calculations.

**Exception:** The energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

Revise as follows:

**SECTION R406 (IRC N1106) ENERGY RATING INDEX COMPLIANCE ALTERNATIVE**

**R406.1 (IRC N1106.1) Scope.** This section establishes criteria for compliance using an Energy Rating Index (ERI) analysis.

Delete and substitute as follows:
R406.2 Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.

**Exception:** Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

R406.2 ERI Compliance Compliance based on the Energy Rating Index requires that the rated design meets all of the following:

1. The requirements of the sections indicated within Table R406.2
2. Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.
3. Maximum energy rating index of Table R406.4

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4 the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

Reason: No technical changes are intended. No advantage to any proprietary interests governed by the code is intended. The intent is strictly to make the IECC more understandable and easier to use, as explained below.

The labels “prescriptive” and “mandatory” are found in the IECC but they are not used consistently and no direction is provided for the intended application of the provisions with such labels. These terms are applied to various section and subsection titles throughout the IECC creating confusion for users of the code. The SEHPCAC reviewed every section of the IECC with the goal of simplifying the code by removing ‘mandatory’ and ‘prescriptive’ labels and finding a better way to communicate distinctions for what is required between the performance and prescriptive paths of the code.

The labels are not requirements and are not enforceable. It is SEHPCAC’s understanding that ‘mandatory’ was intended to mean ‘non-tradeable’ when using performance compliance options, meaning that where the procedures or systems described within the ‘mandatory’ section are included as part of the design, the requirements of that section must be met and it cannot be traded off. “Prescriptive”, on the other hand, was intended to mean “mandatory” when using the prescriptive path, but “tradeable” when using the performance path.
‘Mandatory’ requirements for the Total Building Performance compliance alternative as they are currently found in the code are identified and made enforceable by the charging language in R401.2 (2) and by reference from R405.2 (Mandatory requirements). “Mandatory” requirements for the Energy Rating Index compliance alternative as they are currently found in the code are identified and made enforceable by the charging language in R406.2 (Mandatory requirements).

This proposal borrows a formatting concept from the City of Seattle using a tabular approach to clearly identify the sections that are non-tradeable (‘mandatory’) when complying with either of the performance compliance alternatives. Proposed new Table R405.2 lists the section references to all required (‘mandatory’) measures for this specific compliance path, and proposed new Table R406.2 lists the section references to all required (“mandatory”) measures for that specific compliance path. (An identical treatment of the performance path is also being proposed for the IECC-C to maintain consistent application and formatting).

The non-tradeable sections that populate the proposed new Tables R405.2 and R406.2 were identified using the following criteria:

- The section was specifically identified as a mandatory requirement by R401.2 (2) or R406.2.
- The subsection was specifically labeled ‘mandatory’ in the body of the code (e.g. R403.3.2) even though the parent section was not (R403.3) and other companion subsections were not (e.g. R403.3.1)
- For subsections, the parent section was labeled ‘mandatory’ and no subsection was labeled otherwise (e.g. R402.4)
- Compliance was required by reference to another code (e.g. R402.1.1)

Where all of a section has been identified as mandatory (e.g. R402.4), just that section number is listed in the table; a tabular footnote explains that all relative subsections are included.

Where subsections are identified as ‘prescriptive,’ (e.g. R403.3.1), but the parent section or associated subsections are identified as ‘mandatory’ (e.g. R403.3.2), an exception is provided for the ‘prescriptive’ subsection in new Tables R405.2 and R406.2 to make clear which subsections apply in each performance compliance alternative.

This reason statement includes a discussion version of new Tables R405.2/R406.2 that features an additional column which identifies what criteria were used to establish the related section’s presence in the table. This additional column is not actually proposed for inclusion in the code and is merely for the convenience of the reviewers of the proposal.

Note that the discussion version of new Tables R405.2/R406.2 also features expanded rows (e.g. the R402.4 series) to identify the relevant criteria used to validate their inclusion in the new tables.

Adoption of new Tables R405.2 and R406.2 means that the R401.2 (2) and R406.2 laundry lists of mandatory requirements are no longer needed and that all ‘mandatory’ and ‘prescriptive’ labels are no longer needed.

Note that a number of the sections that the SEHPCAC reviewed did not meet the preceding criteria for populating new Tables R405.2 and R406.2 because they were not clearly ‘prescriptive’ or tradeable. Those sections are not proposed to be added to either new table as part of this proposal. Instead, those sections are proposed to be added to the new tables through separate individual code changes. SEHPCAC has simply called out these provisions to aid the committee’s and membership’s decision as to whether any of those individual sections is actually ‘mandatory’ or non-tradeable and appropriate for inclusion in new Tables R405.2 and R406.2.
Finally, a modification to Section R102.1.1 is required with the elimination of the labels identifying “mandatory” provisions.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IGCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is a restructing of information on mandatory provisions, not change to the provisions themselves

Proposal # 4423

CE42-19 Part II
CE43-19
IECC: C401.2, Chapter 6CE (New)

Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of ANSI/ASHRAE 90.4 for Data Centers.
3. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
4. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

Add new text as follows:

ASHRAE

90.4-16: Energy Standard for Data Centers-

Reason: ASHRAE Standard 90.4, Energy Standard for Data Centers, was published in 2016 and is on continuous maintenance. It establishes the minimum energy efficiency requirements of data centers for design and construction and for creation of a plan for operation and maintenance, and for utilization of on-site or off-site renewable energy resources.

Data center applications are unlike their commercial building counterparts in two significant ways. First, they include significantly higher plug loads (e.g., computer servers and UPS equipment). Second, they employ rapidly changing technology for the IT equipment and associated power/cooling approaches.

There is also a recognition that current industry modeling tools do not possess all the necessary mathematical models to accurately and appropriately model data center HVAC and electrical equipment design. As a result, demonstrating compliance to the 90.1 Chapter 11 or energy cost budget (ECB) approaches is usually impractical.

Along with ASHRAE 90.1, designers and owners of data centers should have the option to use ANSI/ASHRAE 90.4 as a compliance path.

Cost Impact: The code change proposal will increase the cost of construction. This proposal increases the costs of data centers due to its higher efficiency requirements.

Analysis: A review of the standard proposed for inclusion in the code, ASHRAE 90.4, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Energy Conservation Code

Revise as follows:

C401.1 Scope. The provisions in this chapter are applicable to commercial buildings and their building sites.

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
   **Exception:** Dwelling units and sleeping units in Group R-2 buildings shall be deemed to be in compliance with this chapter provided they comply with the Energy Rating Index (ERI) Compliance Alternative in Section R406.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

Update standard(s) as follows:

RESNET

**Reason:** Multifamily buildings (Group R-2) have historically been split between the residential and commercial provisions of the IECC, based on their height, resulting in very different compliance requirements for similar buildings. Prior change proposals seeking to provide consistency for this building type have struggled to find a simple approach. This proposal provides a simple optional alternative for dwelling and sleeping units within these “commercial buildings” to instead meet the same energy efficiency requirements of dwelling and sleeping units under the Residential provisions, specifically section R406, the Energy Rating Index Compliance Alternative. This section R406 still requires compliance with mandatory items, including but not limited to those listed in sections R401 through R404. The other spaces in the building, such as corridors, stairwells, lobbies, community spaces, and sometimes, retail, still are required to comply with the commercial provisions. While this proposal was not possible before now, ANSI/RESNET/ICC 301-2019, which is the Standard for calculating the ERI, has recently expanded its scope to include dwelling and sleeping units in any height building, which means those units in ‘commercial buildings’ are now eligible for an ERI. While efficiency requirements can vary for the same building components, whether you are in the Residential or Commercial provisions, this is is the 1st step in providing dwelling units in multifamily buildings the same path to code compliance, regardless of their building.
height. This results in a dwelling unit in a 3 story building and the same exact dwelling unit in a 4 story building
to both be deemed code compliant, with the same exact building components.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The cost impact depends on the code compliance currently being followed.

For those doing building simulations in accordance with C407, this may present a decrease in the costs to
demonstrate compliance.

Those not choosing this alternative will experience no change in costs.

Those choosing this alternative will likely do so if they are able to utilize the same energy rating index being
used in other multifamily programs, such as ENERGY STAR and LEED, or utility-sponsored incentive programs
that require an ERI, as their code compliance option. This will also therefore result in no additional costs.
2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to 85 percent of the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

Exception: Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

Reason: The third compliance option in C401.2 is for the total building performance compliance method and requires that the energy cost of the proposed design is less than or equal to 85% of the energy cost of the standard reference design, and requires compliance with C407 (and other sections). However, C407 only requires that the energy cost of the proposed design is less than or equal to the energy cost of the standard reference design. This proposal removes this apparent conflict by moving the 85% requirement to be only in C407. This is a more appropriate section for this requirement since C401.2 is a general section that should just give the required sections that must be complied with for each compliance option. There is no technical change intended by this proposal.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This proposal is only a clarification so there is no change to the cost of construction.
CE46-19
IECC: C401.2, C407.2, C407.3, C407.7 (New)

Proponent: Andrew Klein, representing Self Storage Association (andrew@asklein.com)

2018 International Energy Conservation Code
Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.
4. The requirements of Sections C407 and C408. The building energy cost shall not exceed 0 percent of the standard reference design building.

C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.

Exception: Buildings and building sites complying with Item 4 of Section C401.2.

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

Exceptions:

1. Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.
2. When complying with Item 4 of Section C401.2, the reduction in energy cost of the proposed design associated with on-site renewable energy shall not be limited to 5 percent of the total energy cost.

Add new text as follows:

C407.7 Onsite energy storage. Compliance with Item 4 of Section C401.2 requires an onsite energy storage system with a usable capacity greater than or equal to 1/730 of the annual building energy use calculated without the contribution of on-site renewable energy.

Reason: The purpose of the IECC is the reduction of building energy use for two overall philosophical purposes: (1) reducing strain on infrastructure so that new power plants do not need to be built and (2) the
reduction of greenhouse gas emissions.
The elimination of “backstops” (e.g., minimum insulation levels, minimum equipment efficiency, etc.) is balanced
with the net-zero energy requirement and the 12-hour energy storage requirement. Buildings of certain uses
have shown success utilizing this net-zero energy approach, with as little as 5-year paybacks for equipment
cost.

20 years in the future, when it comes time to begin replacing renewable power generators and storage systems,
equipment will be even more efficient, more affordable, and more mainstream.

This approach will spur new designs and technology development that will fast track us in meeting our two
overall philosophical goals: reduced grid infrastructure costs and zero greenhouse gas emissions.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This Code Change Proposal provides an alternative path.

Proposal # 5362

CE46-19
Add new definition as follows:

**ZERO ENERGY PERFORMANCE INDEX (zEPI2004).** A value representative of the ratio of energy performance based on the proposed design compared to the average energy performance of a comparative baseline building (ASHRAE 90.1-2004) and its site.

**SECTION C401**

**GENERAL**

**C401.1 Scope.** The provisions in this chapter are applicable to commercial buildings and their building sites.

Revise as follows:

**C401.2 Application.** Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.
4. The requirements of Section C408 to achieve near-net zero energy performance.

Add new text as follows:

**C408**

**Near Net-Zero Energy Performance**

**C408.1 Near Net-Zero Energy Performance** Performance-based designs shall demonstrate a zEPI2004 of 30 or below as determined in accordance with Equation xxx-1.

\[
zEPI_{2004} = 75 \times \frac{\text{Proposed building performance}}{\text{Baseline building performance}} \quad (\text{Equation xxx-1})
\]

where:

Proposed building performance = The proposed building performance in source kBtu for the proposed design of the building and its site calculated in accordance with Section C408.1.1.
Baseline building performance = The baseline building performance in source kBtu for a baseline building and its site in accordance with Section C408.1.1.

75 = a fixed value representing the performance of a baseline building designed to comply with ASHRAE 90.1-2004.

**C408.1.1 Modeling methodology** The proposed building performance and the baseline building performance of the building and building site shall be calculated in accordance with Appendix G to ASHRAE 90.1, as modified by Sections C408.1.1.1 and C408.1.1.2. The energy use modeling shall include all energy used for building and site functions and anticipated occupancy.

**C408.1.1.1 Energy units** The building performance calculations in Section G3 of ASHRAE 90.1 shall be based on energy use instead of energy cost. Energy use shall be converted to consistent units by multiplying the nonrenewable energy fossil fuel use at the utility meter or measured point of delivery to Btus and multiplying by the conversion factor in Table C408.1.1.1 based on the geographical location of the building.

Revise as follows:

**C105.2.6 Final inspection.** The final inspection shall include verification of the installation and proper operation of all required building controls, and documentation verifying activities associated with required building commissioning have been conducted in accordance with Section C408. C409.

**C402.5.7 Vestibules.** Building entrances shall be protected with an enclosed vestibule, with all doors opening into and out of the vestibule equipped with self-closing devices. Vestibules shall be designed so that in passing through the vestibule it is not necessary for the interior and exterior doors to open at the same time. The installation of one or more revolving doors in the building entrance shall not eliminate the requirement that a vestibule be provided on any doors adjacent to revolving doors.

**Exceptions:** Vestibules are not required for the following:

2. Doors not intended to be used by the public, such as doors to mechanical or electrical equipment rooms, or intended solely for employee use.
3. Doors opening directly from a sleeping unit or dwelling unit.
4. Doors that open directly from a space less than 3,000 square feet (298 m²) in area.
5. Revolving doors.
6. Doors used primarily to facilitate vehicular movement or material handling and adjacent personnel doors.
7. Doors that have an air curtain with a velocity of not less than 6.56 feet per second (2 m/s) at the floor that have been tested in accordance with ANSI/AMCA 220 and installed in accordance with the manufacturer’s instructions. Manual or automatic controls shall be provided that will operate the air curtain with the opening and closing of the door. Air curtains and their controls shall comply with Section C408.2.3. C409.2.3.

**C406.4 Enhanced digital lighting controls.** Interior lighting in the building shall have the following enhanced...
lighting controls that shall be located, scheduled and operated in accordance with Section C405.2.2.

1. Luminaires shall be configured for continuous dimming.
2. Luminaires shall be addressed individually. Where individual addressability is not available for the luminaire class type, a controlled group of not more than four luminaries shall be allowed.
3. Not more than eight luminaires shall be controlled together in a daylight zone.
4. Fixtures shall be controlled through a digital control system that includes the following function:
   4.1. Control reconfiguration based on digital addressability.
   4.2. Load shedding.
   4.3. Individual user control of overhead general illumination in open offices.
   4.4. Occupancy sensors shall be capable of being reconfigured through the digital control system.
5. Construction documents shall include submittal of a Sequence of Operations, including a specification outlining each of the functions in Item 4.
6. Functional testing of lighting controls shall comply with Section C408-C409.

SECTION C408-C409
MAINTENANCE INFORMATION AND SYSTEM COMMISSIONING

Add new standard(s) as follows:

ASHRAE

Reason: This proposal adds a compliance option for projects or jurisdictions striving for a near net-zero energy performance metric.

The zEPI methodology was created by Charles Eley and first introduced to codes in the International Green Construction Code. It served as a means of calculating energy performance modeling that would simplify the ability of moving the IgCC energy performance target to net zero energy within several code cycles. With the technical content of the IgCC now being developed by ASHRAE 189.1, this unique approach has been lost.

zEPI points to a unit on a scale that goes from a theoretical 100 to zero, where 100 equals actual performance for existing buildings as identified in the 2003 CBECS database. The 75 on that scale is a fixed number representing the energy performance level of the ASHRAE 90.1-2004, which is the baseline model using ASHRAE Appendix G.

The zEPI target in this proposal is 30 or below, which represents an energy performance level that is 70% better in terms of energy efficiency/conservation than a 2013 CBECS building. Based on data from many built "net zero" and Passive House buildings, 30 is a reasonable target for the building envelope and systems, where the remaining energy consumed by the building can be accommodated with on-site renewables in many climate and insolation zones.

The section has been added to Chapter CE 4 as Section C408, renumbering the existing C408 (Maintenance Information and System Commissioning) and all related subsections to C409. References to this section have been edited accordingly.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

It is a compliance option for projects or jurisdictions seeking a higher level of energy performance than the base
code. Even if selected, many projects have been designed and built using a near net-zero energy goal at no increase in cost over conventional energy performance goals.

**Analysis:** The referenced standard, ASHRAE 90.1-2004 was previously referenced in the 2006 edition of the IECC, but is not currently referenced in other 2018 I-codes.
CE48-19

IECC: C401.2, C407.2

Proponent: David Renn, PE, SE, City and County of Denver, representing Code Change Committee of Colorado Chapter of ICC (david.renn@denvergov.org)

2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405.

Reason: This proposal is intended to simplify the code by providing mandatory requirements of the Total Building Performance method in one location only. Currently, the third compliance method in the general application section C401.2 lists all of the mandatory sections that are required for the Total Building Performance method, and also requires compliance with C407 and C408. Then, these same mandatory sections are given in C407.2. There is no need to have these requirements in the code in two locations and this proposal locates them only as a specific requirement of the C407 for the Total Building Performance method. By giving these requirements in one location only, it reduces the risk of changes being made in one section without updating the other section.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal is a simplification of the code without any technical change, so cost of construction will not change.

Proposal # 4149
**CE49-19**

**IECC: C401.2, C407.3**

**Proponent:** William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

### 2018 International Energy Conservation Code

Revise as follows:

**C401.2 Application.** Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 80 percent of the standard reference design building.

**C407.3 Performance-based compliance.** Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to 80 percent of the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s *State Energy Price and Expenditure Report*. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

**Exception:** Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

**Reason:** The purpose of this code change proposal is to improve the efficiency of buildings designed to comply under the IECC performance path by altering the multiplier for the standard reference design building from 85% to 80%. Starting with the 2012 IECC, rather than undertake a complete retooling of the performance path, advocates added a percentage multiplier to the standard reference design to reduce the energy budget for the baseline. This approach provided maximum flexibility to the code user. Improvements could be made to any part of the building to achieve the 15% improvement. This approach also established a means of easily updating the performance path in the future: As additional efficiency is needed, the multiplier can be lowered to meet those needs.

Since the 2012 IECC, the 85% multiplier has not been changed, even though other parts of the commercial IECC have undergone improvements. This proposal updates the multiplier by essentially improving efficiency by about 5% (as compared to the original baseline code, the 2009 IECC).

This proposal also includes the same multiplier in Section C407.3. We believe this is a more appropriate place for the multiplier, since it is closer to the other assumptions included in the standard reference design. However, we would prefer to see it included in both C407.3 and C401.2 to make sure that code users understand the requirements of the performance path.
Cost Impact: The code change proposal will increase the cost of construction. Adding additional efficiency measures will increase construction cost. However, we expect that design professionals and builders will select the improvements that are the most cost-effective and the easiest to implement into specific designs.
CE50-19

IECC: C401.2.1, C402.4.3.4

Proponent: Thomas D. Culp, Ph.D., Birch Point Consulting LLC, representing the Glazing Industry Code Committee and the Aluminum Extruders Council (culp@birchpointconsulting.com)

2018 International Energy Conservation Code

Revise as follows:

C401.2.1 Application to replacement fenestration products. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for U-factor and SHGC in Table C402.4.

Exception: An area-weighted average of the U-factor of replacement fenestration products being installed in the building for each fenestration product category listed in Table C402.4 shall be permitted to satisfy the U-factor requirements of Table C402.4. The combined area-weighted average U-factor calculated using the respective area for each fenestration product category listed in Table C402.4. Individual fenestration products from different product categories listed in Table C402.4 shall not be combined in calculating the area-weighted average U-factor, equal to or less than the combined area-weighted average U-factor calculated using the U-factors from Table C402.4 with the same fenestration area and product types.

C402.4.3.4 Area-weighted U-factor. An area-weighted average shall be permitted to satisfy the U-factor requirements of Table C402.4. The combined area-weighted average U-factor calculated using the respective area for each fenestration product category listed in Table C402.4. Individual fenestration products from different fenestration product categories listed in Table C402.4 shall not be combined in calculating area-weighted average U-factor, equal to or less than the combined area-weighted average U-factor calculated using the U-factors from Table C402.4 with the same fenestration area and product types.

Reason: The purpose of this proposal is to clarify the area-weighted averaging of U-factor for fenestration products and make it consistent with other parts of the code. The current language includes a sentence that says fenestration products from different product categories listed in Table C402.4 shall not be combined in area-weighted averages, such as fixed and operable windows. However, this is inconsistent with other parts of the code. Section C402.1.5 permits it through Factor A of Equation 4-2 for the commercial energy code, and Sections R402.1.5 and R402.3.1 permit it for fenestration and all envelope components in the residential energy code. Furthermore, there is no technical reason they should not be combined for calculating area-weighted average U-factor.

As a practical example, in curtain wall, higher U-factors of operable commercial awning/vent products can be compensated for by lower U-factors of the main fixed window area, with the same overall performance of the facade. If this section is not corrected, it could inadvertently restrict flexibility for the designer, and also potentially discourage the use of operable products for natural ventilation, as casements and vents have a more difficult time complying with the prescriptive U-factors than sliding or fixed windows. Therefore, this proposal is necessary for practical considerations as well as clarification and consistency with other parts of the code. At the same time, this proposal also clarifies how the average is calculated and compared to the baseline prescriptive requirements. Finally, in response to public comments and discussion last cycle, this proposal does not include area-weighted averaging of SHGC.

(Note: if section C402.1.2.1 is moved to chapter 5 by other proposals, our intent is that the same changes in this proposal also be included in the section moved to chapter 5.)

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal simply clarifies the use of area-weighted averaging of fenestration product U-factors, and does
not impact cost of construction.

Revise as follows:

C401.2 C401.3 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections Section C407, C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

Delete without substitution:

C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.

Revise as follows:

SECTION C408

MAINTENANCE INFORMATION AND SYSTEM COMMISSIONING

(MANDATORY)

Proposal # 4702
CE51-19 Part II

IECC: R401.2 (IRC N1101.6) (New), R401.2 (IRC N1101.13), R405.2 (IRC N1105.2), R406.2 (IRC N1106.2)

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R401.1 Scope. This chapter applies to residential buildings.

Add new text as follows:

R401.2 (IRC N1101.6) Mandatory and Prescriptive Provisions labeled as "Mandatory" are required using any compliance option. Provisions labeled "Prescriptive" are only required when complying with Item 1 of Section R401.2. Charging section labels apply to unlabeled subsections.

Revise as follows:

R401.2 (IRC N1101.13) R401.3 (IRC N1101.14) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

R405.2 (IRC N1105.2) Mandatory requirements: Supply and Return Ducts (Mandatory). Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

R406.2 (IRC N1106.2) Thermal envelope (Mandatory requirements.) Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.

   Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

Reason: This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx (http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx)

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change makes no additions nor deletions to the technical provisions of the code and has no impact on design or construction.
CE52-19
IECC: C401.2.1, C402.4.3.4

Proponent: Tom Zaremba, Roetzel & Andress, representing Self (tzaremba@ralaw.com)

2018 International Energy Conservation Code

Revise as follows:

C401.2.1 Application to replacement fenestration products. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for U-factor and SHGC in Table C402.4.

Exception: An area-weighted average of the U-factor and SHGC of replacement fenestration products being installed in the building for each fenestration product category listed in Table C402.4 shall be permitted to satisfy the U-factor and SHGC requirements of Table C402.4. The combined area-weighted average U-factor calculated using the respective area for each fenestration product category listed in Table C402.4. Individual fenestration products from different product categories listed in Table C402.4 C402.4 shall be equal to or less than the combined area-weighted average U-factor calculated using the U factors from Table C402.4 with the same fenestration area and product types. Area-weighted average SHGC shall only be calculated for vertical fenestration facing within 45 degrees of each cardinal direction and shall be equal to or less than the area-weighted average SHGC calculated using the SHGC from Table C402.4 with the same fenestration area and orientation. Vertical fenestration and skylights shall not be combined in calculating the area-weighted average U-factor SHGC.

C402.4.3.4 Area-weighted U-factor factor and SHGC. An area-weighted average shall be permitted to satisfy the U-factor and SHGC requirements of Table C402.4. The combined area-weighted average U-factor calculated using the respective area for each fenestration product category listed in Table C402.4. Individual fenestration products from different fenestration product categories listed in Table C402.4 C402.4 shall be equal to or less than the combined area-weighted average U-factor calculated using the U-factors from Table C402.4 with the same fenestration area and product types. Area-weighted average SHGC shall only be calculated for vertical fenestration facing within 45 degrees of each cardinal direction and shall be equal to or less than the area-weighted average SHGC calculated using the SHGC from Table C402.4 with the same fenestration area and orientation. Vertical fenestration and skylights shall not be combined in calculating area-weighted average U-factor SHGC.

Reason: This proposal clarifies the area-weighted averaging of fenestration product properties for prescriptive compliance, and provides consistency with other parts of the code. Last cycle, a similar proposal passed the code development committee by a vote of 11-1, but failed in the final vote as a result of misunderstanding about (a) how to calculate the baseline for comparison, and (b) how the SHGC of products facing different directions should be handled. Both of these concerns have been addressed in this proposal. Area-weighted averaging of U-factor of all fenestration products is already included in Section C402.1.5 through Factor A of Equation 4-2 for the commercial energy code, and in Sections R402.1.5 and R402.3.1 for the residential energy code, so it makes sense to allow averaging of all products here too. To address prior concerns, additional detail was added to the wording on how the area-weighted average U-factor is calculated and compared to the baseline prescriptive requirements.

For SHGC, Section R402.3.2 allows area-weighted averaging of SHGC of all products for the residential code. For the commercial code, the IECC code development body indicated in previous cycles that products facing different directions, e.g. north and west, should not be combined. However, there is no technical reason to not allow averaging of SHGC as long as it is limited by orientation and vertical vs. skylight. Therefore, SHGC averaging is included here, and to address concerns from last cycle, the wording was made more specific such
as only allowing products facing within 45 degrees of each cardinal direction to be combined.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal only addresses the option to use area-weighted averaging of fenestration product U-factors and SHGC, and does not impact cost of construction.
Renewable Energy Certificate (REC). An instrument that represents the environmental attributes of one megawatt-hour of renewable electricity; also known as an energy attribute certificate (EAC).

**C401.2.2 On-site renewable energy** Each building site shall have equipment for on-site renewable energy with a rated capacity of not less than 0.25 W/ft² (2.7 W/m²) multiplied by the sum of the gross conditioned floor area of the three largest floors. Documentation shall be provided to the code official that indicates that renewable energy certificates (RECs) associated with the on-site renewable energy will be retained and retired by or on behalf of the owner or tenant.

**Exceptions:**

1. Any building located where an unshaded flat plate collector oriented towards the equator and tilted at an angle from horizontal equal to the latitude receives an annual daily average incident solar radiation less than 3.5 kWh/m²·day (1.1 kBTu/ft²·day).
2. Any building where more than 80 percent of the roof area is covered by any combination of equipment other than for on-site renewable energy systems, planters, vegetated space, skylights or occupied roof deck.
3. Any building where more than 50 percent of roof area is shaded from direct-beam sunlight by natural objects or by structures that are not part of the building for more than 2,500 annual hours between 8:00 AM and 4:00 PM.

**Revise as follows:**

**C406.5 On-site renewable energy.** The total minimum ratings of on-site renewable energy systems, not including on-site renewable energy system capacity used for compliance with Section C401.2.2, shall be one of the following:

1. Not less than 1.71 Btu/h per square foot (5.4 W/m²) or 0.50 watts per square foot (5.4 W/m²) of conditioned floor area.
2. Not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

**Reason:** Onsite renewable energy installations are becoming widespread in many parts of the country, and mandatory in other parts. This proposal creates a mandatory requirement for a system that is approximately one-half of the capacity that has been a compliance package selection in Section 406 since the 2012 IECC. This language is largely based on Addendum “by” now pending to modify ASHRAE 90.1-2016. The three exceptions are written to ensure that the requirement is not being applied to buildings without adequate space on the roof, to buildings that are in areas of the country where unblocked insolation levels do not provide enough energy to make the equipment cost-effective (according to ASHRAE cost-effective criteria), and to buildings where solar access is wholly or partially blocked. The economic analysis supporting the Addendum is what was used to derive the specifications in the measure’s exceptions. The analysis included multi-variate calculations on the PNNL 3-Story Medium Office Bldg Prototype and modeled @ 0.25W/SF of renewable capacity for conditioned area on all 3 floors. The solar equipment on the prototype models passed the ASHRAE
Economic Scalar in 5 of 6 insolation zones. The sixth zone aligns with the third exception in the proposal.

Section 406.5 is modified so that the renewable capacity used for compliance with the new minimum requirement is not also counted towards compliance with Section 406.

The proposal also ensures that renewable energy used for compliance with another obligation (eg. through the transfer of RECs then applied to a state Renewable Portfolio Standard) is not double counted towards compliance with the IECC. While this proposal does not cite Green-E, the Green-E Standard describes how double counting occurs when RECs associated with an on-site system have been transferred to another party in the transaction for the onsite renewable system (such as a lease or financing contract) and are then counted towards code compliance:

*Examples of prohibited double uses include, but are not limited to:*

1) *When the same REC is sold by one party to more than one party, or any case where another party has a conflicting contract for the RECs or the renewable electricity;*

2) *When the same REC is claimed by more than one party, including any expressed or implied environmental claims made pursuant to electricity coming from a renewable energy resource, environmental labeling or disclosure requirements. This includes representing the energy from which RECs are derived as renewable in calculating another entity’s product or portfolio resource mix for the purposes of marketing or disclosure;*

3) *When the same REC is used by an electricity provider or utility to meet an environmental mandate, such as an RPS, and is also used to satisfy customer sales under Green-e Energy; or*

4) *Use of one or more attributes of the renewable energy or REC by another party. This includes when a REC is simultaneously sold to represent “renewable electricity” to one party, and one or more Attributes associated with the same MWh of generation (such as CO2 reduction) are also sold, to another party.*

**Bibliography:** Addendum by to Standard 90.1-2016, Energy Standard for Buildings Except Low-Rise Residential Buildings; ASHRAE, January 2018. (pending at the time of submittal)

**Cost Impact:** The code change proposal will increase the cost of construction

The representative average price for onsite renewable energy systems as analyzed in 2018 by the ASHRAE 90.1 working group was $2.50 per installed watt of capacity, before incentives. The workgroup also indicated that the required capacity levels were cost-effective, according to ASHRAE criteria, for buildings in the areas that were subject to the requirement (i.e. not excepted from the requirement).

ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1. 2.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.
4. Tropical zone alternative in C401.3

Add new text as follows:

C401.3 Tropical zone alternative. Group R-2 buildings in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level shall be deemed to be in compliance with this chapter where the conditions of either Section C401.3.1 or C401.3.2 are met.

C401.3.1.1 Limited air-conditioning option. Where a portion of the dwelling unit is provided with air-conditioning, all the following shall be met:

1. Not more than one-half of the occupied space is air conditioned.
2. The occupied space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in conditioned spaces has a solar heat gain coefficient of less than or equal to 0.30, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section R404.
6. The exterior roof surface complies with one of the options in Table C402.3 or the roof or ceiling has insulation with an R-value of R-15 or greater. Where attics are present, attics above the insulation are vented and attics below the insulation are unvented.
7. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
8. Operable fenestration provides a ventilation area of not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

C401.3.2 Dwelling units without air-conditioning option. Where none of the occupied space is air conditioned or heated, all of the following shall be met:

1. There are no requirements for glazing U-factor, SHGC or air tightness.
2. Permanently installed lighting is in accordance with Section R404.
3. The exterior roof and wall surfaces have an 0.85 initial and 0.70 aged reflectivity or have insulation with an R-value of R-5 or greater.
4. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
5. Operable fenestration provides ventilation in each room. There shall be at least one window per face of the dwelling unit.
6. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
7. Interior doors to bedrooms are capable of being secured in the open position.
8. Ceiling fans are provided in at least one bedroom and in the largest space that is not used as a bedroom.
2018 International Energy Conservation Code

R401.2 Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.
4. The tropical zone alternative in accordance with Section R401.2.1.

Revise as follows:

R401.2.1 (IRC N1101.13.1) Tropical zone. Residential buildings in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level shall be deemed to be in compliance with this chapter provided that where the following conditions of either Section R401.2.1.1 or R401.2.1.2 are met:

1. Not more than one-half of the occupied space is air conditioned.
2. The occupied space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in conditioned spaces has a solar heat gain coefficient of less than or equal to 0.40, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section R404.
6. The exterior roof surface complies with one of the options in Table C402.3 or the roof or ceiling has insulation with an R-value of R-15 or greater. Where attics are present, attics above the insulation are vented and attics below the insulation are unvented.
7. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
8. Operable fenestration provides a ventilation area of not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

R401.2.1.1 (IRC N1101.13.1.1) Limited air-conditioning option. Where a portion of the dwelling unit is provided with air-conditioning, all of the following shall be met:

1. Not more than one-half of the occupied space is air conditioned.
2. The occupied space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in conditioned spaces has a solar heat gain coefficient of less than or equal to 0.40, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section R404.
6. The exterior roof surface complies with one of the options in Table C402.3 or the roof or ceiling has insulation with an R-value of R-15 or greater. Where attics are present, attics above the insulation are vented and attics below the insulation are unvented.
vented and attics below the insulation are unvented.
7. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
8. Operable fenestration provides a ventilation area of not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

Add new text as follows:

R401.2.1.2 (IRC N1101.13.1.2) Dwelling units without air-conditioning option. Where none of the occupied space of the dwelling unit is air-conditioned or heated, all of the following shall be met:
1. There are no requirements for glazing U-factor, SHGC or air tightness.
2. Permanently installed lighting is in accordance with Section R404.
3. The exterior roof and wall surfaces shall have an 0.85 initial and 0.70 aged reflectivity or have insulation with an R-value of R-5 or greater.
4. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
5. Operable fenestration provides ventilation in each room. There shall be at least one window per face of the dwelling unit.
6. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
7. Interior doors to bedrooms are capable of being secured in the open position.
8. Ceiling fans are provided for a bedroom and the largest space that is not used as a bedroom.

Reason: This change provides a very low-income option which achieves energy savings primarily by having no air conditioning and no heating which yeilds a very low energy residence compared to the code home. This new option includes reflective ceilings, walls, and fans. Cooling is provided by ventilation and ceiling fans. Without this option many of the low income Puerto Rico residences will be building 'informally', which translates to outside the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This provides an alternative to "informal" housing which is built outside the code. Mainland style air tightness, windows, and even the HVAC systems are not appropriate to this housing. How do you access the costs for housing that is not built under the code now?

Staff Analysis: Please note that due to the requirements of the cdpACCESS system, where a new subsection is created and is populated with existing text, the existing text must be shown as removed from the existing section and shown as new in the new section. The 11 items in the new section R401.2.1.1 are the 11 items in the current code. They are simply relocated.

Proposal # 5640

CE54-19 Part II
Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Gutman, BCAP-IBTS, representing BCAP-IBTS (mgutman@bcapcodes.org); Harry Misuriello, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Add new text as follows:

C401.3 Thermal envelope certificate (Mandatory). A permanent thermal envelope certificate shall be completed by an approved party. Such certificate shall be posted on a wall in the space where the space conditioning equipment is located, a utility room or other approved location. If located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. A copy of the certificate shall also be included in the construction files for the project. The certificate shall include:

1. R-values of insulation installed in or on ceilings, roofs, walls, foundations and slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces;
2. U-factors and solar heat gain coefficients (SHGC) of fenestration;
3. Results from any building envelope air leakage testing performed on the building

Where there is more than one value for any component of the building envelope, the certificate shall indicate the area-weighted average value where available. If the area-weighted average is not available, the certificate shall list each value that applies to 10% or more of the total component area.

Reason: The purpose of this code change proposal is to add a permanent certificate to commercial buildings that will record basic information related to the building thermal envelope. This is similar to the requirement for residential buildings in Section R401.3, which has been in the IECC since at least the 2006 edition and has been successfully integrated into software programs such as REScheck. A significant percentage of commercial buildings will undergo system commissioning under Section C408, which will include documentation of mechanical and lighting systems. However, there is no similar requirement or documentation for the building’s thermal envelope components. We acknowledge that the commercial provisions of the IECC are intended to cover an extremely broad range of commercial buildings, so the certificate requirement has been simplified to cover only the basic elements of the thermal envelope.

The information contained in this certificate will be readily available at construction, but as the building ages and ownership is transferred, some of this critical information could be lost. As future owners or lessors undertake load calculations for HVAC sizing or other measures that require a working knowledge of the building’s thermal envelope characteristics, this information will be important. Recording the information in a permanent manner in an approved location at the building, as well as including documentation in the construction files for the project would not be overly burdensome but would provide valuable information to future building owners.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The information required to be included in the thermal envelope certificate will be readily available at construction and can be easily integrated into compliance software. This same information could be difficult to obtain several years down the road and recording it at construction will save future owners and lessors of a commercial building both time and money.
FENESTRATION. Products classified as either skylights or vertical fenestration.

Skylights Glass or other transparent or translucent glazing material installed at a slope of less than 60 degrees (1.05 rad) from horizontal, including unit skylights, tubular daylighting devices and glazing materials in solariums, sunrooms, roofs, greenhouses, and sloped walls.

Vertical fenestration Windows that are fixed or operable, opaque doors, glazed doors, glazed block and combination opaque and glazed doors composed of glass or other transparent or translucent glazing materials and installed at a slope of not less than 60 degrees (1.05 rad) from horizontal.

Revise as follows:

GREENHOUSE. A structure or a thermally isolated area of a building that maintains a specialized sunlit environment exclusively used for, and essential to, the cultivation, protection or maintenance of plants. Greenhouses are those that are erected for a period of 180 days or more.

Add new definition as follows:

INTERNAL CURTAIN SYSTEM. An internal curtain system consists of moveable panels of fabric or plastic film used to cover and uncover the space enclosed in a greenhouse on a daily basis.

Revise as follows:

C402.1.1 Low-energy buildings and greenhouses. The following low-energy buildings, or portions thereof separated from the remainder of the building by building thermal envelope assemblies complying with this section, shall be exempt from the building thermal envelope provisions of Section C402.

1. Those with a peak design rate of energy usage less than 3.4 Btu/h • ft² (10.7 W/m²) or 1.0 watt per square foot (10.7 W/m²) of floor area for space conditioning purposes.
2. Those that do not contain conditioned space.

Add new text as follows:

402.1.1.1 Greenhouses Greenhouse structures or areas that are mechanically heated or cooled and that comply with all of the following shall be exempt from the building envelope requirements of this code:

1. Exterior opaque envelope assemblies comply with Sections C402.2 and C402.4.5.

Exception: Low energy greenhouses that comply with Section C402.1.1.

2. Interior partition building thermal envelope assemblies that separate the greenhouse from conditioned space comply with Sections C402.2, C402.4.3 and C402.4.5.
3. Fenestration assemblies that comply with the thermal envelope requirements in Table C402.1.1.1. The U-factor for a roof shall be for the roof assembly or a roof that includes the...
assembly and an internal curtain system.

Exception: Unconditioned greenhouses.

**TABLE C402.1.1.1**

FENESTRATION THERMAL ENVELOPE MAXIMUM REQUIREMENTS

<table>
<thead>
<tr>
<th>Component</th>
<th>U-factor (BTU/h ft² °F)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skylight</td>
<td>0.5</td>
</tr>
<tr>
<td>Vertical fenestration</td>
<td>0.7</td>
</tr>
</tbody>
</table>

Reason: Greenhouses are currently exempt from the energy code through the low-energy building path even though they can use substantial amounts of energy. This proposal places commonplace envelope requirements on the structure when it is being mechanically heated or cooled. Low-energy use greenhouses structures are still exempt if they have a low energy usage per square foot in line with C402.1.1.

Cost Impact: The code change proposal will increase the cost of construction Costs of $1.27/sqft are based on a one-time installation cost of double IR poly-film at $0.10/sqft and a thermal curtain at $1.17/sqft. These costs are based on product offerings and utility rebate program findings. Total size of greenhouse assumed to be an average size single bay with dimensions of 35 feet wide, 100 feet long, 4-foot sidewalls and 14-foot total ceiling height.
CE57-19

IECC C402.1.1

Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C402.1.1 Low-energy buildings. The following low-energy buildings, or portions thereof separated from the remainder of the building by building thermal envelope assemblies complying with this section, shall be exempt from the building thermal envelope provisions of Section C402.

1. Those with a peak design rate of energy usage less than 3.4 Btu/h • ft² (10.7 W/m²) or 1.0 watt per square foot (10.7 W/m²) of floor area for space conditioning purposes.
2. Those that do not contain conditioned space.
4. Buildings with a floor area not greater than 1,100 square feet (102.2 square meters) in size and solely used to house electric distribution system equipment.

Reason: These buildings are used to house electric distribution equipment, not people. They are equipment sheds or equipment vaults. Any space conditioning installed is only meant to prevent damage to equipment due to extreme weather or storms. The amount of time that people work in these buildings (for maintenance or testing or repair) is minimal.

Based on feedback from EEI member companies, anywhere from 50% to 100% of utility vaults or enclosed switching stations or substations are not conditioned at all. For electric equipment buildings that are conditioned, the temperature settings are typically much higher in the summer (85 degrees F or higher) and much lower in the winter (60 degrees F or lower) than spaces that are meant for human comfort to be maintained on a regular basis.

Some of the electric equipment vaults being used by utilities are as large as 18 feet by 60 feet, or 1,080 square feet. The size limit of 1,100 square feet will ensure that the exemption is limited to these types of buildings.

Bibliography: Specifications for vaults from from different utilities can be found at the following web site links:

https://www.nationalgridus.com/media/pronet/constr_esb754759.pdf

Cost Impact: The code change proposal will decrease the cost of construction

This proposal is adding an exemption to the envelope requirements of Section Chapter 4, and as a result, will decrease the cost of construction for these low energy buildings.
Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C402.1.2 Equipment buildings. Buildings that comply with the following shall be exempt from the building thermal envelope provisions of this code:

1. Are separate buildings with floor area not more than 500-1,200 square feet (50-110 m²).
2. Are intended to house electronic electric equipment with installed equipment power totaling not less than 7 watts per square foot (75 W/m²) and not intended for human occupancy.
3. Have a heating system capacity not greater than (17,000 Btu/hr) (5 kW) and a heating thermostat setpoint that is restricted to not more than 50°F (10°C).
4. Have an average wall and roof U-factor less than 0.200 in Climate Zones 1 through 5 and less than 0.120 in Climate Zones 6 through 8.
5. Comply with the roof solar reflectance and thermal emittance provisions for Climate Zone 1.

Reason: There are many buildings that are used to house electric distribution equipment, not people. They are equipment sheds or equipment vaults. Any space conditioning installed is only meant to prevent damage to equipment due to extreme weather or storms. The amount of time that people work in these buildings (for maintenance or testing or repair) is minimal.

Based on feedback from EEI member companies, anywhere from 50% to 100% of utility vaults or enclosed switching stations or substations are not conditioned at all. They would qualify for this exception.

Some of the electric equipment vaults being used by utilities are as large as 18 feet by 60 feet, or 1,080 square feet. The size limit of 1,200 square feet will ensure that the exemption is limited to these types of buildings.

The other change, from "electronic" to "electric" is editorial and designed to prevent any confusion as to what types of equipment qualify for this section (e.g., a transformer vault has electric equipment that may be considered to be different from "electronic" equipment).

Bibliography: Specifications for vaults from from different utilities can be found at the following web site links:

https://www.nationalgridus.com/media/pronet/constr_esb754759.pdf

Cost Impact: The code change proposal will decrease the cost of construction
This proposal reduces the envelope requirements for these types of equipment buildings in Chapter 4, and as a result, will decrease the cost of construction for these low energy buildings.

Proposal # 5151
2018 International Energy Conservation Code

Add new text as follows:

C402.1.3 Low occupancy buildings Group S and Group U occupancy buildings shall be permitted to have a thermal performance in accordance with Sections C402.1.3.1 and C402.1.3.2.

Exception: Refrigerated warehouses.

C402.1.3.1 R-value-based method Opaque thermal envelope insulation components shall be not less than 65% of the values specified in Table C402.1.3 for commercial buildings.

C402.1.3.2 U-factor-based method Opaque thermal envelope assemblies shall be not greater than 150% of the values specified in Table C402.1.4 for commercial buildings.

Reason: This Code Change Proposal recognizes that building energy use is dependent upon more than whether a building is conditioned or non-conditioned-the use of the building has a greater impact. ASHRAE 90.1 recognizes that higher insulation levels are not always cost-justified and has a category of reduced thermal insulation requirements for "semi-heated buildings."

This code change proposal simplifies the application of those provisions by identifying the building occupancies that have low occupancies (low ventilation requirements) and often have high thermal masses of contents, resulting in low energy use for space conditioning. The R-values and U-factors are aligned closely with the insulation values in the 2006 edition of the IECC.

Cost Impact: The code change proposal will decrease the cost of construction

This code change proposal will reduce the cost of construction for many Group S and U occupancies.
CE60-19 Part I

PART I — IECC: C402.1.3

PART II — IECC: R202 (IRC N1101.6), R402.1.3 (IRC N1102.1.3)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association (jwoestman@kellencompany.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C402.1.3 Insulation component R-value-based method. Building thermal envelope opaque assemblies shall comply with the requirements of Sections C402.2 and C402.4 based on the climate zone specified in Chapter 3. For opaque portions of the building thermal envelope intended to comply on an insulation component R-value basis, the R-values for cavity insulation and continuous insulation shall be not less than that specified in Table C402.1.3. Where cavity insulation is installed in multiple layers, the cavity insulation R-values shall be summed to determine compliance with the cavity insulation R-value requirements. Where continuous insulation is installed in multiple layers, the continuous insulation R-values shall be summed to determine compliance with the continuous insulation R-value requirements. Cavity insulation R-values shall not be used to determine compliance with the continuous insulation R-value requirements in Table C402.1.3. Commercial buildings or portions of commercial buildings enclosing Group R occupancies shall use the R-values from the “Group R” column of Table C402.1.3. Commercial buildings or portions of commercial buildings enclosing occupancies other than Group R shall use the R-values from the “All other” column of Table C402.1.3.

Proposal # 5250
CE60-19 Part II

IECC: R202 (IRC N1101.6), R402.1.3 (IRC N1102.1.3)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association (jwoestman@kellencompany.com)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)

GENERAL DEFINITIONS

Add new definition as follows:

CAVITY INSULATION. Insulating material located between framing members.

Revise as follows:

R402.1.3 (IRC N1102.1.3) R-value computation. Insulation material used in layers, such as framing cavity insulation or continuous insulation. Cavity insulation alone shall be used to determine compliance with the cavity insulation R-value requirements in Table R402.1.2. Where cavity insulation is installed in multiple layers, the R-values of the cavity insulation layers shall be summed to determine compliance with the cavity insulation R-value requirements. The manufacturer’s settled R-value shall be used for blown-in insulation. Continuous insulation alone shall be used to determine compliance with the continuous insulation R-value requirements in Table R402.1.2. Where continuous insulation is installed in multiple layers, the R-values of the continuous insulation layers shall be summed to determine compliance with the continuous insulation R-value requirements. Computed R-values shall not include an R-value for other building materials or air films. Where insulated siding is used for the purpose of complying with the continuous insulation requirements of Table R402.1.2, the manufacturer’s labeled R-value for the insulated siding shall be reduced by R-0.6.

Reason: This proposal coordinates with proposed revisions to the IECC-C regarding appropriate consideration of multiple layers of insulation within a given insulation component and also clarifies that different insulation components (e.g., cavity insulation & continuous insulation) R-values cannot be summed because the mathematical result will not result in equivalent thermal performance due to cavity insulation components being interrupted by framing and continuous insulation not interrupted by framing.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. As this proposal is consistent with the intent of the code, there should be no affects on the cost of construction.

Proposal # 5248

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Assembly descriptions can be found in ANSI/ASHRAE/IESNA Appendix A.
b. Where using R-value compliance method, a thermal spacer block shall be provided, otherwise use the U-factor compliance method in Table C402.1.4-C402.1.4.
c. R-5.7ci is allowed to be substituted with concrete block walls complying with ASTM C90, ungrouted or partially grouted at 32 inches or less on center vertically and 48 inches or less on center horizontally, with ungrouted cores filled with materials having a maximum thermal conductivity of 0.44 Btu-in/h·f°F.
d. Where heated slabs are below grade, below-grade walls shall comply with the exterior insulation requirements for heated slabs.
e. “Mass floors” shall be in accordance with Section C402.2.3.
f. Steel floor joist systems shall be insulated to R-38.
g. “Mass walls” shall be in accordance with Section C402.2.2.
h. The first value is for perimeter insulation and the second value is for slab insulation. Perimeter insulation is not required to extend below the bottom of the slab.
i. Not applicable to garage doors. See Table C402.1.4-C402.1.4.

**Opaque doors**
For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly $U$-factors, $C$-factors, and $F$-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

b. Where $U$-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The $R$-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the $U$-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These $C$, $F$- and $U$-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to reduce energy costs for commercial building owners and improve long-term energy efficiency by adopting the more efficient and cost-effective opaque envelope requirements from ASHRAE Standard 90.1-2016 or the IECC for roofs. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

The commercial opaque envelope requirements of the IECC have not been comprehensively improved since the 2012 edition, even though ASHRAE has continued to make cost-effective improvements during that same period. This proposal leverages ASHRAE’s thorough energy savings and cost-effectiveness analyses to make improvements to the opaque envelope table where ASHRAE improves upon the IECC requirement, but without rolling back the IECC requirements where they meet or exceed the ASHRAE requirement.

We applied a consistent set of actions to each of the values in this table:

- Where ASHRAE Standard 90.1-2016 has a more efficient $U$-factor for an assembly, we propose adopting the ASHRAE $U$-factor.
- Where an improved $U$-factor is adopted, we incorporate an equivalent $R$-value based on Normative Appendix A of ASHRAE Standard 90.1-2016.

The resulting table provides moderate improvements in energy efficiency based on an established model energy code and corrects inconsistencies and errors in the current IECC prescriptive tables.

**Cost Impact:** The code change proposal will increase the cost of construction.
The improved U-factors and R-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each U-factor selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product.

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Assembly descriptions can be found in ANSI/ASHRAE/IESNA Appendix A.
b. Where using R-value compliance method, a thermal spacer block shall be provided, otherwise use the U-factor compliance method in Table C402.1.4.
c. R-5.7ci is allowed to be substituted with concrete block walls complying with ASTM C90, ungrouted or partially grouted at 32 inches or less on center vertically and 48 inches or less on center horizontally, with ungrouted cores filled with materials having a maximum thermal
conductivity of 0.44 Btu-in/h-ft\(^2\) °F.

d. Where heated slabs are below grade, below-grade walls shall comply with the exterior insulation requirements for heated slabs.
e. “Mass floors” shall be in accordance with Section C402.2.3.
f. Steel floor joist systems shall be insulated to R-38.
g. “Mass walls” shall be in accordance with Section C402.2.2 and C402.2.2.1.
h. The first value is for perimeter insulation and the second value is for slab insulation. Perimeter insulation is not required to extend below the bottom of the slab.
i. Not applicable to garage doors. See Table C402.1.4.

For SI: 1 pound per square foot = 4.88 kg/m\(^2\), 1 pound per cubic foot = 16 kg/m\(^3\).

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

#### a.
Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

#### b.
Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

#### c.
Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

#### d. “Mass floors” shall be in accordance with Section C402.2.3.

#### e. These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

#### f. The first value is for perimeter insulation and the second value is for full slab insulation.

#### g. “Mass walls” shall be in accordance with Section C402.2.2 and C402.2.2.1.

### C402.2.2 Above-grade walls.
The minimum thermal resistance (R-value) of materials installed in the wall cavity between framing members and continuously on the walls shall be as specified in Table C402.1.3, based on framing type and construction materials used in the wall assembly. The R-value of integral insulation
installed in concrete masonry units shall not be used in determining compliance with Table C402.1.3 except as otherwise noted in the table. In determining compliance with Table C402.1.4, the use of the \( U \)-factor of concrete masonry units with integral insulation shall be permitted.

"Mass walls" where used as a component in the thermal envelope of a building shall comply with one of the following:

1. Weigh not less than 35 pounds per square foot (171 kg/m\(^2\)) of wall surface area.
2. Weigh not less than 25 pounds per square foot (122 kg/m\(^2\)) of wall surface area where the material weight is not more than 120 pcf (1900 kg/m\(^3\)).
3. Have a heat capacity exceeding 7 Btu/ft\(^2\) • °F (144 kJ/m\(^2\) • K).
4. Have a heat capacity exceeding 5 Btu/ft\(^2\) • °F (103 kJ/m\(^2\) • K), where the material weight is not more than 120 pcf (1900 kg/m\(^3\)).

Add new text as follows:

C402.2.2.1 Mass walls. "Mass walls" where used as a component in the thermal envelope of a building shall comply with one of the following:

1. Weigh not less than 35 pounds per square foot (171 kg/m\(^2\)) of wall surface area.
2. Weigh not less than 25 pounds per square foot (122 kg/m\(^2\)) of wall surface area where the material weight is not more than 120 pcf (1900 kg/m\(^3\)).
3. Have a heat capacity exceeding 7 Btu/ft\(^2\) • °F (144 kJ/m\(^2\) • K).
4. Have a heat capacity exceeding 5 Btu/ft\(^2\) • °F (103 kJ/m\(^2\) • K), where the material weight is not more than 120 pcf (1900 kg/m\(^3\)).

Wall elements to the exterior of a vented air space shall be excluded when evaluating the mass wall thermal envelope criteria of this section.
CE62-19 Part II

IECC: R402.2.5 (IRC N1102.2.5)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association
(jwoestman@kellencompany.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.5 (IRC N1102.2.5) Mass walls. Mass walls where used as a component of the building thermal envelope shall be one of the following:

1. Above-ground walls of concrete block, concrete, insulated concrete form, masonry cavity, brick but not brick veneer, adobe, compressed earth block, rammed earth, solid timber or solid logs but not anchored brick veneer, anchored stone or masonry veneer.

2. Any wall having a heat capacity greater than or equal to 6 Btu/ft² °F (123 kJ/m² K) except components to the exterior of a vented air space shall be excluded from the heat capacity determination.

Reason: In Item 1, anchored brick veneer, anchored stone, and anchored masonry veneer are required by IRC Section R703.8 and Table R703.8.4(1) to be installed with an airspace of between 1" and 4 ½". The components of a wall to the exterior of a non-sealed (vented) air space required to provide drainage are disconnected thermally from the rest of the thermal envelope of the structure. Accordingly, components of walls to the exterior of a vented air space should not be considered a component of the building thermal envelope. This situation was recognized in Item 1 with the original text of “but not brick veneer”. This proposal, for clarity, moves “but not brick veneer” to the end of the sentence and includes anchored stone and masonry veneer which performs thermally similar to brick veneer. Also, “anchored” is inserted in two locations to appropriately differentiate anchored veneer with the required airspace from adhered masonry veneer addressed in IRC Section R703.12.

Proposed revisions in Item 2 exclude components of the wall to the exterior of a vented air space from the heat capacity calculation because these components are disconnected thermally from the rest of the thermal envelope of the structure.

This proposal is consistent with requirements for mass walls in IECC-C Section C402.2.2 which is similarly clarified in a separate proposal. These changes are needed to clearly recognize that the “mass” of a mass wall must be an integral part of the wall (not thermally disconnected by a vented air space) as was the basis for determining thermal inertia (thermal mass) effects and associated R-value requirements for mass wall assemblies.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The revisions in Item 1 should not raise the cost of construction because the proposed revisions are consistent with the intent of Item 1. In Item 2, if exterior wall components to the exterior of a vented air space have been considered mass walls in conflict with the intent of Item 1, there could be a cost increase.
### 2018 International Energy Conservation Code

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

**ci** = Continuous insulation, **NR** = No Requirement, **LS** = Liner System.

**a.** Where assembly **U**-factors, **C**-factors, and **F**-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.

**b.** Where **U**-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The **R**-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

**c.** Where heated slabs are below grade, below-grade walls shall comply with the **U**-factor requirements for above-grade mass walls.

**d.** “Mass floors” shall be in accordance with Section C402.2.3.

**e.** These **C**-, **F**-, and **U**-factors are based on assemblies that are not required to contain insulation.

**f.** The first value is for perimeter insulation and the second value is for full slab insulation.

**g.** “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to reduce energy costs for commercial building owners and improve long-term energy efficiency by adopting the more efficient and cost-effective opaque envelope requirements from either ASHRAE Standard 90.1-2016 or the IECC for above-grade walls. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

The commercial opaque envelope requirements of the IECC have not been comprehensively improved since the 2012 edition, even though ASHRAE has continued to make cost-effective improvements during that same period. This proposal leverages ASHRAE’s thorough energy savings and cost-effectiveness analyses to make improvements to the opaque envelope table where ASHRAE improves upon the IECC requirement, but without rolling back the IECC requirements where they meet or exceed the ASHRAE requirement.
We applied a consistent set of actions to each of the values in this table:

- Where we discovered clear errors or inconsistencies between the U-factor and R-value table, we corrected them.
- Where ASHRAE Standard 90.1-2016 has a more efficient U-factor for an assembly, we propose adopting the ASHRAE U-factor.
- Where an improved U-factor is adopted, we incorporate an equivalent R-value based on Normative Appendix A of ASHRAE Standard 90.1-2016.

The resulting table provides moderate improvements in energy efficiency based on an established model energy code and corrects inconsistencies and errors in the current IECC prescriptive tables.

**Cost Impact:** The code change proposal will increase the cost of construction. The improved U-factors and R-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each U-factor selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product.

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.

b. Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.
g. “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to reduce energy costs for commercial building owners and improve long-term energy efficiency by adopting the more efficient and cost-effective opaque envelope requirements from ASHRAE Standard 90.1-2016 or the IECC for below-grade walls. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

The commercial opaque envelope requirements of the IECC have not been comprehensively improved since the 2012 edition, even though ASHRAE has continued to make cost-effective improvements during that same period. This proposal leverages ASHRAE’s thorough energy savings and cost-effectiveness analyses to make improvements to the opaque envelope table where ASHRAE improves upon the IECC requirement, but without rolling back the IECC requirements where they meet or exceed the ASHRAE requirement.

We applied a consistent set of actions to each of the values in this table:

- Where ASHRAE Standard 90.1-2016 has a more efficient U-factor for an assembly, we propose adopting the ASHRAE U-factor.
- Where an improved U-factor is adopted, we incorporate an equivalent R-value based on Normative Appendix A of ASHRAE Standard 90.1-2016.

The resulting table provides moderate improvements in energy efficiency based on an established model energy code and corrects inconsistencies and errors in the current IECC prescriptive tables.

**Cost Impact:** The code change proposal will increase the cost of construction.

The improved U-factors and R-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each U-factor selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product.

</tbody>
</table>

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

b. Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to improve consistency by applying an R-value for joist/framing floors in climate zone 1 in Table C402.1.3 that matches the corresponding U-factor in Table C402.1.4. The U-factor for joist/framing floors in Table C402.1.4 is consistent with a wood-framed floor insulated to R-13, despite the “NR” notation and footnote “e,” which indicate no insulation in the assembly. Because other U-factors and R-values for joist/framing floors in Table C402.1.3 are based on wood-framed assemblies, we applied the equivalent R-value requirement for a U-factor of 0.066, which is R-13. This will improve energy efficiency as compared to the current Table C402.1.3, but it will bring consistency to the two prescriptive tables and simplify enforcement.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

We believe the R-value equivalent in Table C402.1.4 is an error in the IECC and should be made consistent with the U-factor Table.

Proposal # 4645
## 2018 International Energy Conservation Code

Revise as follows:

### TABLE C402.1.3

**OPAQUE THERMAL ENVELOPE INSULATION COMPONENT MINIMUM REQUIREMENTS, R-VALUE METHOD**

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>CLIMATE ZONE</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4 EXCEPT MARINE</th>
<th>5 AND MARINE 4</th>
<th>6</th>
<th>7</th>
</tr>

<td>NR</td>
<td>R-6.3ci</td>
<td>R-8.3ci</td>
<td>R-10ci</td>
<td>R-10ci</td>
<td>R-10ci</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 4.88 kg/m\(^2\), 1 pound per cubic foot = 16 kg/m\(^3\).

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

- **a.** Assembly descriptions can be found in ANSI/ASHRAE/IESNA Appendix A.
- **b.** Where using R-value compliance method, a thermal spacer block shall be provided, otherwise use the U-factor compliance method in Table C402.1.4.
- **c.** R-5.7ci is allowed to be substituted with concrete block walls complying with ASTM C90, ungrouted or partially grouted at 32 inches or less on center vertically and 48 inches or less on center horizontally, with ungrouted cores filled with materials having a maximum thermal conductivity of 0.44 Btu-in/h-f°F.
- **d.** Where heated slabs are below grade, below-grade walls shall comply with the exterior insulation requirements for heated slabs.
- **e.** “Mass floors” shall be in accordance with Section C402.2.3.
- **f.** Steel floor joist systems shall be insulated to R-38.
- **g.** “Mass walls” shall be in accordance with Section C402.2.2.
- **h.** The first value is for perimeter insulation and the second value is for slab insulation. Perimeter insulation is not required to extend below the bottom of the slab.
- **i.** Not applicable to garage doors. See Table C402.1.4.

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.

b. Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.

Reason: The purpose of this code change proposal is to reduce energy costs for commercial building owners and improve long-term energy efficiency by adopting the more efficient and cost-effective opaque envelope requirements from ASHRAE Standard 90.1-2016 or the IECC for floors. Because all framed floor systems will be required to be insulated to R-38, there is no longer a need for footnote “f” in Table C402.1.3. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.” The commercial opaque envelope requirements of the IECC have not been comprehensively improved since
the 2012 edition, even though ASHRAE has continued to make cost effective improvements during that same period. This proposal leverages ASHRAE’s thorough energy savings and cost-effectiveness analyses to make improvements to the opaque envelope table where ASHRAE improves upon the IECC requirement, but without rolling back the IECC requirements where they meet or exceed the ASHRAE requirement.

We applied a consistent set of actions to each of the values in this table:

- Where we discovered clear errors or inconsistencies between the U-factor and R-value table, we corrected them.
- Where ASHRAE Standard 90.1-2016 has a more efficient U-factor for an assembly, we propose adopting the ASHRAE U-factor.
- Where an improved U-factor is adopted, we incorporate an equivalent R-value based on Normative Appendix A of ASHRAE Standard 90.1-2016.

The resulting table provides moderate improvements in energy efficiency based on an established model energy code and corrects inconsistencies and errors in the current IECC prescriptive tables.

**Cost Impact:** The code change proposal will increase the cost of construction
The improved U-factors and R-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each U-factor selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product.

</table>

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.

- **a.** Where assembly *U*-factors, *C*-factors, and *F*-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

- **b.** Where *U*-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The *R*-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

- **c.** Where heated slabs are below grade, below-grade walls shall comply with the *U*-factor requirements for above-grade mass walls.

- **d.** “Mass floors” shall be in accordance with Section C402.2.3.

- **e.** These *C*-, *F*- and *U*-factors are based on assemblies that are not required to contain insulation.

- **f.** The first value is for perimeter insulation and the second value is for full under-slab insulation.

- **g.** “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** To be clear, it was the intent of the proponent to be specific to “full, under-slab” installations in these instances; Table C402.1.3 and Table C402.1.4.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification. No change to stringency is proposed.

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.
Where assembly $U$-factors, $C$-factors, and $F$-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

Where $U$-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The $R$-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

Where heated slabs are below grade, below-grade walls shall comply with the $U$-factor requirements for above-grade mass walls.

“Mass floors” shall be in accordance with Section C402.2.3.

These $C$, $F$- and $U$-factors are based on assemblies that are not required to contain insulation.

The first value is for perimeter insulation and the second value is for full slab insulation.

“Mass walls” shall be in accordance with Section C402.2.2.

Reason: The purpose of this code change proposal is to reduce energy costs for commercial building owners and improve long-term energy efficiency by adopting the more efficient and cost-effective opaque envelope requirements from ASHRAE Standard 90.1-2016 or the IECC for slab-on-grade floors in climate zones 3-6. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

The commercial opaque envelope requirements of the IECC have not been comprehensively improved since the 2012 edition, even though ASHRAE has continued to make cost-effective improvements during that same period. This proposal leverages ASHRAE’s thorough energy savings and cost-effectiveness analyses to make improvements to the opaque envelope table where ASHRAE improves upon the IECC requirement, but without rolling back the IECC requirements where they meet or exceed the ASHRAE requirement.

We applied a consistent set of actions to each of the values in this table:

- Where ASHRAE Standard 90.1-2016 has a more efficient $U$-factor for an assembly, we propose adopting the ASHRAE $U$-factor.
- Where an improved $U$-factor is adopted, we incorporate an equivalent $R$-value based on Normative Appendix A of ASHRAE Standard 90.1-2016.

The resulting table provides moderate improvements in energy efficiency based on an established model energy code and corrects inconsistencies and errors in the current IECC prescriptive tables.

Cost Impact: The code change proposal will increase the cost of construction. The improved $F$-factors and $R$-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each $U$-factor selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product.

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

ci = Continuous insulation, NR = No Requirement, LS = Liner System.
a. Where assembly $U$-factors, $C$-factors, and $F$-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.

b. Where $U$-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The $R$-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the $U$-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These $C$, $F$- and $U$-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to reduce building energy costs and improve long-term energy efficiency by adopting ASHRAE’s more efficient and cost-effective requirements for unheated slab insulation in climate zones 7-8. The current IECC F-factors for unheated slabs in these climate zones do not correspond with the R-value requirements in Table C402.1.3, nor do they correspond with F-factor data for common slab-on-grade floor assemblies per Normative Appendix A of ASHRAE Standard 90.1-2016. We believe the F-factors in the IECC are in error, and we propose adopting both ASHRAE's R-values and F-factors for these climate zones. The result will be improved efficiency and consistency across the IECC’s prescriptive tables. The building envelope typically remains the same for many years after construction and it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

**Cost Impact:** The code change proposal will increase the cost of construction

The improved F-factors and R-values in Tables C402.1.3 and C402.1.4 will typically require the addition of more insulation or other efficiency improvements in the IECC’s performance-based compliance paths. However, each component value selected by ASHRAE for Standard 90.1 has gone through a rigorous energy-savings and cost-effectiveness analysis and consensus vetting from affected interests, so even in cases where construction costs are increased, the improvements will be achievable and cost-effective over the useful life of the product. This proposal will also correct an error in the IECC Table C402.1.4 and bring consistency between the two prescriptive tables, simplifying compliance and enforcement.

</table>

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.
ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly $U$-factors, $C$-factors, and $F$-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

b. Where $U$-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The $R$-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the $U$-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These $C$, $F$, and $U$-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.

h. Swinging door $U$-factors shall be determined in accordance with NFRC-100.

C402.4.5 Doors. Opaque swinging doors shall be considered as part of the gross area of above-grade walls that are part of the building thermal envelope. Opaque doors shall comply with Section C402.4.5.1 or Section C402.5.2.

Add new text as follows:

**C402.5.1 Opaque swinging doors** Opaque nonswinging doors shall comply with Table C402.1.4.

**C402.4.5.2 Nonswinging Doors.** Opaque nonswinging doors that are horizontally hinged sectional doors with a single row of fenestration shall have an assembly $U$-factor less than or equal to 0.440 in Climate Zones 0 through 6 and less than or equal to 0.360 in Climate Zones 7 and 8, provided the fenestration area is at least 14 percent and not more than 25 percent of the total door area. Exception: Other doors shall comply with the provisions of Section C402.4.3 for vertical fenestration.

**Reason:** Based on cost data gathered from industry partners and thermal performance from ASHRAE research project 1236 the optimal $U$-factor for these doors was determined. The performance of doors is more accurately reflected using $U$-factors. Additionally, the industry is moving towards assembly $U$-factors rather than $R$-values for these products. In the event that other proposals introduce Climate Zone 0 the current values for Climate Zone 1 should be used for Climate Zone 0 as well.

**Cost Impact:** The code change proposal will increase the cost of construction Using national energy costs of $1.22/therm for natural gas, $.0939 for electricity, and a 40 year life time, as expressed in the formula LLC = (U*SRh*H*HDD*Pn) + (U*SRC*{(Ccoefficient * CDD)+Ccoefficient2}*Pc), the proposed door criteria have the lowest Life Cycle Cost as indicated in the table below. For an explanation of the formula above, see Development of Economic Scalar Ratios for ASHRAE Standard 90.1.

2018 International Energy Conservation Code

C402.1.4 Assembly $U$-factor, $C$-factor or $F$-factor-based method. Building thermal envelope opaque assemblies shall meet the requirements of Sections C402.2 and C402.4 based on the climate zone specified in Chapter 3. Building thermal envelope opaque assemblies intended to comply on an assembly $U$, $C$- or $F$-factor basis shall have a $U$, $C$- or $F$-factor not greater than that specified in Table C402.1.4. Commercial buildings or portions of commercial buildings enclosing Group R occupancies shall use the $U$, $C$- or $F$-factor from the “Group R” column of Table C402.1.4. Commercial buildings or portions of commercial buildings enclosing occupancies other than Group R shall use the $U$, $C$- or $F$-factor from the “All other” column of Table C402.1.4.

Add new text as follows:

C402.1.4.1 Roof/Ceiling Assembly. The maximum, roof/ceiling assembly $U$-factor shall not exceed that specified in Table C402.1.4 based on construction materials used in the roof/ceiling assembly.

C402.1.4.1.1 Tapered, above-deck insulation based on thickness. Where used as a component of a maximum roof/ceiling assembly $U$-factor calculation, the sloped roof insulation R-value contribution to that calculation shall use either the arithmetic average thickness or the volumetric average thickness in inches (mm) along with the material R-value-per-inch (per-mm) solely for $U$-factor compliance as prescribed in Section C402.1.4.

C402.1.4.1.2 Suspended ceilings. Insulation installed on suspended ceilings having removable ceiling tiles shall not be considered part of the minimum thermal resistance (R-value) of roof insulation or assembly $U$-factor of the roof/ceiling construction.

C402.1.4.1.3 Joints staggered. Continuous insulation board shall be installed in not less than two layers and the edge joints between each layer of insulation shall be staggered, except where insulation tapers to the roof deck at a gutter edge, roof drain or scupper.

Revise as follows:

C402.2.1 Roof assembly. The minimum thermal resistance (R-value) of the insulating material installed either between the roof framing or continuously on the roof assembly shall be as specified in Table C402.1.3, based on construction materials used in the roof assembly. Insulation installed on a suspended ceiling having removable ceiling tiles shall not be considered as part of the minimum thermal resistance of the roof insulation. Continuous insulation board shall be installed in not less than 2 layers and the edge joints between each layer of insulation shall be staggered.

Exceptions:

1. Continuously insulated roof assemblies where the thickness of insulation varies 1 inch (25 mm) or less and where the area-weighted $U$-factor is equivalent to the same assembly with the R-value specified in Table C402.1.3.

2. Where tapered insulation is used with insulation entirely above deck, the R-value where the insulation thickness varies 1 inch (25 mm) or less from the minimum thickness of tapered
insulation shall comply with the R-value specified in Table C402.1.3.

3. Two layers of insulation are not required where insulation tapers to the roof deck, such as at roof-drains.

Add new text as follows:

C402.2.1.1 Tapered, above-deck insulation based on thickness. Where used as a component of a maximum roof/ceiling assembly R-value calculation, the sloped roof insulation R-value contribution to that calculation shall use either the arithmetic average thickness or the volumetric average thickness in inches (mm) along with the material R-value-per-inch (per-mm) solely for R-value compliance as prescribed in Section C402.1.4.

C402.2.1.2 Minimum thickness, lowest point. The minimum thickness of tapered, above-deck roof insulation at its lowest point, gutter edge, roof drain or scupper, shall be no less than 1 inch (25 mm).

C402.2.1.3 Suspended ceilings. Insulation installed on suspended ceilings having removable ceiling tiles shall not be considered part of the minimum thermal resistance (R-value) of roof insulation or assembly U-factor of the roof/ceiling construction.

C402.2.1.4 Joints staggered. Continuous insulation board shall be installed in not less than two layers and the edge joints between each layer of insulation shall be staggered, except where insulation tapers to the roof deck at a gutter edge, roof drain or scupper.

Revise as follows:

C402.2.1.4 C402.2.1.5 Skylight curbs. Skylight curbs shall be insulated to the level of roofs with insulation entirely above the deck or R-5, whichever is less.

   Exception: Unit skylight curbs included as a component of a skylight listed and labeled in accordance with NFRC 100 shall not be required to be insulated.

Reason: The primary objective of this proposal is to repair and preserve the intent in original change EC31-03/04 (AM PC) by New Buildings Institute which correctly added a “first-ever” use of an R-value equivalent, area-weighted average U-factor option in lieu of an “R-value Only” compliance option. This change also addresses confusing code syntax suggested by NRCA’s own follow-on proposal several cycles later CE115-13 (AS) to provide guidance as to how code users use the first three rows of Table C402.1.4.

The clear intent of the “charging” paragraph to Section C402.2 is to limit the following sub-sections (C402.2.1 Roofs, C402.2.2 Walls, C402.2.3 Floors, etc.) solely to the R-value compliance method by way of Table C402.1.3. Accordingly, this proposal is limited solely to correctly relocating the appropriate U-factor alternative as a New! subsection to C402.1.4 where it belongs; for roof/ceiling installations only. With this proposal, NRCA is leaving it to others to clean the remaining instances throughout C402.2 where R-value compliance and U-factor compliance are mixed and matched.

To begin, NBI’s EC31-03/04 correctly proposed a “first-ever” option to allow the use of R-value equivalent, area-weighted average U-factors in lieu of “R-values only.” At the time the 2003 IECC offered an “R-values only” compliance path. Note, an “Equivalent U-factor” compliance path did not first appear until the 2009 IECC Edition. So then, while EC31-03/04 was innovative in allowing the accepted engineering practice of an area-weighted calculation, it did not provide the level of specificity on which to base or how to perform the calculation. Nonetheless, it should be recognized that EC31-03/04 clearly passed as an endorsement that approved, area-weighted average U-factor calculations are to be recognized in the IECC. Notwithstanding such endorsement, EC31-03/04 left many in the industry without a code-enforceable solution.
802.2.4 Roof assembly. The minimum thermal resistance ($R$-value) of the insulating material installed either between the roof framing or continuously on the roof assembly shall be as specified in Table 802.2.1(1), based on construction materials used in the roof assembly.

**Exception:** Continuously insulated roof assemblies where the thickness of insulation varies 1 inch (25.4 mm) or less and where the area weighted $U$-factor is equivalent to the same assembly with the $R$-value specified in Table 802.2.1(1).

Sometime later, and well after the 2009 IECC was improved to allow an “Equivalent $U$-factor” methodology, CE115-13 was proposed by the NRCA. In the reason to CE115-13, the NRCA admitted its members had become confused with regard to NBI’s original intent for the lone exception to Section 802.2.4; but also, that it was the intent of the NRCA to “clarify the use and application of slope-to-drain insulation in roofing projects.” Regrettably, the NRCA suggested solution (i.e., the coexistence of Section 402.2.1, Exceptions 1 and 2 as they read today) did not reflect the historical evidence and eventual evolution of the 2009 IECC thereon to recognize the accepted engineering practice of an area-weighted calculation.

The proposal preserves the independent expressions of 1) minimum thickness, 2) staggered joints, 3) back-loaded, suspended ceilings and 4) skylight curbs along with 5) tapered insulation system designs that are consistent with *The NRCA Roofing Manual for Membrane Roof Systems* written in code-enforceable language. *The NRCA Roofing Manual for Membrane Roof Systems-2019 Ed.*, is a continuation of a long-standing series of publications from the National Roofing Contractors Association (NRCA) intended to provide in-depth, expert and best industry practices concerning the design, materials and installation of quality membrane roof systems.

It is unnecessary to preserve the minimum “skylight curb” provision of C402.2.1.1 as the Assembly $U$-factor, $C$-factor or $F$-factor-based method provides the user with maximum flexibility toward achieving assembly $U$-factor, $C$-factor or $F$-factor-based compliance in accordance with Table C402.1.4 and accepted engineering practices.

For the utility of future users, the following excerpts and figures from *The NRCA Roofing Manual for Membrane Roof Systems-2015 Ed.*, could be used as explanatory commentary:

1. For one- and two-way, sloped roof insulation systems the arithmetic average thickness shall be calculated in accordance with Equation 4-W and as indicated in Figure 4-4. For more complex sloped configurations, the tapered layout shall be broken down into one- and two-way slope regions.

$$\text{Arithmetic average thickness} = \text{LP} + \left[ \frac{1}{2} \times \text{HP} - \text{LP} \right] \text{ (Equation 4-W)}$$

![Figure 4-4: Arithmetic average thickness](image-url)
2. For symmetrical square, four-way sloped roof insulation systems the volumetric average thickness shall be calculated in accordance with Equation 4-X or 4-Y, and as indicated in Equations 4-5 or 4-6, respectively.

Volumetric average thickness = \( LP + \left[ \frac{2}{3} \times (HP - LP) \right] \) (Equation 4-X)

![Volumetric average thickness](image)

Volumetric average thickness = \( \frac{\text{Volume of insulation}}{\text{Roof surface area}} \) (Equation 4-Y)

3. For all other sloped roof insulation systems, the volumetric average thickness shall be calculated in accordance with Equation 4-Z and as indicated in Figure 4-7.

![Symmetrical four-way slope](image)

Volumetric average thickness = \( \frac{\text{Volume of insulation} - \text{Volume anticipated waste}}{\text{Roof surface area}} \)
where:

LP = Lowest point, or insulation system minimum thickness.

HP = Highest point, or insulation system maximum thickness.

L = Length, one side of square roof surface area.

Volume of solid insulation = HP x L^2

Volume of empty space = 1/3 x L x (HP – LP)

Volume of insulation = (HP x L^2) - 1/3 x L x (HP – LP)

The proposal is product neutral and inclusive of all rigid board insulation types including, cellular glass, expanded and extruded polystyrene, faced and fiber-reinforced gypsum board, stone wool, perlite board, polyisocyanurate, high-density polyisocyanurate, wood fiber board and composite board.

**Bibliography:** NRCA Roofing Manual for Membrane Roof Systems - 2019 Ed., National Roofing Contractors Association, 10255 W. Higgins Road, suite 600, rosemont, IL 60018-5607.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
The code change proposal will not increase or decrease the cost of construction, as the provisions of C402.1.4, Assembly U-factor, C-factor or F-factor-based methodolog[ies], remain a design option addressing constructability issues in new construction and reroofing projects even without the change, and where a newly proposed or existing roof deck does not provide adequate slope for positive drainage.
2018 International Energy Conservation Code

Revise as follows:

C402.1.4 Assembly $U$-factor, $C$-factor or $F$-factor-based method. Building thermal envelope opaque assemblies shall meet the requirements of Sections C402.2 and C402.4 based on the climate zone specified in Chapter 3. Building thermal envelope opaque assemblies intended to comply on an assembly $U$-, $C$- or $F$-factor basis shall have a $U$-, $C$- or $F$-factor not greater than that specified in Table C402.1.4. Commercial buildings or portions of commercial buildings enclosing Group R occupancies shall use the $U$-, $C$- or $F$-factor from the “Group R” column of Table C402.1.4. Commercial buildings or portions of commercial buildings enclosing occupancies other than Group R shall use the $U$-, $C$- or $F$-factor from the “All other” column of Table C402.1.4

Add new text as follows:

C402.1.4.1 Tapered, above-deck insulation based on thickness. Continuously insulated roof assemblies where the thickness of insulation varies 1 inch (25 mm) or more and where the area-weighted $U$-factor is equivalent to the same assembly with the $U$-factor specified in Table C402.1.4.

C402.1.4.2 Suspended ceilings Insulation installed on suspended ceilings having removable ceiling tiles shall not be considered part of the minimum thermal resistance ($R$-value) of roof insulation or assembly $U$-factor of the roof/ceiling construction.

C402.1.4.3 Joints staggered Continuous insulation board shall be installed in not less than two (2) layers and the edge joints between each layer of insulation shall be staggered, except where insulation tapers to the roof deck at a gutter edge, roof drain or scupper.

Revise as follows:

C402.2.1 Roof assembly. The minimum thermal resistance ($R$-value) of the insulating material installed either between the roof framing or continuously on the roof assembly shall be as specified in Table C402.1.3, based on construction materials used in the roof assembly. Insulation installed on a suspended ceiling having removable ceiling tiles shall not be considered as part of the minimum thermal resistance of the roof insulation. Continuous insulation board shall be installed in not less than 2 layers and the edge joints between each layer of insulation shall be staggered.

Exceptions:

1. Continuously insulated roof assemblies where the thickness of insulation varies 1 inch (25 mm) or less and where the area-weighted $U$-factor is equivalent to the same assembly with the $R$-value specified in Table C402.1.3:

2. Where tapered insulation is used with insulation entirely above deck, the $R$-value where the insulation thickness varies 1 inch (25 mm) or less more from the minimum thickness of tapered insulation shall comply with the $R$-value specified in Table C402.1.3.

3. Two layers of insulation are not required where insulation tapers to the roof deck, such as at roof drains.
**Reason:** The goal of this proposal is to repair and preserve the intent in original proposal EC31-03/04 (AM PC) by New Buildings Institute which correctly added a “first-ever” use of an R-value equivalent, area-weighted average U-factor option in lieu of an “R-value only” compliance option.

The clear intent in the “charging” paragraph of Section C402.2 is to limit its following sub-sections (C402.2.1 Roofs, C402.2.2 Walls, C402.2.3 Floors, etc.) solely to R-value compliance by way of Table C402.1.3. Accordingly, this proposal is limited solely to correctly distinctly separating and relocating the appropriate U-factor alternative as a subsection to C402.1.4 where it belongs. NRCA proposed this for roof/ceiling installations only as roofing and related professions is our charge. We leave it to others, then, to clean the remaining instances throughout C402.2 where R-value compliance and U-factor compliance are mixed and co-matched inappropriately within C402.2.

The proposal preserves the independent expressions of 1) minimum thickness, 2) staggered joints and 3) back-loaded, suspended ceilings from C402.2.1, as appropriate.

It is unnecessary to preserve the minimum “skylight curb” provision of C402.2.1.1 as the Assembly U-factor, C-factor or F-factor-based method provides the user with maximum flexibility toward achieving assembly U-factor, C-factor or F-factor-based compliance in roof/ceiling construction in accordance with Table C402.1.4, accepted engineering and architectural practice.

The proposal is product neutral and inclusive of all rigid board insulation types including, cellular glass, expanded and extruded polystyrene, faced and fiber-reinforced gypsum board, stone wool, perlite board, polyisocyanurate, high-density polyisocyanurate, wood fiber board and composite board.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The code change proposal will not increase or decrease the cost of construction, as the provisions of C402.1.4, Assembly U-factor, C-factor or F-factor-based methodolog[ies], remain a design option addressing constructability issues in new construction and reroofing projects even without the change, and where a newly proposed or existing roof deck does not provide adequate slope for positive drainage.

Proposal # 5308

CE72-19
2018 International Energy Conservation Code

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

CI = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.

b. Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.

e. These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

f. The first value is for perimeter insulation and the second value is for full slab insulation.

g. “Mass walls” shall be in accordance with Section C402.2.2.
**Reason:** The purpose of this code change proposal is to correct the U-factor for roof insulation for All Other metal buildings in climate zone 1. Even though the R-values in Table C402.1.3 for both Group R and All Other metal buildings in climate zone 1 are R-19+R 11 LS, the U-factor table applies a higher U-factor for All Other metal buildings. This proposal adopts the U-factor from Group R for both building types in climate zone 1, since it is closest to the R-19+R-11 LS U-factor equivalent in Table A2.3.3 in ASHRAE Standard 90.1 Normative Appendix A. The building envelope typically remains the same for many years after construction and it is particularly important to “get it right” at the time of construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The current metal building roof U-factor for All Other buildings is an error and is inconsistent with the R-value equivalent in Table C402.1.3.

Proposal # 4207

</tbody>
</table>

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

(ci = Continuous insulation, NR = No Requirement, LS = Liner System.

a. Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

b. Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

c. Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

d. “Mass floors” shall be in accordance with Section C402.2.3.
These $C$, $F$, and $U$-factors are based on assemblies that are not required to contain insulation.

The first value is for perimeter insulation and the second value is for full slab insulation.

“Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The purpose of this code change proposal is to correct an apparent error in the U-factor for above-grade mass walls in climate zone 8. Table C402.1.3 of the 2018 IECC requires R-25 continuous insulation for both Group R and All Other building types, but the U-factor is significantly higher than what would be considered equivalent in Normative Appendix A of ASHRAE Standard 90.1-2016. Revising the U-factor to 0.037 for climate zone 8 will apply a consistent set of requirements across the R-value and U-factor tables. The building envelope typically remains the same for many years after construction and it is particularly important to “get it right” at the time of construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The current above grade mass wall U-factor for climate zone 8 is an error and is inconsistent with the R-value equivalent in Table C402.1.3.
## 2018 International Energy Conservation Code

</tbody>
</table>

For SI: 1 pound per square foot = 4.88 kg/m\(^2\), 1 pound per cubic foot = 16 kg/m\(^3\).

\( ci \) = Continuous insulation, NR = No Requirement, LS = Liner System.

---

**Notes:**
- \(^a\) Where assembly \( U \)-factors, \( C \)-factors, and \( F \)-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/ISNEA 90.1 Appendix A.
- \(^b\) Where \( U \)-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The \( R \)-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.
- \(^c\) Where heated slabs are below grade, below-grade walls shall comply with the \( U \)-factor requirements for above-grade mass walls.
d. “Mass floors” shall be in accordance with Section C402.2.3.

Reason: The purpose of this code change proposal is to correct two errors in the U-factor for wall insulation in climate zones 5 and 7. In both cases, the U-factor does not match the corresponding R-value of the IECC. The proposal above not only brings the U-factor into alignment with the IECC R-value, but also brings it into alignment with the applicable U-factors and R-values in ASHRAE Standard 90.1-2016.

In climate zone 7, Group R metal-framed walls are required to be insulated to R-13+R-15.6 c.i. in both the IECC and ASHRAE Standard 90.1. ASHRAE Standard 90.1 includes an equivalent U-factor of 0.042, which corresponds with the R-value according to Standard 90.1 Normative Appendix A. However, the 2018 IECC includes an equivalent U-factor of 0.052, which is inconsistent. We believe the IECC U-factor is an error and should be changed to 0.042.

In climate zone 5, Group R wood-framed walls are required to be insulated to R-13+R-7.5 c.i., or R-20+R-3.8 c.i., but the U-factor equivalent clearly does not match up. ASHRAE Standard 90.1 specifies a U-factor of 0.051, which not only corresponds with the R-value, but also corresponds with the U-factor requirements in climate zones 6 and 7 (which also require R-13+5 + R-7.5 c.i., or R-20+R-3.8 c.i.). Here again, we believe the IECC U-factor is an error, and should be changed to 0.051.

The building envelope typically remains the same for many years after construction and it is particularly important to “get it right” at the time of construction. After all, the intent of the IECC (C101.3) is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The current U-factor equivalents for metal-framed walls in climate zone 7 and wood-framed walls in climate zone 5 are errors and are inconsistent with the R-value equivalent in Table C402.1.3.

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

**ci** = Continuous insulation, **NR** = No Requirement, **LS** = Liner System.

**a.** Where assembly **U**-factors, **C**-factors, and **F**-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

**b.** Where **U**-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The **R**-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

**c.** Where heated slabs are below grade, below-grade walls shall comply with the **U**-factor requirements for above-grade mass walls.

**d.** “Mass floors” shall be in accordance with Section C402.2.3.

**e.** These **C**-, **F**- and **U**-factors are based on assemblies that are not required to contain insulation.

**f.** The first value is for perimeter insulation and the second value is for full slab insulation.

**g.** “Mass walls” shall be in accordance with Section C402.2.2.

**Reason:** The **F**-factors for heated slabs in Table C402.1.4 are currently shown as two separate factors for the two insulation components. This is technically incorrect and has caused confusion for the following reasons:

1. **F**-factors are like **U**-factors in that they represent the net effect of all insulation materials applied to an assembly. Thus, there should only be one **F**-factor representing the **R**-value of any and all insulation materials used on the slab construction. In this case, one **F**-factor should be used to represent the combined effect of perimeter and full slab insulation **R**-values required in Table C402.1.3 for heated slabs.

2. For evaluating alternative insulation solutions (such as by using COMcheck), one must apply a single **F**-factor to the slab construction. Without this corrected in the code, making alternative solutions to the **R**-value table will become confused and potentially non-compliant or unavailable. For example, the revised **F**-factors as proposed are consistent with **F**-factors in the ASHRAE 90.1 standard’s Appendix A (pending final approval of Addendum bx) which is referenced in footnote ‘a’ of this Table C402.1.4. This consistency is important for code compliance and flexibility to determine alternate solutions. It is also for this reason that some of the **F**-factors have two significant digits while others have three – exactly as done in ASHRAE 90.1 Appendix A as already referenced in footnote ‘a’.
3. The current “dual” F-factors was the inadvertent outcome of last code cycle in attempting to do the best that could be done at that time to make a needed improvement to the code while reasonably resolving several competing proposals and public comments (see proposal CE61-16 (AMPC2) from last code cycle).

4. Footnote ‘f’ was developed as a “patch” for the 2018 code until a better F-factor solution could be developed as done in this current proposal. Thus, with the F-factor corrections in this proposal, footnote ‘f’ is no longer needed to give direction for appropriate use of a single F-factor to determine equivalent R-value requirements when insulation is used in multiple locations (e.g., at perimeter and fullslab). The means to determine alternative F-factors is already addressed in footnote ‘a’ referencing ASHRAE 90.1 Appendix A data.

This proposal resolves all of the above issues and will provide greater flexibility for compliance by providing a means to use a single F-factor to determine a variety of alternative R-values for any combination of perimeter and full-slab insulation, not just those shown in the R-value Table C402.1.3.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This proposal is a correction to the heated slab F-factors to ensure appropriate use, consistency with the R-value requirements (which combine perimeter and full-slab insulation), and to allow alternatives to be determined using tools like COMcheck and ASHRAE 90.1 Appendix A. It does not change the stringency of the requirements.
Proponent: Joseph Hetzel, representing Door & Access Systems Manufacturers Association (Jhetzel@thomasamc.com)

Garage door <14% glazing

|                  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  | U-0.31  |

For SI: 1 pound per square foot = 4.88 kg/m², 1 pound per cubic foot = 16 kg/m³.

**ci** = Continuous insulation, NR = No Requirement, LS = Liner System.

- **a.** Where assembly U-factors, C-factors, and F-factors are established in ANSI/ASHRAE/IESNA 90.1 Appendix A, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table, and provided that the construction, excluding the cladding system on walls, complies with the appropriate construction details from ANSI/ASHRAE/IESNA 90.1 Appendix A.

- **b.** Where U-factors have been established by testing in accordance with ASTM C1363, such opaque assemblies shall be a compliance alternative where those values meet the criteria of this table. The R-value of continuous insulation shall be permitted to be added to or subtracted from the original tested design.

- **c.** Where heated slabs are below grade, below-grade walls shall comply with the U-factor requirements for above-grade mass walls.

- **d.** “Mass floors” shall be in accordance with Section C402.2.3.

- **e.** These C-, F- and U-factors are based on assemblies that are not required to contain insulation.

- **f.** The first value is for perimeter insulation and the second value is for full slab insulation.

- **g.** “Mass walls” shall be in accordance with Section C402.2.2.

- **h.** Garage doors having a single row of fenestration shall have an assembly U-factor less than or equal to 0.44 in Climate Zones 1 through 6 and less than or equal to 0.36 in Climate Zones 7 and 8, provided that the fenestration area is not less than 14 percent and not more than 25 percent of the total door area.

**Reason:** This proposal clarifies U-factor requirements for garage doors with glazing making up between 14% and 25% of the door area. This footnote will complete the garage door U-factor requirements in the code, allowing for non-glazed (<14% glazing), vision lights or one row of glazing (14-25% glazing), or fenestration (>50% glazing) Garage doors are not designed with glazing constituting between 25% and 50% of the door area. The U-factor values in the proposed footnote are based on DASMA research involving one row of glazing in sectional doors.

**Cost Impact:** The code change proposal will decrease the cost of construction. The code change proposal will decrease the cost of construction. Currently, there is no prescriptive means of determining the maximum U-factor requirement for garage doors with between 14% and 25% glazing. If the U-factor requirement is obtained from the chart for garage doors with less than 14% glazing, or is obtained from the fenestration (greater than 50% glazing) charts, the values are unrealistically conservative. The proposed U-factors are based on sound testing, and the clarified requirements would theoretically lower...
construction costs.
CE78-19 Part I

PART I — IECC: C402.2.4, C402.2.4.1 (New)

PART II — IECC: R402.2.10 (IRC N1102.2.10), R402.2.10.1 [IRC N1102.2.10.1] (New)

Proponent: William Warlick, representing Self (william.warlick@slcgov.com); Don Davies (don.davies@slcgov.com)

2018 International Energy Conservation Code

Revise as follows:

C402.2.4 Slabs-on-grade perimeter insulation. Slab-on-grade floors (Mandatory). Where the slab on grade is in contact with the ground, the minimum thermal resistance (R-value) of the insulation around the perimeter of unheated or heated slab-on-grade floors. A slab-on-grade floor designed in accordance with the R-value method of Section C402.1.3 shall be as specified in Table C402.1.3. The perimeter insulation shall be placed on the outside of the foundation or on the inside of the foundation wall. The perimeter insulation shall extend downward from the top of the slab for the minimum distance shown in the table or to the top of the footing, whichever is less, or downward to not less than the bottom of the slab and then horizontally to the interior or exterior for the total distance shown in the table. Insulation extending away from the building shall be protected by pavement or by not less than of 10 inches (254 mm) of soil; insulated in accordance with this section and Table C402.1.3.

Exception: Where the slab-on-grade floor is greater than 24 inches (61 mm) below the finished exterior grade perimeter insulation is not required.

Add new text as follows:

C402.2.4.1 Construction. The insulation shall be placed around the foundation perimeter on the outside of the foundation or on the inside of the foundation wall. The perimeter insulation shall extend downward from the top of the slab for downward the minimum distance shown in Table C402.1.3 or to the top of the footing, whichever is less, or downward to not less than the bottom of the slab and then horizontally to the interior or exterior for the total distance shown in the table. Insulation extending away provided in Table C402.1.3 by any combination of vertical placement, extending under the slab or extending out from the building. Insulation extending out from the building shall be protected by pavement or by not less than of 10 inches (254 mm) of soil.

Exceptions:

1. In vertical placement the insulation shall be permitted to extend downward the distance shown in the table or to the top of the footing.
2. Preservative-treated wood or other approved thermal break material shall be permitted to substitute for the top 3-1/2 inches of insulation between the foundation wall and the edge of the floor slab.
3. Except at heated slabs or in a Group R occupancy, a thermal break of minimum ½ inch isolation joint material shall be permitted to substitute for the insulation between the foundation wall and the edge of the floor slab.
2018 International Energy Conservation Code

Revise as follows:

**R402.2.10 (IRC N1102.2.10) Slab-on-grade floors (Mandatory).** Slab-on-grade floors with a floor surface less than 12 inches (305 mm) below grade shall be insulated in accordance with this section and Table R402.1.2. The insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall. Insulation located below grade shall be extended the distance provided in Table R402.1.2 by any combination of vertical insulation, insulation extending under the slab or insulation extending out from the building. Insulation extending away from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall. Slab-edge insulation is not required in:

**Exceptions:**

1. Where the slab-on-grade floor is greater than 12 inches (30 mm) below the finished exterior grade.
2. In jurisdictions designated by the code official as having a very heavy termite infestation.

Add new text as follows:

**R402.2.10.1 (IRC N1102.2.10.1) Construction.** The insulation shall be placed around the foundation perimeter grade shall be insulated in accordance with Table R402.1.2. The insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall. Insulation located below grade shall be extended The insulation shall extend from the top of the slab downward the distance provided in Table R402.1.2 by any combination of vertical insulation placement, insulation extending under the slab or insulation extending out from the building. Insulation extending away out from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil.

**Exceptions:**

1. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall.
2. Preservative-treated wood or other approved thermal break material shall be permitted to substitute for the top 1-1/2 inches of insulation between the foundation wall and the edge of the floor slab.

Slab-edge insulation shall not be required in jurisdictions designated by the code official as having a very heavy termite infestation.

**Reason:** The intent of this code change proposal is to: (1) make the insulation of slab-on-grade floors mandatory; (2) provide alternative construction solutions for insulation run inside a foundation wall; and (3) simplify and harmonize the code language.

During the life expectancy of a building insulation can readily be added to most envelope portions of the building at times, but one envelope element which will not be upgraded is the slab-on-grade insulation. Therefore, it is
important to get this insulation done right when a new building is built.

While making slab-on-grade floor insulation mandatory could entail some construction problems, this code change offers practical solutions. And while the 45-degree angle cut option provided for residential buildings has proven to be impractical in some situations, the code change offers construction options to this. Where insulation is run inside the foundation wall the joint between the slab and the foundation can be covered by preservative-treated wood. In limited applications where occupant comfort will not be critical, this insulation can be substituted by simply a thermal break.

In addition to making these substantive changes, we propose new text to simplify and clarify the code language, and to harmonize the structure of this section across the IRC and IECC Commercial and Residential sections.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
Will not increase the cost of construction. Insulation provided at slab-on-grade floors would substitute for insulation at other elements of the thermal envelope, so the Mandatory provision would not add to the cost of construction.
Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee of the American Chemistry Council

2018 International Energy Conservation Code

C402.2.4 Slabs-on-grade perimeter insulation. Slabs-on-grade. (Prescriptive) Where the slab on grade is in contact with the ground, the minimum thermal resistance (R-value) of the insulation around the perimeter of unheated or heated slab-on-grade floors designed in accordance with the R-value method of Section C402.1.3 shall be as specified in Table C402.1.3. The perimeter insulation shall be placed on the outside of the foundation or on the inside of the foundation wall. The perimeter insulation shall extend downward from the top of the slab for the minimum distance shown in the table or to the top of the footing, whichever is less, or downward to not less than the bottom of the slab and then horizontally to the interior or exterior for the total distance shown in the table. Insulation extending away from the building shall be protected by pavement or by not less than of 10 inches (254 mm) of soil. Exception: Where the slab on-grade floor is greater than 24 inches (61 mm) below the finished exterior grade, perimeter insulation is not required.

Add new text as follows:

C402.2.4.1 Insulation installation (Mandatory). Where installed, the perimeter insulation shall be placed on the outside of the foundation or on the inside of the foundation wall. The perimeter insulation shall extend downward from the top of the slab for the minimum distance shown in the table or to the top of the footing, whichever is less, or downward to not less than the bottom of the slab and then horizontally to the interior or exterior for the total distance shown in the table. Insulation extending away from the building shall be protected by pavement or by not less than of 10 inches (254 mm) of soil. Where installed, full slab insulation shall be continuous under the entire area of the slab-on-grade floor, except at structural column locations and service penetrations. Insulation required at the heated slab perimeter shall not be required to extend below the bottom of the heated slab and shall be continuous with the full slab insulation. Exception: Where the slab-on-grade floor is greater than 24 inches (61 mm) below the finished exterior grade, perimeter insulation is not required.

Reason: In the last code cycle, provisions for full-slab insulation where added to Table C402.1.3 for heated slabs. However, Section C402.2.4 only addresses perimeter insulation of slabs. This proposal makes coordinating changes to Section C402.2.4 such that installation of both perimeter insulation and full-slab insulation are addressed in a manner consistent with the intent of Table C402.1.3. The designation of [Prescriptive] and [Mandatory] in the titles is used because the R-values are prescriptive, but the installation requirements should apply to any and all compliance approaches (i.e., mandatory). This approach is also intended to be consistent with a larger proposal expected from SEHPCAC which addresses the prescriptive vs. mandatory matter in other sections of the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal adds installation provisions for full-slab insulation in a manner consistent with Table C402.1.3. The installation provisions provided for full slab insulation may reduce cost for typical slab-on-grade floor construction by explicitly not requiring insulation under structural column footings (although this is possible using high density and compressive strength foam insulating sheathing boards as commonly done for cryogenic facilities and infrastructure frost protection).

Staff Analysis: Please note that the majority of the change is relocating existing text from Section C402.2.4 into C402.2.4.1. Because of the requirements of the cdpACCESS system, the text removed from C402.2.4 must be
shown as deleted and then underlined when it reappears in Section C402.2.4.1
CE80-19

IECC: C401.2, C402.2.7, C407.2

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402 through C405 and C408. In addition, commercial buildings shall comply with Section C406 and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Sections C402.2.7, C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404, C405, C407 and C408. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

C402.2.7 Airspaces. Airspaces (Mandatory). Where the thermal properties of airspaces are used to comply with this code R-value of an airspace is used for compliance in accordance with Section C401.2, such airspaces C402.1 the airspace shall be enclosed in an unventilated cavity constructed to minimize airflow into and out of the enclosed airspace. Airflow shall be deemed minimized where the enclosed airspace is located on the interior side of the continuous air barrier and is bounded on all sides by building components.

Exception: The thermal resistance of airspaces located on the exterior side of the continuous air barrier and adjacent to and behind the exterior wall-covering material shall be determined in accordance with ASTM C1363 modified with an airflow entering the bottom and exiting the top of the airspace at an air movement rate of not less than 70 mm/second.

C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.2.7, C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.

Reason: When C402.2.7 was added in the 2018 edition of the code it required compliance with C401.2, but did not exclude the ASHRAE 90.1 compliance path. Imposing the airspace requirement on designs which do not use Chapter 4, but use ASHRAE 90.1 prevents the 90.1 path from being a standalone path as intended. This is an opportunity for conflict and confusion and complicates training for both the IECC and the 90.1. The reference "in accordance with Section C401.2" could be read to imply that this requirement overlays those of ASHRAE 90.1. The IECC does not make modifications to the ASHRAE 90.1.

Airspaces are proposed to be non-tradeable (mandatory) in the performance path because the IECC’s provisions do not include performance metrics, indicating there is no tradable value.

Instead, the IECC’s requirements for airspaces are installation related – ‘how to do an airspace’- which apply to all installations, prescriptive and performance, which makes the provision mandatory.

While identified as "Mandatory", if the elimination of the use of the labels "prescriptive "and "mandatory" is approved, we understand this label would not be added and it would instead the provision be added to Table C407.2 to indicate its application to the Total Building Performance compliance option.
This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This change does not increase or decrease code provisions nor impact construction methods. It clarifies language and provisions already contained in the code.

 Proposal # 4182

CE80-19
2018 International Energy Conservation Code

Revise as follows:

C402.2 Specific building thermal envelope insulation requirements (Prescriptive). Insulation in building thermal envelope opaque assemblies shall comply with Sections C402.2.1 through C402.2.7 and Table C402.1.3.

Add new text as follows:

C402.2.8 Concrete slab floors. Concrete floor slabs that penetrate the building thermal envelope shall be provided with either continuous insulation having a minimum thermal resistance of R-3 or a minimum R-3 thermal break located where the concrete slab penetrates the building thermal envelope.

Reason: The requirements for overall assembly insulation have been well-addressed in the code. However, the existing requirements do not adequately address significant thermal bridging issues. Thermal bridges are created when a relatively high thermally conductive material "bridges" through the insulating materials in the thermal envelope. Whether they penetrate all the way from the exterior to the interior of the building or only partially through the thermal envelope, thermal bridges make it easier for heat to travel in or out of the building. The impact of thermal bridges has a greater energy impact than a simple weighted U-factor calculation would suggest. Weighted U-factor calculations assume that heat travels in parallel paths through an assembly. In reality, heat also moves laterally, resulting in additional heat transmission through the assembly.

This has an impact on the heating and cooling loads of the building, as well as on the perceived comfort of space occupants. Humans perceive heat primarily through conduction, then radiation, then convection. So the presence of hot or cold surfaces due to thermal bridges can have a significant impact on thermal comfort. When the thermal envelope has hot or cold spots from thermal bridges, occupants are more likely to feel uncomfortable and respond by over-conditioning the air in the space, creating another source of energy loss.

The common practices of leaving concrete slab floor edges un-insulated and extending structural slabs through the thermal envelope to create balconies are particularly problematic and significant thermal bridges. This proposal addresses this significant issue by requiring that the thermal bridges created by concrete floor slabs...
that penetrate the building thermal envelope be addressed either by providing them with thermal breaks or by encapsulating them in continuous insulation. There are products available on the market that can be used to provide a thermal break within a continuously poured slab that extends to create a balcony. Alternately, balconies can utilize alternate structural configurations that do not require turning the building into a huge radiator.

**Cost Impact:** The code change proposal will increase the cost of construction
This will increase the cost of construction. Cost impact will vary depending on the approach taken.
2018 International Energy Conservation Code

Add new definition as follows:

VEGETATIVE ROOF. An assembly of interacting components designed to waterproof a building’s top surface that includes, by design, vegetation and related landscape elements.

Revise as follows:

C402.3 Roof solar reflectance and thermal emittance. Low-sloped roofs directly above cooled conditioned spaces in Climate Zones 1, 2 and 3 shall comply with one or more of the options in Table C402.3.

Exceptions: The following roofs and portions of roofs are exempt from the requirements of Table C402.3:

1. Portions of the roof that include or are covered by the following:
   1.1. Photovoltaic systems or components.
   1.2. Solar air or water-heating systems or components.
   1.3. Vegetative roofs, roof gardens or landscaped roofs.
   1.4. Above-roof decks or walkways.
   1.5. Skylights.
   1.6. HVAC systems and components, and other opaque objects mounted above the roof.

2. Portions of the roof shaded during the peak sun angle on the summer solstice by permanent features of the building or by permanent features of adjacent buildings.

3. Portions of roofs that are ballasted with a minimum stone ballast of 17 pounds per square foot [74 kg/m²] or 23 psf [117 kg/m²] pavers.

4. Roofs where not less than 75 percent of the roof area complies with one or more of the exceptions to this section.

Reason: The purpose of this proposal is to maintain consistency in terminology throughout the ICC Family of International Codes. The term vegetative roof is used and defined in the 2018 IBC Ch. 2, 15, 16 and the 2018 IECC Appendix CA, entitled Solar-Ready Zone—Commercial. The proposal retains the terms roof garden and landscaped roof consistent with similar retentions in the aforementioned I-Code references.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification and consistency across DEFINITIONS used in the ICC Family of International Codes. No change to stringency is proposed.

a. “N” indicates vertical fenestration oriented within 45 degrees of true north. “SEW” indicates orientations other than “N.” For buildings in the southern hemisphere, reverse south and north. Buildings located at less than 23.5 degrees latitude shall use SEW for all orientations.

**Reason:** The purpose of this proposal is to update the fenestration criteria based on a recent comprehensive analysis, providing additional energy savings in every zone while remaining cost-effective and practical. This
The fenestration energy performance indices (U-factor, SHGC), incremental costs, and energy savings associated with a total of 319 fenestration assemblies using different glazing, frame, spacer, and gas fill technologies were calculated to determine what performance levels showed positive life cycle energy savings in each zone using a heating scalar of 25.2 and a cooling scalar of 22.1, consistent with ASHRAE 90.1 methodology. Energy savings for different combinations of U and SHGC were calculated using the medium office and midrise apartment prototype building models developed by Pacific Northwest National Laboratory. Incremental cost data for each product combination was reviewed in consultation with the ASHRAE 90.1 Envelope Subcommittee, industry representatives, and other stakeholders. Practical considerations of potential limitations of different technologies in different applications, distinctions between product categories, product costs, supply and distribution were also used in shaping the final proposed requirements. This analysis resulted in the comprehensive update to ASHRAE 90.1 in Addendum AW, and those same values are adapted into IECC's different table format in this proposal.

Depending on zone, U-factors are reduced by 0-14% for fixed and operable vertical fenestration, 7-25% for entrance doors, and 0-18% for skylights; SHGC requirements for vertical fenestration and skylights are reduced by 0-14%. Overall, this proposal provides the next step in energy efficiency while relying on commercially available and cost-effective technologies, including increased use of new low-e glass coatings, high performance thermally broken or composite frames, argon gas fill, and warm edge spacers. Additionally, consistency between IECC and ASHRAE 90.1 will improve use and compliance of both standards for the design community, fenestration industry, and building code officials.

**Cost Impact:** The code change proposal will increase the cost of construction

As described above, the ASHRAE 90.1 fenestration workgroup and envelope subcommittee assessed the incremental cost, energy savings, and life cycle cost effectiveness for 319 fenestration assemblies using a wide range of commercially available technologies: 37 different glazing assemblies (double, triple glazing with different low-e products), 4 levels of frame performance, 3 levels of spacer performance, and 2 different gas fills. Incremental cost data for each product combination was reviewed in consultation with the ASHRAE 90.1 Envelope Subcommittee, industry representatives, and other stakeholders. Life cycle energy savings were assessed in the PNNL medium office and midrise apartment prototype building models in each climate zone using a heating scalar of 25.2 and a cooling scalar of 22.1, and the proposed changes showed positive life cycle energy savings in accordance with ASHRAE 90.1 methodology.

Life cycle analysis was the primary method for determination of cost effectiveness. Nonetheless, simple payback periods for the PNNL medium office building typically ranges from 0-16 years in zones 1-7, and approximately 24 years in zone 8 where the jump from double to triple glazing in the model building increases the apparent payback period. In reality, triple glazing is already common in this extremely cold region (e.g. north slope of Alaska).

NR = No Requirement, PF = Projection Factor.

a. “N” indicates vertical fenestration oriented within 45 degrees of true north. “SEW” indicates orientations other than “N.” For buildings in the southern hemisphere, reverse south and north. Buildings located at less than 23.5 degrees latitude shall use SEW for all orientations.

Reason: The purpose of this code change proposal is to upgrade and improve U-factors for fixed and operable vertical fenestration and entrance doors in order to save energy and reduce energy cost and peak demand, consistent with the recently approved Addendum aw to ASHRAE Standard 90.1-2016, which will be part of ASHRAE Standard 90.1-2019. This proposal will improve efficiency in every climate zone, resulting in additional cost-effective energy cost savings for owners and lessors of commercial buildings and improving comfort for occupants of these buildings.
Beginning with the 2012 IECC, and continuing through subsequent editions of the code, the IECC has set U-factor requirements that properly apply irrespective of frame material type. Instead, the IECC distinguishes only between fixed and operable vertical fenestration U-factors, regardless of frame material. This change led to several positive outcomes in the IECC: (1) It improved efficiency overall in commercial buildings; (2) it greatly simplified compliance; and (3) it eliminated the unfairness from differing requirements depending on frame material type that fueled opposition by some in the window industry. Over that same period, ASHRAE continued to set U-factors specific to framing material: one set of U-factors for metal-framed products and one set for nonmetal-framed products. This has led to conflicting requirements and confusion at the state level, since the vast majority of states adopt the IECC as the primary commercial energy code, but allow compliance with ASHRAE Standard 90.1 as an alternative.

Addendum aw, which will become part of ASHRAE Standard 90.1-2019, will finally bring ASHRAE into general alignment with the IECC on this front by eliminating requirements that vary by framing material in favor of material-neutral “fixed” and “operable” requirements consistent with the approach already used in the IECC. This will not only help reduce confusion among design professionals, builders and code enforcement officials, but will also provide more consistent efficiency targets to fenestration manufacturers and contractors. It will also make it easier to promote the adoption of the latest model energy codes in state and local jurisdictions by removing these conflicting provisions from ASHRAE Standard 90.1. Given the recent improvement in ASHRAE values and the role of ASHRAE Standard 90.1 in the DOE commercial energy code determination process, it is now very important to improve IECC U-factors to at least match improved ASHRAE values. As a result, approving this code change proposal will help ensure consistency between the ASHRAE and IECC vertical fenestration U-factor tables for the first time since 2012 while making sure the IECC meets or exceeds ASHRAE fenestration requirements.

This proposal will also improve energy savings in commercial buildings by adopting Addendum aw's moderate improvements to fenestration U-factors. These improvements are the result of significant cost and economic analyses undertaken as part of ASHRAE’s process, and Addendum aw was approved with broad support from manufacturers, efficiency advocates, and other stakeholders in commercial building efficiency. Improvements to the thermal envelope are a critical part of the IECC’s drive toward more efficient buildings. The efficiency of the building thermal envelope is, for the most part, set at construction, and the impact of decisions made regarding the thermal envelope will affect the building’s performance for decades. While the energy savings of this update will vary somewhat based on product type and climate zone, the overall impact on energy and cost savings from this proposal is clearly positive as found by ASHRAE.

**Cost Impact:** The code change proposal will increase the cost of construction

Given the broad range of building types within the scope of the IECC, as well as the many products available to meet or exceed these U-factors, the cost impact will vary somewhat from one project to the next. Overall, we expect the cost impact to be very small. In some cases, it may simply be a matter of selecting a different product already available, with no cost difference at all. Our understanding is that each U-factor selected by ASHRAE for Addendum aw has gone through a rigorous energy-savings and cost-effectiveness analysis, so even in cases where construction costs are increased, the improvements will be cost-effective and beneficial over the useful life of the product.

NR = No Requirement, PF = Projection Factor.

a. “N” indicates vertical fenestration oriented within 45 degrees of true north. “SEW” indicates orientations other than “N.” For buildings in the southern hemisphere, reverse south and north. Buildings located at less than 23.5 degrees latitude shall use SEW for all orientations.

Reason: The purpose of this code change proposal is to improve skylight U-factors in the IECC consistent with recent changes to be incorporated into ASHRAE Standard 90.1-2019 and to bring additional cost-effective energy savings to owners of commercial buildings with skylights in climate zones 1 and 6 through 8. The U-factors in this proposal reflect those approved for Addendum aw to ASHRAE Standard 90.1-2016, which will be part of the published Standard 90.1-2019 (which we expect will be referenced as an acceptable compliance option in the 2021 IECC section C401.2). Establishing consistency with ASHRAE’s skylight U-factors will not only
reduce confusion among design professionals and building officials but will also provide building owners with more efficient skylights determined to be cost-effective through ASHRAE’s process.

**Cost Impact:** The code change proposal will increase the cost of construction
While we believe that many skylights currently being installed will already meet or exceed these U-factor requirements, in some cases, the lower U-factors will require the selection of a more efficient skylight or the incorporation of other energy efficient measures in the IECC’s performance-based compliance options, either of which may increase costs. Although these improvements in skylight U-factors may increase costs in climate zones 1 and 6-8, we do not expect the cost increases to be significant. Our understanding is that each U-factor selected by ASHRAE for Addendum aw has gone through a rigorous energy-savings and cost-effectiveness analysis, so even in cases where construction costs are increased, the improvements will be cost-effective over the useful life of the product.

NR = No Requirement, PF = Projection Factor.

---

**Note:**
- “N” indicates vertical fenestration oriented within 45 degrees of true north. “SEW” indicates orientations other than “N.” For buildings in the southern hemisphere, reverse south and north. Buildings located at less than 23.5 degrees latitude shall use SEW for all orientations.
Reason: The purpose of this code change proposal is to save energy, reduce energy costs and peak demand, and enhance occupant comfort by improving commercial fenestration SHGCs and making the IECC’s treatment reasonably consistent with Addendum aw to ASHRAE Standard 90.1-2016, which will be part of the published Standard 90.1-2019. The proposal also greatly simplifies compliance with the prescriptive fenestration SHGC requirements in the IECC by adopting ASHRAE’s “fixed” and “operable” approach to setting SHGC requirements, in lieu of requiring the user to determine the orientation of each fenestration product in the building in order to apply the IECC’s current orientation-specific SHGCs. This proposal also maintains projection factor adjustments that are consistent with the current IECC approach but adjusts them according to the new “fixed” and “operable” distinction. These changes will result in energy savings and peak demand savings in every climate zone, and in many cases may reduce the size of cooling equipment. The proposal will also bring greater consistency between IECC and ASHRAE SHGC requirements while reducing unnecessary confusion. The commercial IECC’s prescriptive approach of incorporating orientation into its SHGC requirement has been unnecessarily complicated in recent years, and it has not provided any real efficiency or compliance benefits. The residential IECC prescriptive path has always applied a single SHGC to fenestration in each climate zone, irrespective of orientation, leaving more sophisticated design choices to the performance path, where it is more appropriate. By contrast, recent editions of the IECC have established orientation-specific SHGCs in the commercial prescriptive path by increasing the SHGC (and reducing efficiency) for northern orientations. The current SHGC division between South/East/West on one hand, and North-facing fenestration on the other, is unnecessary, less efficient, and too complicated for a prescriptive path that is most often used for simple commercial and multifamily buildings. To the extent that design professionals want to incorporate a more sophisticated solar design into a building, a performance compliance approach is a far more appropriate compliance path for such a design. The current orientation-specific SHGCs promote the idea that a design professional should incorporate a higher SHGC on the north-facing walls—an approach that is not only unlikely in practice, but potentially risky, since the wrong windows may be installed on the wrong side of the building. (Note that higher SHGCs on the north side are also less efficient; while a low SHGC is more beneficial on the other orientations, lower SHGCs provide benefits on north orientations as well.)

A better approach has been charted by ASHRAE in Addendum aw. ASHRAE sets SHGC requirements based on whether the fenestration is fixed or operable, since operable fenestration typically has larger frames and lower unit SHGCs as a result. ASHRAE does not differentiate the prescriptive SHGC requirements by orientation and has not set an artificially high and unrealistic SHGC for north-facing fenestration, recognizing that the lower SHGC is cost-effective on any side of the building. This approach has the added benefit of improving north-oriented fenestration SHGCs; these lower SHGCs were found by ASHRAE to be cost-effective (there is likely no additional cost associated with the improved SHGCs given the U-factor requirements).

While we would prefer even lower SHGCs in some climate zones, this proposal improves the SHGCs in every climate zone to varying degrees and is a step in the right direction. Low-SHGC fenestration is critically important in commercial buildings because of high daytime occupancy rates and higher internal thermal loads. Reducing solar heat gain will improve occupant comfort and may allow for the installation of smaller cooling equipment, which will not only save building owners money at construction, but again every time the equipment is replaced. Widespread use of low-SHGC fenestration (and the accompanying peak reduction) will also help reduce the need for utilities to build peaking plants or purchase peak electric power, which will ultimately benefit all utility ratepayers.

Cost Impact: The code change proposal will increase the cost of construction. While we believe that many windows currently being installed will already meet or exceed these SHGC requirements, in some cases, the lower SHGCs will require the selection of a more efficient window or the incorporation of other energy efficient measures in the IECC’s performance-based compliance options, either of which may increase costs. However, since the SHGC is largely just the result of the choice of low-e coating, there may be no additional cost in most cases. Moreover, any increased glass costs may be more than offset by reduced cooling equipment costs in many cases. In any event, these SHGC values have all been thoroughly
considered in ASHRAE’s energy and cost-effectiveness analyses. To the extent that the lower SHGCs increase construction costs, based on ASHRAE’s work, we expect that these improvements are cost-effective over the useful life of the building.

NR = No Requirement, PF = Projection Factor.

a. “N” indicates vertical fenestration oriented within 45 degrees of true north. “SEW” indicates orientations other than “N.” For buildings in the southern hemisphere, reverse south and north. Buildings located at less than 23.5 degrees latitude shall use SEW for all orientations.

**Reason:** The proposal modifies the fenestration table by separating requirements for “punched opening” type windows that go in a framed opening from other fenestration types such as metal curtain walls, storefront fenestration and site-build fenestration. Punched opening windows can achieve better U-factors more easily and cost-effectively than the other fenestration types, but U-factor code requirements for this window type have been held back by the technological and cost effectiveness limitations of curtain wall fenestration systems, storefronts and site-built products.
The 2018 IECC currently allows a 4 story multifamily building to install a less efficient window than an otherwise identical 3-story multifamily building. The only difference in the buildings from an energy standpoint is the number of floors, yet less efficient windows are allowed to be installed in the mid-rise building. This is a critical issue for midrise multifamily buildings where punched opening type windows are common, but is also an issue for other low- and mid-rise commercial buildings where they are also common.

This proposal is meant to close this loophole. It retains existing U-factor requirements for curtain walls, storefront fenestration, site-built fenestration and entrance doors (the types for which U-factor advancements are more difficult) and introduces a new category for all other fenestration that captures punched opening windows. The U-factor requirements for this category are drawn from the residential section of the code since punched opening requirements are the standard fenestration type in residential construction.

It is important to note that this proposal has been structured in a way so that it will be compatible with any other proposal that changes the existing U-factors. This proposal changes the headings and leaves the actual U-factors in place, allowing them to be modified by another proposal.

There may be some specialized circumstances where these requirements could cause technical challenges, especially high-rise buildings that are utilizing punched openings or other high-wind areas. However, this table sets the minimum for performance and these projects have other compliance paths (both modeling in the IECC and ASHRAE 90.1) to give them flexibility for these specialized circumstances, and it does not make sense to hold back the performance of the entire new construction building market for a handful of rare cases that still have other compliance options.

When these requirements were modeled relative to IECC-2015 (which has essentially the same window requirements), using the mid-rise prototype that the Pacific Northwest National Lab developed for national code determination studies, the savings ranged from 1.0-2.9% depending on climate zone (climate zone 1 is effectively the same).

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal will only increase cost for projects utilizing punched opening type fenestration. All other fenestration will be unaffected. Additionally, this proposal utilizes the values for punched openings from the the residential energy code requirements where these values have been negotiated through the ICC hearing process and found cost effective in residential.

IECC: C402.4.1.2, C402.4.2, C402.4.4, C405.2.3, C405.2.3.1, C405.2.3.2, FIGURE C405.2.3.2, C405.2.3.3, FIGURE C405.2.3.3(1)

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C402.4 Fenestration (Prescriptive). Fenestration shall comply with Sections C402.4.1 through C402.4.5 and Table C402.4. Daylight responsive controls shall comply with this section and Section C405.2.3.1.

C402.4.1.2 Increased skylight area with daylight responsive controls. The skylight area shall be not more than 6 percent of the roof area provided that daylight responsive controls complying with Section C405.2.3.1 are installed in toplit daylight zones.

C402.4.2 Minimum skylight fenestration area. In an enclosed space greater than 2,500 square feet (232 m²) in floor area, directly under a roof with not less than 75 percent of the ceiling area with a ceiling height greater than 15 feet (4572 mm), and used as an office, lobby, atrium, concourse, corridor, storage space, gymnasium/exercise center, convention center, automotive service area, space where manufacturing occurs, nonrefrigerated warehouse, retail store, distribution/sorting area, transportation depot or workshop, the total toplit daylight zone shall be not less than half the floor area and shall provide one of the following:

1. A minimum skylight area to toplit daylight zone of not less than 3 percent where all skylights have a VT of not less than 0.40 as determined in accordance with Section C303.1.3.
2. A minimum skylight effective aperture of not less than 1 percent, determined in accordance with Equation 4-4:

\[
\text{Skylight Effective Aperture} = \frac{0.85 \times \text{Skylight Area} \times \text{Skylight VT} \times \text{WF}}{\text{Toplit Zone}}
\]

(Equation 4-4)

where:

Skylight area = Total fenestration area of skylights.

Skylight VT = Area weighted average visible transmittance of skylights.

WF = Area weighted average well factor, where well factor is 0.9 if light well depth is less than 2 feet (610 mm), or 0.7 if light well depth is 2 feet (610 mm) or greater.

Light well depth = Measure vertically from the underside of the lowest point of the skylight glazing to the ceiling plane under the skylight.

Exception: Skylights above daylight zones of enclosed spaces are not required in:

2. Spaces where the designed general lighting power densities are less than 0.5 W/ft² (5.4 W/m²).
3. Areas where it is documented that existing structures or natural objects block direct beam sunlight on not less than half of the roof over the enclosed area for more than 1,500 daytime hours per year between 8 a.m. and 4 p.m.

4. Spaces where the daylight zone under rooftop monitors is greater than 50 percent of the enclosed space floor area.

5. Spaces where the total area minus the area of sidelit daylight zones is less than 2,500 square feet (232 m²), and where the lighting is controlled in accordance with Section C405.2.3.

C402.4.4 Daylight zones. Daylight zones referenced in Sections C402.4.1.1 through C402.4.3.2 shall comply with Sections C405.2.3.2 and C405.2.3.3, as applicable. Daylight zones shall include toplit daylight zones and sidelit daylight zones.

C405.2.3 Daylight-responsive controls. Daylight-responsive controls complying with Section C405.2.3.1 shall be provided to control the electric lights within daylight zones in the following spaces:

1. Spaces with a total of more than 150 watts of general lighting within sidelit daylight zones complying with Section C405.2.3.2. General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4.

2. Spaces with a total of more than 150 watts of general lighting within toplit daylight zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.

2. Lighting that is required to have specific application control in accordance with Section C405.2.4.

3. Sidelit daylight zones on the first floor above grade in Group A-2 and Group M occupancies.

4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance (LPA_{adj}) calculated in accordance with Equation 4-9

\[
LPA_{adj} = \left[ \frac{LPA_{norm} \times (1.0 - 0.4 \times \text{UDZFA} / \text{TBFA})}{\text{TBFA}} \right]
\]

(Equation 4-9)

where:

- \(LPA_{adj}\) = Adjusted building interior lighting power allowance in watts.
- \(LPA_{norm}\) = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.

- UDZFA = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.

- TBFA = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

C405.2.3.1 Daylight-responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:
1. Lights in toplit daylight zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit daylight zones in accordance with Section C405.2.3.2.

2. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.

3. Calibration mechanisms shall be in a location with ready access.

4. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light output or lower.

5. Daylight responsive controls shall be configured to completely shut off all controlled lights.

6. Lights in sidelit daylight zones in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

**Exception**: Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

C405.2.3.2 Sidelit daylight zone. The sidelit daylight zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit daylight zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.2.2.2.

2. The area of the fenestration is not less than 24 square feet (2.23 m²).

3. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.

4. The visible transmittance of the fenestration is not less than 0.20.
C405.2.3.3 Toplit daylight zone. The toplit daylight zone is the floor area underneath a roof fenestration assembly that complies with all of the following:

1. The toplit daylight zone shall extend laterally and longitudinally beyond the edge of the roof fenestration assembly to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.7 times the ceiling height, whichever is less, as indicated in Figure C405.2.3.3(1).

2. Where the fenestration is located in a rooftop monitor, the toplit zone shall extend laterally to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 1.0 times the height from the floor to the bottom of the fenestration, whichever is less, and longitudinally from the edge of the fenestration to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.25 times the height from the floor to the bottom of the fenestration, whichever is less, as indicated in Figures C405.2.3.3(2) and C405.2.3.3(3).

3. Direct sunlight is not blocked from hitting the roof fenestration assembly at the peak solar angle on the summer solstice by buildings or geological formations.

4. The product of the visible transmittance of the roof fenestration assembly and the area of the rough opening of the roof fenestration assembly divided by the area of the toplit zone is not less than 0.008.
FIGURE C405.2.3.3(1)
TOPLIT DAYLIGHT ZONE

Reason: Daylight zone and daylight responsive control are defined terms. Sidelit and toplit describe different types of daylight zones, but are not themselves defined terms and should not be italicized.

“Access” is a defined term, but is used in Section C405.2.3.2 for its’ common English meaning and should not be italicized.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is entirely editorial.

Proposal # 4990

CE89-19
2018 International Energy Conservation Code

Revise as follows:

C402.4 Fenestration (Prescriptive). Fenestration shall comply with Sections C402.4.1 through C402.4.5 and Table C402.4. Daylight responsive controls shall comply with this section and Section C405.2.3.1. C405.2.3.

C402.4.1.1 Increased vertical fenestration area with daylight responsive controls. In Climate Zones 1 through 6, not more than 40 percent of the gross above-grade wall area shall be vertical fenestration, provided that all of the following requirements are met:

1. In buildings not greater than two stories above grade, not less than 50 percent of the net floor area is within a daylight zone.
2. In buildings three or more stories above grade, not less than 25 percent of the net floor area is within a daylight zone.
3. Daylight responsive controls complying with Section C405.2.3.1 are installed in daylight zones.
4. Visible transmittance (VT) of vertical fenestration is not less than 1.1 times solar heat gain coefficient (SHGC).

Exception: Fenestration that is outside the scope of NFRC 200 is not required to comply with Item 4.

C402.4.1.2 Increased skylight area with daylight responsive controls. The skylight area shall be not more than 6 percent of the roof area provided that daylight responsive controls complying with Section C405.2.3.1 are installed in toplit zones.

C402.4.2.1 Lighting controls in toplit daylight zones. Daylight responsive controls complying with Section C405.2.3.1 shall be provided to control all electric lights within toplit zones.

Reason: These revisions correct the section reference number from C405.2.3.1 Daylight Responsive Controls Function to C405.2.3 Daylight responsive controls. This clarifies that the list of exceptions under C405.2.3 is applicable here.

Under C402.4.2.1 the phrase “to control all electric lights” is redundant when the section reference is updated from C405.2.3.1 to C405.2.3.

In general we have found these references to lighting controls requirements in the envelope section to be problematic in the past, where they seem to require that daylight responsive controls are required in applications which are exempt from daylight responsive controls in the lighting controls section.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change is editorial
CE91-19
IECC: C402.4.1.2, C402.4.2

Proponent: Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@jhatfieldandassociates.com)

2018 International Energy Conservation Code

Revise as follows:

C402.4.1.2 Increased skylight area with daylight responsive controls. The **Where daylight responsive controls complying with Section C405.2.3.1 are provided in toplit zones, the allowed skylight area shall be not more than 6 percent of the gross roof area provided that daylight responsive controls complying with Section C405.2.3.1 are installed in toplit zones, or that required for compliance with Section C402.4.2, whichever is greater.**

C402.4.2 Minimum skylight fenestration area. In an enclosed space **Skylights shall be provided in enclosed spaces greater than 2,500 square feet (232 m²) in floor area, directly under a roof with not less than 75 percent of the ceiling area with a ceiling height greater than 15 feet (4572 mm), and used as an office, lobby, atrium, concourse, corridor, storage space, gymnasium/exercise center, convention center, automotive service area, space where manufacturing occurs, nonrefrigerated warehouse, retail store, distribution/sorting area, transportation depot or workshop,** the total toplit daylight zone shall be not less than half the floor area and shall provide comply with one of the following:

1. A minimum skylight area to toplit daylight zone of not less than 3 percent where all skylights have a VT of not less than 0.40 as determined in accordance with Section C303.1.3.
2. A minimum skylight effective aperture of not less than 1 percent, determined in accordance with Equation 4-4.

\[
\text{Skylight Effective Aperture} = \frac{0.85 \times \text{Skylight Area} \times \text{Skylight VT} \times WF}{\text{Toplit Zone}}
\]

(Equation 4-4)

where:

Skylight area = Total fenestration area of skylights.

Skylight VT = Area weighted average visible transmittance of skylights.

WF = Area weighted average well factor, where well factor is 0.9 if light well depth is less than 2 feet (610 mm), or 0.7 if light well depth is 2 feet (610 mm) or greater.

Light well depth = Measure vertically from the underside of the lowest point of the skylight glazing to the ceiling plane under the skylight.

Exception: Skylights above daylight zones of enclosed spaces are not required in:

2. Spaces where the designed general lighting power densities are less than 0.5 W/ft² (5.4 W/m²).
3. Areas where it is documented that existing structures or natural objects block direct beam sunlight on not less than half of the roof over the enclosed area for more than 1,500 daytime
4. Spaces where the daylight zone under rooftop monitors is greater than 50 percent of the enclosed space floor area.
5. Spaces where the total area minus the area of sidelight daylight zones is less than 2,500 square feet (232 m²), and where the lighting is controlled in accordance with Section C405.2.3.

**Reason:** In both sections being modified, the proposal provides clearer and more direct language for the user. In section C402.4.1.2 the 6% limit remains but also allows for compliance with the minimum skylight fenestration area in C402.4.2, whichever is greater. There is no substantive change in C402.4.2, changes are being offered for clarity only.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The intent of the proposal is to coordinate the provisions for maximum and minimum skylights and to provide clarity in the language for the user. The clarity may result in more or fewer skylights in certain designs, but should not affect the cost of construction.

Proposal # 4416
2018 International Energy Conservation Code

Revise as follows:

**C402.4.2 Minimum skylight fenestration area.** In an enclosed space greater than 2,500 square feet (232 m²) in floor area, directly under a roof with not less than 75 percent of the ceiling area with a ceiling height greater than 15 feet (4572 mm), and used as an office, lobby, atrium, concourse, corridor, storage space, gymnasium/exercise center, convention center, automotive service area, space where manufacturing occurs, nonrefrigerated warehouse, retail store, distribution/sorting area, transportation depot or workshop, the total **toplit daylight zone** shall be not less than half the floor area and shall provide one of the following:

1. A minimum skylight area to **toplit daylight zone** of not less than 3 percent where all skylights have a VT of not less than 0.40 as determined in accordance with Section C303.1.3.
2. A minimum skylight effective aperture of not less than 1 percent, determined in accordance with Equation 4-4.

\[
\text{Skylight Effective Aperture} = \frac{0.85 \times \text{Skylight Area} \times \text{Skylight VT} \times WF}{\text{Toplit Zone}}
\]

(Equation 4-4)

where:

- **Skylight area** = Total fenestration area of skylights.
- **Skylight VT** = Area weighted average visible transmittance of skylights.
- WF = Area weighted average well factor, where well factor is 0.9 if light well depth is less than 2 feet (610 mm), or 0.7 if light well depth is 2 feet (610 mm) or greater.

- **Light well depth** = Measure vertically from the underside of the lowest point of the skylight glazing to the ceiling plane under the skylight.

**Exception:** Skylights above **daylight zones** of enclosed spaces are not required in:

1. Buildings in **Climate Zones** 6 through 8.
2. Spaces where the designed general lighting power densities are less than 0.5 W/ft² (5.4 W/m²).
3. Areas where it is documented that existing structures or natural objects block direct beam sunlight on not less than half of the roof over the enclosed area for more than 1,500 daytime hours per year between 8 a.m. and 4 p.m.
4. Spaces where the daylight zone under rooftop monitors is greater than 50 percent of the enclosed space floor area.
5. Spaces where the total area minus the area of sidelight daylight zones is less than 2,500 square feet (232 m²), and where the lighting is controlled in accordance with Section C405.2.3.
6. Spaces designed as storm shelters complying with ICC 500.
ICC 500: ICC/NSSA Standard for the Design and Construction of Storm Shelters

**Reason:** This proposal is submitted by the National Storm Shelter Association (NSSA) and the ICC 500 Storm Shelter Standard Development committee. The ICC 500 Standards Development committee is responsible for the development of the ICC/NSSA Standard for the Design and Construction of Storm Shelters. The committee is currently working on the development of the 2020 edition. In 2017 the ICC 500 committee held 7 open conference calls. In addition, there were numerous Working Group meetings and conference calls, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: [https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm](https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm).

NSSA was responsible for the development of the original standard for storm shelters in 2001, which ICC 500 replaced through an agreement between ICC and NSSA. Representing General, User and Producer interest categories, NSSA is a technical organization that is committed to promoting consistent quality in both residential and community storm shelters.

A popular style of storm shelter for schools is to use a practice gymnasium as a multi-purpose building that also functions as a tornado shelter. C402.4.2 currently has minimum skylight fenestration requirements for “gymnasium/exercise center” spaces (and other types of spaces). This is generally good because there is value in having skylight fenestration in these spaces. However, the special case when a gymnasium is also used as a storm shelter warrants an exception to C402.4.2. There is an elevated life-safety concern associated with storm shelters and any skylights must meet strict missile impact testing and pressure requirements or be protected upon activation of the shelter with shutters. Building officials have requested this change to clarify that the intent of C402.4.2 was not to require skylights in storm shelters.

**Cost Impact:** The code change proposal will decrease the cost of construction if skylights are not required, then the number of openings requiring protectives will be decreased.

**Analysis:** The referenced standard, ICC 500-2014, is currently referenced in other 2018 I-codes.

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C402.4.3 Maximum $U$-factor and SHGC. The maximum $U$-factor and solar heat gain coefficient (SHGC) for fenestration shall be as specified in Table C402.4.
The window projection factor shall be determined in accordance with Equation 4-5.

\[
PF = \frac{A}{B}
\]
(Equation 4-5)
where:

\(PF\) = Projection factor (decimal).

\(A\) = Distance measured horizontally from the farthest continuous extremity of any overhang, eave or permanently attached shading device to the vertical surface of the glazing.

\(B\) = Distance measured vertically from the bottom of the glazing to the underside of the overhang, eave or permanently attached shading device.

Where different windows or glass doors have different $PF$ values, they shall each be evaluated separately.

**Exception:** The maximum $U$-factor and solar heat gain coefficient (SHGC) for fenestration shall not be required in storm shelters complying with ICC 500.

Add new standard(s) as follows:

**ICC 500: ICC/NSSA Standard for the Design and Construction of Storm Shelters**

Proposal # 4851

International Code Council, Inc.
500 New Jersey Avenue NW 6th Floor
Washington DC 20001

IC9E93-19 Part I
CE93-19 Part II
IECC: R402.5 (IRC N1102.5), ICC Chapter 06

Proponent: Benchmark Harris, representing National Storm Shelter Association (bharris@huckabee-inc.com)

2018 International Energy Conservation Code

Revise as follows:

R402.5 (IRC N1102.5) Maximum fenestration $U$-factor and SHGC (Mandatory). The area-weighted average maximum fenestration $U$-factor permitted using tradeoffs from Section R402.1.5 or R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 in Climate Zones 1 through 3 shall be 0.50.

Exception: The maximum $U$-factor and solar heat gain coefficient (SHGC) for fenestration shall not be required in storm shelters complying with ICC 500.

Add new standard(s) as follows:

ICCID 500: ICC/NSSA Standard for the Design and Construction of Storm Shelters

Reason: This proposal is submitted by the National Storm Shelter Association (NSSA) and the ICC 500 Storm Shelter Standard Development committee.

The ICC 500 Standards Development committee is responsible for the development of the ICC/NSSA Standard for the Design and Construction of Storm Shelters. The committee is currently working on the development of the 2020 edition. In 2017 the ICC 500 committee held 7 open conference calls. In addition, there were numerous Working Group meetings and conference calls, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm.

NSSA was responsible for the development of the original standard for storm shelters in 2001, which ICC 500 replaced through an agreement between ICC and NSSA. Representing General, User and Producer interest categories, NSSA is a technical organization that is committed to promoting consistent quality in both residential and community storm shelters.

Storm windows have a limited availability with the $U$ values required in Section R402.3 and R402.5. There is an elevated life-safety concern associated with storm shelters and any window must meet strict missile impact testing and pressure requirements or be protected upon activation of the shelter with shutters.

Cost Impact: The code change proposal will decrease the cost of construction
This modification will increase design options.

Analysis: The referenced standard, ICC 500-2014, is currently referenced in other 2018 I-codes.

Proposal # 5752
Add new text as follows:

**C402.4.3.4 Automated Dynamic Shades** Where interior or exterior shades, blinds, louvers, or drapes are used to improve the overall SHGC of the fenestration system, the combined performance calculated in accordance with Appendix B of AERC 1 and multiplied by 1.1 shall be permitted to satisfy the SHGC requirements found in Table C402.4 provided the shading device complies with all of the following:

1. The shading device is permanently attached.

2. The shading device is automatically controlled and capable of automatically modulating the amount of solar gain and light transmitted into the space in multiple steps in response to daylight levels or solar intensity.

3. The shading device is capable of providing not less than 90 percent coverage of the fenestration in the closed position.

4. Any manual control of the shading device shall not override automatic operation for longer than 4 hours per actuation.

Add new standard(s) as follows:

**Reason:** Window and skylight shading systems can provide significant improvement in SHGC of fenestration systems. The only way to guarantee that these systems block solar heat gain when needed is through automatic control based on light or heat at the façade. There already is an allowance for dynamic glazing (C402.4.3.3 Dynamic Glazing) to be allowed to help comply with SHGC. This proposal is similar but for permanent automated window shading devices. These automated shading devices are typically permanently attached to the interior or exterior of the wall or roof, are hardwired into the building and are as permanent as any luminaire.

The combined SHGC for the combination of the selected shading system with any window or skylight system is
readily available from the shading manufacturers or computed in free validated software such as WINDOW from Lawrence Berkeley National Laboratory.

There are industry standards that are used to measure the combined SHGC performance of windows with shading devices. Performance tests for Solar Heat Gain Coefficient SHGC (G-Value), Solar Transmittance (Ts), Solar Reflectance (Rs), Solar Absorptance (As), Visible Light Transmission VLT (Tv) can be conducted in accordance with EN 14501:2005, ASTM E891, and ASTM E903-96. Glass performance tests can be conducted using the Lawrence Berkeley National Laboratory Window NFRC certified software.

An example study showing how automated shading systems with high solar reflectance fabrics (example from Mermet: http://www.mermetusa.com/transparent/t-screen-with-koolblack-3-5.html) save significant cooling energy can be found at: http://performanceshadingadvisor.com/#thermalmanagement

In addition to solar heat gain improvement, this technology inherently saves other energy. When the shade is open, there will be more savings on the electric lighting side due to daylight dimming. Automation closes the shade when there is glare or increased solar energy, but opens the shade to allow more natural light when glare or solar heat gain is not a problem.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal does not require use of dynamic shading; it just allows combined SHGC to be used if a project is already using dynamic shades.

**Analysis:** A review of the standard proposed for inclusion in the code, AERC 1, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Energy Conservation Code

Revise as follows:

C403.2.2 Ventilation (Mandatory). Ventilation, either natural or mechanical, shall be provided in accordance with the commercial building provisions of Chapter 4 of the International Mechanical Code. Where mechanical ventilation is provided, the system shall provide the capability to reduce the outdoor air supply to the minimum required by Chapter 4 of the International Mechanical Code.

Reason: Section C403.2.2 "Ventilation" of the Energy Code references Chapter 4 of the Mechanical Code. However, Section 401.2 of the Mechanical Code includes a cross reference to a residential provision of the Energy Code: R402.4.1.2 pertaining to dwelling units. This may inadvertently and erroneously lead code users to believe that dwelling units in a commercial building, such as a multi-family building more than three stories in height, can be regulated by the residential provisions of the Energy Code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is simply a clarification of an existing code provision and does not carry a cost implication.
CE96-19
IECC: C202 (New), C402.5, C402.5.1, C402.5.1.2, C402.5.1.2.3 (New)

Proponent: Gayathri Vijayakumar, representing Steven Winter Associates, Inc. (gayathri@swinter.com); Robert Schwarz, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

TESTING UNIT ENCLOSURE AREA. The area sum of all the boundary surfaces that define the dwelling unit, sleeping unit, or occupiable conditioned space including top/ceiling, bottom/floor, and all side walls. This does not include interior partition walls within the dwelling unit, sleeping unit, or occupiable conditioned space. Wall height shall be measured from the finished floor of the conditioned space to the finished floor or roof/ceiling air barrier above.

Revise as follows:

C402.5 Air leakage—thermal envelope (Mandatory). The building thermal envelope of buildings shall comply with Sections C402.5.1 through C402.5.8, or the building thermal envelope shall be tested in accordance with ASTM E 779 at a pressure differential of 0.3 inch water gauge (75 Pa) or an equivalent method approved by the code official and deemed to comply with the provisions of this section when the tested air leakage rate of the building thermal envelope is not greater than 0.40 cfm/ft² (2.0 L/s • m²). Where compliance is based on such testing, the building shall also comply with Sections C402.5.5, C402.5.6 and C402.5.7.

C402.5.1 Air barriers. A continuous air barrier shall be provided throughout the building thermal envelope. The continuous air barriers shall be permitted to be located on the inside or outside of the building thermal envelope, located within the assemblies composing the building thermal envelope, or any combination thereof. The air barrier shall comply with Sections C402.5.1.1 and C402.5.1.2.

Exception: Air barriers are not required in buildings located in Climate Zone 2B.

C402.5.1.1 Air barrier construction. The continuous air barrier shall be constructed to comply with the following:

1. The air barrier shall be continuous for all assemblies that are the thermal envelope of the building and across the joints and assemblies.
2. Air barrier joints and seams shall be sealed, including sealing transitions in places and changes in materials. The joints and seals shall be securely installed in or on the joint for its entire length so as not to dislodge, loosen or otherwise impair its ability to resist positive and negative pressure from wind, stack effect and mechanical ventilation.
3. Penetrations of the air barrier shall be caulked, gasketed or otherwise sealed in a manner compatible with the construction materials and location. Sealing shall allow for expansion, contraction and mechanical vibration. Joints and seams associated with penetrations shall be sealed in the same manner or taped. Sealing materials shall be securely installed around the penetration so as not to dislodge, loosen or otherwise impair the penetrations’ ability to resist positive and negative pressure from wind, stack effect and mechanical ventilation. Sealing of concealed fire sprinklers, where required, shall be in a manner that is recommended by the
CaULKING or other adhesive sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

4. Recessed lighting fixtures shall comply with Section C402.5.8. Where similar objects are installed that penetrate the air barrier, provisions shall be made to maintain the integrity of the air barrier.

C402.5.1.2 Air barrier compliance options. A continuous air barrier for the opaque building envelope shall comply with the following:

1. Buildings or portions of buildings including Group R and Group I occupancy shall meet the provisions of Section C402.5.1.2.3.
   **Exception:** Buildings in Climate Zones 2B, 3C, and 5C.

2. Buildings or portions of buildings including Group R and Group I occupancy in Climate Zones 3C and 5C shall meet the provisions of Section C402.5.1.2.1 or C402.5.1.2.2.

3. Buildings or portions of buildings other than Group R and Group I occupancy shall meet the provisions of Section C402.5.1.2.1 or C402.5.1.2.2.

C402.5.1.2.1 Materials. Materials with an air permeability not greater than 0.004 cfm/ft² (0.02 L/s • m²) under a pressure differential of 0.3 inch water gauge (75 Pa) when tested in accordance with ASTM E2178 shall comply with this section. Materials in Items 1 through 16 shall be deemed to comply with this section, provided that joints are sealed and materials are installed as air barriers in accordance with the manufacturer’s instructions.

1. Plywood with a thickness of not less than 3/8 inch (10 mm).
2. Oriented strand board having a thickness of not less than 3/8 inch (10 mm).
3. Extruded polystyrene insulation board having a thickness of not less than 1/2 inch (12.7 mm).
4. Foil-back polyisocyanurate insulation board having a thickness of not less than 1/2 inch (12.7 mm).
5. Closed-cell spray foam having a minimum density of 1.5pcf (2.4 kg/m³) and having a thickness of not less than 1 1/2 inches (38 mm).
6. Open-cell spray foam with a density between 0.4 and 1.5pcf (0.6 and 2.4 kg/m³) and having a thickness of not less than 4.5 inches (113 mm).
7. Exterior or interior gypsum board having a thickness of not less than 1/2 inch (12.7 mm).
8. Cement board having a thickness of not less than 1/2 inch (12.7 mm).
10. Modified bituminous roof membrane.
12. A Portland cement/sand parge, or gypsum plaster having a thickness of not less than 5/8 inch (15.9 mm).
15. Sheet steel or aluminum.
16. Solid or hollow masonry constructed of clay or shale masonry units.

C402.5.1.2.2 Assemblies. Assemblies of materials and components with an average air leakage not greater than 0.04 cfm/ft² (0.2 L/s • m²) under a pressure differential of 0.3 inch of water gauge (w.g.)(75 Pa) when tested in accordance with ASTM E2357, ASTM E1677 or ASTM E283 shall comply with this section. Assemblies listed in Items 1 through 3 shall be deemed to comply, provided that joints are sealed and the requirements of Section C402.5.1.1 are met.

1. Concrete masonry walls coated with either one application of block filler or two applications of a
paint or sealer coating.
2. Masonry walls constructed of clay or shale masonry units with a nominal width of 4 inches (102 mm) or more.
3. A Portland cement/sand parge, stucco or plaster not less than 1/2 inch (12.7 mm) in thickness.

Add new text as follows:

C402.5.1.2.3 Dwelling and sleeping unit enclosure testing The building thermal envelope shall be tested in accordance with ASTM E 779, ANSI/RESNET/ICC 380, ASTM E1827 or an equivalent method approved by the code official. The measured air leakage shall not exceed 0.30 cfm/ft² (1.5 L/s · m²) of the testing unit enclosure area at a pressure differential of 0.2 inch water gauge (50 Pa). Where multiple dwelling units or sleeping units or other occupiable conditioned spaces are contained within one building thermal envelope, each unit shall be considered an individual testing unit and the building air leakage shall be the weighted average of all testing unit results, weighted by each testing unit's testing unit enclosure area. Units shall be tested separately with an unguarded blower door test as follows:

1. Where buildings have fewer than eight testing units, each testing unit shall be tested.
2. For buildings with eight or more testing units the greater of seven units or 20 percent of the testing units in the building shall be tested including a top floor unit, a ground floor unit, and a unit with the largest testing unit enclosure area. Where any tested unit exceeds the maximum air leakage rate, an additional 20 percent of units shall be tested, including a mixture of testing unit types and locations.

Reason: Air leakage can be a significant source of energy waste in buildings, contributing to higher heating and cooling costs for building owners and occupants, and increasing risk related to comfort and durability. Air tightness testing can result in more attention to air barrier sealing and significantly reduced building leakage. Currently, the residential energy code requires air tightness testing for residential buildings three stories and less in height to ensure proper tightness and a controlled indoor environment. However, in the commercial energy code there is no testing requirement for residential buildings four stories or more in height (e.g., apartments, dormitories, hotel guest rooms). Industry standards affecting these buildings have historically relied upon visual verification, as well as material and assembly requirements. Providing adequate control over air leakage can also allow many benefits, including reduced HVAC equipment sizing, better building pressurization, and energy savings due to reduced heating and cooling of infiltrated outside air. In moist climates, ensuring lower leakage through testing can also result in better humidity control and reduced risk of durability issues. Air barrier testing saves energy by reducing infiltration of outside air into and out of the building. Most of the time, outside air is hotter or colder than the comfort temperature being maintained in the residence by the heating and cooling systems. Therefore, reducing the infiltration will reduce energy use for heating and cooling. This proposal would require that blower door testing be applied to a sample of units or occupiable spaces in a multiple unit residential construction project. The equipment and staff required are the same as are needed in current air leakage testing required under the residential energy code.

Why is building leakage testing superior to other approaches?

While it is important that the materials and assemblies have limited leakage, specification by individual materials and assemblies does not necessarily equate to an air-tight building. Recent research (Wiss 2014) shows that 40% of buildings constructed without an envelope consultant have air leakage exceeding the current optional test standard of 0.40 cfm/ft² at 75 Pa, while buildings with envelope consultants had leakage below 0.25 cfm/ft² at 75 Pa. Requiring testing will ensure that the goal of this section of the code—limiting unintended air infiltration in buildings—is achieved.

What strategies are considered to minimize compliance burdens in the field?

To manage testing cost, a testing approach is proposed that requires only 20% of the units (with a seven-unit
minimum) to be tested in the building. The testing method is also an unguarded test of individual units that reduces cost significantly compared to whole building testing or guarded unit testing. To motivate high-quality air sealing, additional testing of an additional 20% of the units would be required if any unit exceeds the leakage limit. Then the weighted average of tested units is used for comparison to the required leakage limit. While the testing requirement is slightly less stringent than the residential code, it matches current optional commercial requirements and is an improvement over the current condition of no testing requirements in the commercial code. It also provides a more reasonable target than air changes per hour for these units, which are typically smaller and have less total leakage than detached residences.

Are there existing codes and standards that require similar testing measures?

This proposal is similar to the residential air leakage provisions in the 2018 IECC in that it also requires the use of ASTM E 779. The proposal is similar to air leakage testing that is required by the State of Washington and City of Seattle commercial building energy codes as well as procedures followed by the U.S. Department of Defense for testing of commercial buildings. The City of Seattle requirements have been in place since 2009 and hundreds of commercial buildings have been tested under that code, including many large buildings. Additionally, thousands of dwelling units have successfully been tested and achieved this metric through the USGBC's LEED for Homes Multifamily Mid-Rise program and the EPA's ENERGY STAR Multifamily High Rise program. It will also be a required test in ASHRAE 62.2-2019.

Cost Impact: The code change proposal will increase the cost of construction

PNPL performed a cost-effectiveness analysis to identify the net impacts associated with the proposal using the established DOE methodology (Hart and Liu 2015). Results of the cost-effectiveness analysis indicate that the average savings-to-investment ratio (SIR) and simple payback (SPP) for unguarded dwelling unit testing with a limit of 0.30 cfm/ft² (1.5 L/s · m²) at a pressure differential of 0.2 inch water gauge (50 Pa) in mid-rise apartment buildings were:

- SIR: 7.8; cost-effective if greater than 1.0
- SPP: 5.3 years; cost-effective if less than 40 year life

A measure is cost-effective when the SIR is greater than 1.0, indicating that the present value of savings is greater than the incremental cost. The cost for individual unguarded unit testing is expected to be significantly lower than the cost for whole building testing, especially with the sampling protocol provided. Results of the cost-effectiveness analysis were taken into account when developing this proposal (i.e., the recommended language only targets building types and climate zones where the testing requirement was determined to be cost-effective).

For buildings already conducting whole-building testing as their compliance option, this may decrease the cost of construction. For buildings not conducting testing, this is an increase in costs to perform the tests. This
proposal however does not require more than what is currently required in the residential IECC for similar types of commercial buildings 3 stories and lower.
Proponent: Eric Makela, New Buildings Institute, representing Northwest Energy Codes Group (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

C402.5 Air leakage—thermal envelope (Mandatory). The building thermal envelope of buildings shall comply with Sections C402.5.1 through C402.5.8, or the building thermal envelope shall be tested in accordance with ASTM E 779 at a pressure differential of 0.3 inch water gauge (75 Pa) or an equivalent method approved by the code official and deemed to comply with the provisions of this section when the tested air leakage rate of the building thermal envelope is not greater than 0.40 cfm/ft² (2.0 L/s • m²). Where compliance is based on such testing, the building shall also comply with Sections C402.5.5, C402.5.6 and C402.5.7.

C402.5.1 Air barriers. A continuous air barrier shall be provided throughout the building thermal envelope. The air barriers shall be permitted to be located on the inside or outside of the building thermal envelope, located within the assemblies composing the building thermal envelope, or any combination thereof. The air barrier shall comply with Sections C402.5.1.1 and C402.5.1.2.

Exception: Air barriers are not required in buildings located in Climate Zone 2B.

C402.5.1.2 Air barrier compliance options: compliance. A continuous air barrier for the opaque building envelope shall comply with the following:

1. Buildings or portions of buildings including group R and group I occupancy shall meet the provisions of Section C402.5.1.2.1 or C402.5.1.2.2.
2. Buildings or portions of buildings of other than group R and group I occupancy shall meet the provisions of Section C402.5.1.2.3.

Exceptions:

1. Buildings in Climate Zones 2B, 3B, 3C, and 5C.
2. Buildings larger than 5000 square feet floor area in Climate Zones 0B, 1, 2A, 4B, and 4C.
3. Buildings between 5000 and 50,000 square feet floor area in Climate Zones 0A, 3A and 5B.

3. Buildings or portions of buildings other than group R and group I occupancy that do not complete air barrier testing shall meet the provisions of Section C402.5.1.2.1 or C402.5.1.2.2.

Add new text as follows:

C402.5.1.2.3 Non-residential building thermal envelope testing. The building thermal envelope shall be tested in accordance with ASTM E 779 or an equivalent method approved by the code official. The measured air leakage shall not exceed 0.40 cfm/ft² (2.0 L/s • m²) of the building thermal envelope area at a pressure differential of 0.3 inch water gauge (75 Pa). Alternatively, portions of the building shall be tested and the measured air leakages shall be area-weighted by the surface areas of the building envelope in each portion. The weighted average test results shall not exceed the whole building leakage limit. In the alternative approach, the following portions of the building shall be tested:
1. The entire envelope area of all stories that have any spaces directly under a roof,
2. The entire envelope area of all stories that have a building entrance, exposed floor, or loading dock, or are below grade, and
3. Representative above-grade sections of the building totaling at least 25 percent of the wall area enclosing the remaining conditioned space.

**Exception:** Where the measured air leakage rate exceeds 0.40 cfm/ft\(^2\) (2.0 L/s•m\(^2\)) but does not exceed 0.60 cfm/ft\(^2\) (3.0 L/s•m\(^2\)), a diagnostic evaluation using smoke tracer or infra-red imaging shall be conducted while the building is pressurized along with a visual inspection of the air barrier. Any leaks noted shall be sealed where such sealing can be made without destruction of existing building components. An additional report identifying the corrective actions taken to seal leaks shall be submitted to the code official and the building owner, and shall be deemed to comply with satisfy the requirements of this section.

**Reason:** Air leakage can be a significant source of energy waste in buildings, contributing to higher heating and cooling costs for building owners and occupants, and increasing risk related to comfort and durability. Air tightness testing can result in more attention to envelope assembly air barrier sealing and significantly reduced building leakage. Currently Section C402.5 Air Leakage – thermal envelope, allows air tightness testing as an alternative to meeting material or assembly selection and installation method requirements to ensure proper tightness and a controlled indoor environment. Adequate control over air leakage can provide many benefits, including reduced HVAC equipment sizing, better building pressurization, and energy savings due to reduced heating and cooling of infiltrated outside air. In moist climates, ensuring lower air leakage through whole-building testing can also result in better humidity control and reduced risk of durability issues.

While it is important that the materials and assemblies have limited leakage, that alone does not guarantee a low leakage building. Recent research (Wiss 2014) shows that 40% of buildings constructed without an envelope consultant have air leakage exceeding the currently optional test standard requirements, while buildings with envelope consultants all had leakage below 0.25 cfm/ft\(^2\). Testing is the most reliable means of ensuring that the intent of this code section—limiting unintended energy waste in buildings due to air infiltration—will be achieved.

The measure retains the current IECC optional compliance path test limit of 0.40 cfm/ft\(^2\) at 75 Pa. Since mandatory—rather than optional—testing would be a new requirement, it is appropriate to retain the current and higher limit of 0.4 cfm/ft\(^2\) for improved building industry acceptance. Durston and Heron’s review (2012) of the more stringent requirements by the U.S. Department of Defense (DOD) shows that without testing, the range of building leakage can exceed the requirement by more than double (0.9 cfm/ft\(^2\)). However, with testing included as part of the construction process, the average leakage of buildings was determined to be well below the 0.4 cfm/ft\(^2\) limit. Therefore, based on the DOD findings, the test limit of 0.40 cfm/ft\(^2\) is considered a realistic and achievable goal. In addition, the target is well established in the IECC, and aligns with similar optional requirements contained in Standard 90.1.

**Intent of the Code Change Proposal**

This code change proposal will require

- The leakage testing thresholds are the same as current optional testing thresholds.
- Proposed requirements for testing vary by climate zone and building size and are based on industry-accepted cost-effectiveness analysis methods.
- As outlined in the optional compliance path, portions of buildings could be tested on a sampling basis.
- Commercial buildings under 5000 square feet can be tested using residential methods, technicians, and
equipment with the maximum leakage rate set at 0.30 cfm/ft\(^2\) (1.5 L/s · m\(^2\)) at 0.2 in. w.g. (50 Pa). This testing pressure differential is common for residential testing, and is equivalent to a leakage rate of 0.40 cfm/ft\(^2\) (1.5 L/s · m\(^2\)) at 0.3 in. w.g. (75 Pa), the current alternative commercial test limit. Yet, implementing the residential procedure can dramatically reduce testing costs for these smaller buildings.

· Since this would be a new requirement, a backup exception is provided so that if a building fails the 0.40 cfm/ft\(^2\) test, the building can still pass the requirement as long as the tested value is below 0.60 cfm/ft\(^2\) and additional diagnostics are performed.

Climate Zones 0A and 0B are included in the code change proposal assuming that a code change proposal submitted by SEHPCAC to update the climate zones is submitted and approved. These climate zone designations can be removed from the proposal with no impact if the climate zones are not updated.

**What strategies are considered to minimize compliance burdens in the field?**

Three specific strategies are applied to minimize the impact of testing on building project costs:

· Testing is only required for certain building types and climate zones where analysis indicates it is cost-effective and the savings justifies the cost. Based on that analysis, size thresholds by climate zone are provided for non-residential buildings.

· It is also prudent to provide some flexibility in the test standard to allow for building industry acceptance and a transition to meeting a fixed testing requirement. Specifically, when the building envelope is complete and testing occurs, access to the air barrier for repairs is difficult. Thus, an exception is included that allows the tested leakage rate to be no more than 0.6 cfm/ft\(^2\) as long as specific remediation efforts are made. This exception is meant to provide a modest relaxation of the requirement, but only if significant corrective actions are taken that may reduce the air leakage.

· As an additional strategy, the measure allows representative portions or a sample of spaces in the building to be tested instead of the whole building. This alternative supports more economical testing of large buildings, which can help reduce the compliance burden and is consistent with similar requirements in ASHRAE 90.1-2016.

**Existing Codes and Standards that Require Similar Testing Measures**

The measure is consistent with air leakage testing requirements and thresholds required by the State of Washington and City of Seattle commercial building energy codes (SDCI Community Engagement 2012), as well as procedures followed by the DOD for testing of commercial buildings referenced above. The City of Seattle requirements have been in place since 2009, and hundreds of commercial buildings have been tested under that code, including many large buildings. The proposed measure is less stringent than the current DOD requirements (0.25 cfm/ft\(^2\)), and case studies (Durston and Heron 2012) have shown that much lower leakage levels—in the range of 0.15 cfm/ft\(^2\)—can be achieved.

**Energy Savings**

An analysis of energy impact shows that annual energy savings from air barrier improvement resulting from testing due to the measure ranges from $5.07 to $71.88 per thousand square feet of floor area in offices in climate zones where testing is recommended. More details are found in the cost-effectiveness analysis referenced in the Appendix.
**Cost-effectiveness:** Pacific Northwest National Laboratory performed a cost-effectiveness analysis using the established DOE methodology (Hart and Liu 2015). Results of the analysis indicate that the average savings-to-investment ratio (SIR) and simple payback period (SPP) for commercial building testing with a limit of 0.40 cfm/ft² (1.5 L/s · m²) at a pressure differential of 0.3 inch w.g. (50 Pa) in office buildings vary by size, as shown in the table below.

<table>
<thead>
<tr>
<th>Building size range, floor area square feet</th>
<th>&lt;5000</th>
<th>5000 to 50,000</th>
<th>&gt;50,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average SIR</td>
<td>7.3</td>
<td>2.2</td>
<td>3.2</td>
</tr>
<tr>
<td>Average SPP (years)</td>
<td>7.1</td>
<td>13.1</td>
<td>10.2</td>
</tr>
</tbody>
</table>

A measure is cost-effective when the SIR is greater than 1.0, indicating that the present value of savings is greater than the incremental cost. Under ASHRAE 90.1 criteria, cost-effectiveness is proven when the simple payback is shorter than the scalar threshold of 22.2 years. Based on the cost-effectiveness analysis results, air barrier testing is specified for buildings that have both an SIR greater than 1 and a simple payback that is less than the 90.1 scalar threshold based on climate zone and building size.

As a result of breaks in cost assumptions, most climate zones qualify for testing for buildings below 5000 square feet, with fewer climate zones requiring testing for buildings larger than 50,000 square feet, and the fewest climate zones requiring testing for buildings between 5000 and 50,000 square feet.

**Bibliography:**

TechBrief-ComBldgAirLeakageTesting_PNNL-28367

Durston JL and M Heron. 2012. **Summary and Analysis of Large Building Air Leakage Testing for the U.S. Department of Defense.** Atlanta, GA.

**Background References**

**Cost Impact:** The code change proposal will increase the cost of construction
This measure will increase the cost of construction of new commercial buildings as whole building air leakage testing will be required except for primarily residential buildings (Group R and I building occupancies). Based on a survey of professional commercial building air barrier testing companies, it was determined that the cost of air
leakage testing fell into three ranges:

- $350 or $0.12 to $0.07 per square foot for buildings up to 5000 square feet
- $0.50 to $0.15 per square foot for buildings between 5000 and 50,000 square feet
- $0.15 to $0.09 per square foot for buildings between 50,000 and 100,000 square feet, with decreasing costs for larger buildings.

As demand for air leakage testing in commercial buildings increases, more companies will enter the market to provide these services. Therefore, a gradual decrease in cost is expected as more companies are available to do the testing.
CE98-19

IECC: C402.5, Chapter 6CE (New)

Proponent: Theresa Weston, representing Air Barrier Association of America (ABAA)  
(theresa.a.weston@dupont.com)

2018 International Energy Conservation Code

Revise as follows:

**C402.5 Air leakage—thermal envelope (Mandatory).** The *thermal envelope* of buildings shall comply with Sections C402.5.1 through C402.5.8, or the building *thermal envelope* shall be tested in accordance with ASTM E779 at a pressure differential of 0.3 inch water gauge (75 Pa), ASTM E3158 or an equivalent method approved by the code official and deemed to comply with the provisions of this section when the tested air leakage rate of the building thermal envelope is not greater than 0.40 cfm/ft² (2.0 L/s • m²). Where compliance is based on such testing, the building shall also comply with Sections C402.5.5, C402.5.6 and C402.5.7.

Add new standard(s) as follows:

**ASTM**

ASTM E3158-18: **Test Method for Measuring the Air Leakage Rate of a Large or Multizone Building**

**Reason:** This proposal adds an option for the test method used to test a building’s air leakage. The method was developed with significant input for industry testing professionals and will be especially beneficial for large and multi-zone buildings.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. No cost effect as it does not change requirements only provides more options to the testing details.

**Analysis:** A review of the standard proposed for inclusion in the code, ASTM E3158, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
Proponent: Eric Makela, New Buildings Institute, representing Northwest Energy Codes Group (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

C103.2 Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include, but are not limited to, the following as applicable:

1. Insulation materials and their $R$-values.
2. Fenestration $U$-factors and solar heat gain coefficients (SHGCs).
3. Area-weighted $U$-factor and solar heat gain coefficient (SHGC) calculations.
4. Mechanical system design criteria.
5. Mechanical and service water heating systems and equipment types, sizes and efficiencies.
7. Equipment and system controls.
8. Fan motor horsepower (hp) and controls.
9. Duct sealing, duct and pipe insulation and location.
10. Lighting fixture schedule with wattage and control narrative.
11. Location of daylight zones on floor plans.
12. Air sealing details, barrier and air sealing details, including the location of the air barrier.

C402.5.1 Air barriers. A continuous air barrier shall be provided throughout the building thermal envelope. The air barriers shall be permitted to be located on the inside or outside of the building envelope, located within the assemblies composing the envelope, or any combination thereof. The air barrier shall comply with Sections C402.5.1.1, C402.5.1.2 and C402.5.1.3.

Exception: Air barriers are not required in buildings located in Climate Zone 2B.

Add new text as follows:

C402.5.1.3 Building envelope performance verification. The installation of the continuous air barrier shall be verified by a registered design professional or approved agency in accordance with the following:

1. A review of the construction documents and other supporting data shall be conducted to assess compliance with the requirements in Sections C402.5.1.
2. Inspection of continuous air barrier components and assemblies shall be conducted during construction while the air barrier is still accessible for inspection and repair to verify compliance with the requirements of Sections C402.5.1.1 and C402.5.1.
3. A final commissioning report shall be completed by the registered design professional or approved agency and provided to the building owner or owner’s authorized agent and the code official. The report shall identify deficiencies found during the review of the construction documents and inspection and details of corrective measures used.

Reason: The testing path for infiltration in the IECC requires a leakage rate of 0.40 CFM/sf @ 75PA. However, according to “Achieving the 30% Goal: Energy and Cost Savings Analysis of ASHRAE Standard 90.1-2010”
prepared by the Pacific Northwest National Lab, the prescriptive air barrier requirements currently used in the IECC only achieve 1.0 CFM/sf @ 75Pa. The prescriptive path is therefore not achieving the level of performance achieved by the testing path. The code requires that air barrier materials meet 0.40 CFM/sf @ 75Pa, so the issue must be with installation and not the materials themselves. This proposal narrows that gap by requiring verification of the air barrier during construction and reporting back to the owner and code official in a manner similar to existing acceptance testing requirements, thereby ensuring better air barrier installation without actually requiring testing.

The proposal includes a sequence of requirements to ensure both effectiveness, ease of implementation and ease of enforcement. Key among these is a requirement that the inspection occur while remediation of errors can still be remedied. Submission of the report to the code official and the owner will ensure that the process has been followed.

The proposal also modifies the charging language in C402.5 and the construction documentation requirements in C103 to enable the new requirements.

According to Evan Mills, PhD, a researcher at Lawrence Berkeley National Laboratory, savings associated with using BECx from both maintenance and energy savings average about 16% for existing buildings and 13% for new construction (“Calculating the ROI of building enclosure commissioning.” Building Design + Construction. June 28, 2013.)

**Cost Impact:** The code change proposal will increase the cost of construction
Evan Mills, PhD, a researcher at Lawrence Berkeley National Laboratory studied the benefits of BECx, noting that commissioning only costs about $1.16/sf for new construction and $0.30/sf for existing buildings on average, with a payback period of as little as 14 months.
CE100-19

IECC: C402.5.1.2

Proponent: Laverne Dalgleish, Building Professionals, representing Air Barrier Association of America (ldalgleish@airbarrier.org)

2018 International Energy Conservation Code

Revise as follows:

C402.5.1.2 Air barrier compliance options. A continuous air barrier for the opaque building envelope shall comply with Section C402.5.1.2.1 or and C402.5.1.2.2.

Reason: The option of simply conducting a air leakage rate test on a one square meter (approximatery 39 inches square) of material does not mean that using the material in a building that does not have excessive air leakage. The material needs to be put together into an air barrier assembly with the use of air barrier accessories. These accessories include but not limited to tapes, caulks, strips, sheets, etc. By putting an air barrier assembly together and then testing the air leakage rate of the assembly, will provide the building contractor with guidance with how the material needs to be installed on the building and what air barrier accessories are required to seal the pieces of materials together and to the terminations and penetrations.

There are many materials that will meet the requirements of this building code when tested as a material, but will not reduce the air leakage rate of the whole building. Materials like Jello and peanut butter to very rigid materials like ceramics will not perform when subjected to the loads imposed on the material installed in a building. Other materials will simply not stay in place after installation.

Please consider the Air Permeance Comparison Report (10-06-M0027) for Building Professionals at the ABAA website: http://www.airbarrier.org/technical-information/abaa-articles-standards/

An example would be a self-adhered material that does not stick to the substrate after installation.

Cost Impact: The code change proposal will increase the cost of construction

There is no increase to the site construction cost. For many manufacturers who have already conducted an air barrier assembly air leakage test, there is no additional costs to them. If a manufacturer has not conducted an air barrier assembly air leakage test on their materials, they would have to conduct this test. The test can run from $5,000 to $20,000 for the test, depending on how complex their installation instructions are.

The test is an initial type test which means that the manufacturer conducts the test once for the sales life of the material. An air barrier material can be produced with millions of dollars of sales each year and some material have been on the market for over ten years.

Proposal # 5646
IECC: C402.5.1.2.2, ASTM Chapter 06 (New)

Proponent: Laverne Dalgleish, representing Air Barrier Association of America (ldalgleish@airbarrier.org)

2018 International Energy Conservation Code

Revise as follows:

C402.5.1.2.2 Assemblies. Assemblies of materials and components with an average air leakage not greater than 0.04 cfm/ft² (0.2 L/s • m²) under a pressure differential of 0.3 inch of water gauge (w.g.) (75 Pa) when tested in accordance with ASTM E2357, or ASTM E1677 for walls, ASTM D8052 for low slope roofs or ASTM E283 for fenestrations shall comply with this section. Assemblies listed in Items 1 through 3 shall be deemed to comply, provided that joints between materials, penetrations and terminations are sealed and the requirements of Section C402.5.1.1 are met.

1. Concrete masonry walls coated with either one application of block filler or two applications of a paint or sealer coating.
2. Masonry walls constructed of clay or shale masonry units with a nominal width of 4 inches (102 mm) or more.
3. A Portland cement/sand parge, stucco or plaster not less than ½ inch (12.7 mm) in thickness.

Add new text as follows:

Reason: The air barrier industry uses the terms "air barrier material" to be combined with an "air barrier accessory" to form an "air barrier assembly". The term "air barrier component" is used to refer to pre-manufactured elements like doors, windows and shylights, etc. where a separate test is used to determine their air leakage rate. The test method to determine the air leakage rate of a low sloped roof should be referenced as the existing test methods are not appropriate to test low sloped roofs.

It is important to identify the building assembly that the test method is appropriate for, otherwise people will use the wrong test method for testing their building assembly.

The addition of penetrations and terminations to the areas where joints need to be sealed is to bring to the attention of the reader that all joints need to be sealed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal simply clarifies the intent of this part of the building code.

Proposal # 5657

CE101-19
Proponent: Darren Meyers, P.E., IECC_LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

C402.5.1.2.1 Materials. Materials with an air permeability not greater than 0.004 cfm/ft² (0.02 L/s • m²) under a pressure differential of 0.3 inch water gauge (75 Pa) when tested in accordance with ASTM E2178 shall comply with this section. Materials in Items 1 through 16 shall be deemed to comply with this section, provided that joints are sealed and materials are installed as air barriers in accordance with the manufacturer’s instructions.

1. Plywood with a thickness of not less than 3/8 inch (10 mm).
2. Oriented strand board having a thickness of not less than 3/8 inch (10 mm).
3. Extruded polystyrene insulation board having a thickness of not less than 1/2 inch (12.7 mm).
4. Foil-back polyisocyanurate insulation board having a thickness of not less than 1/2 inch (12.7 mm).
5. Closed-cell spray foam having a minimum density of 1.5 pcf (2.4 kg/m³) and having a thickness of not less than 1 1/2 inches (38 mm).
6. Open-cell spray foam with a density between 0.4 and 1.5 pcf (0.6 and 2.4 kg/m³) and having a thickness of not less than 4.5 inches (113 mm).
7. Exterior or interior gypsum board having a thickness of not less than 1/2 inch (12.7 mm).
8. Cement board having a thickness of not less than 1/2 inch (12.7 mm).
10. Modified bituminous roof membrane.
12. A Portland cement/sand parge, or gypsum plaster having a thickness of not less than 5/8 inch (15.9 mm).
15. Sheet steel or aluminum.
16. Solid or hollow masonry constructed of clay or shale masonry units.

Reason: The NRCA’s intent here is to provide clarity consistent with ASHRAE Standard 90.1-2013, Addendum ‘ay’, ASHRAE Standard 90.1-2016, Section 5.4.3.1.3, Item ‘b’ (7), and language used by roofing industry professionals.

ASHRAE 90.1-2016, Section 5.4.3.1.3, Testing, Acceptable Materials, and Assemblies, reads:
b. Materials that have an air permeance not exceeding 0.004 cfm/ft² under a pressure differential of 0.3 in. of water (1.57 psf) when tested in accordance with ASTM E2178. The following materials meet these requirements:

1. Plywood—minimum 3/8 in.
2. Oriented strand board—minimum 3/8 in.
3. Extruded polystyrene insulation board—minimum 1/2 in.
4. Foil-faced urethane insulation board—minimum 1/2 in.
5. Exterior gypsum sheathing or interior gypsum board—minimum 1/2 in.
6. Cement board—minimum 1/2 in.
7. Built-up roofing membrane
8. Modified bituminous roof membrane
9. Single-ply roof membrane
10. A Portland cement/sand parge, stucco, or gypsum plaster—minimum 1/2 in. thick
11. Cast-in-place and precast concrete
12. Sheet metal
13. Closed-cell 2 lb/ft³ nominal density spray polyurethane foam—minimum 1 in.

NRCA “Guidelines for Air Retarders in roof Assemblies”

**Cost Impact:** The code change proposal will decrease the cost of construction
The number of code-compliant, single-ply roofing material options available will increase; thereby subjecting local, state, regional, and national markets to competitive pricing pressures.
This is a 2 part code change. Part I will be heard by the IECC Commercial Committee. Part II will be heard by the IECC-Residential Committee. See the tentative hearing order for these committees.

2018 International Energy Conservation Code

Revise as follows:

C402.5.3 Rooms containing fuel-burning appliances. Combustion and Solid-Fuel Burning Appliances.
Combustion and solid-fuel burning appliances must be provided with adequate combustion and ventilation air and installed in accordance with manufacturers’ installation instructions; NFPA 54/ANSI Z223.1, National Fuel Gas Code; NFPA 31, Standard for the Installation of Oil-Burning Equipment; or NFPA 211, Standard for Chimneys, Fireplaces, Vents, and Solid-Fuel Burning Appliances, or other equivalent code approved by the code official. In Climate Zones 3 through 8, where combustion air is supplied through openings in an exterior wall to a room or space containing a space-conditioning fuel-burning appliance, one of the following shall apply:

1. The room or space containing the appliance shall be located outside of the building thermal envelope.
2. The room or space containing the appliance shall be enclosed and isolated from conditioned spaces inside the building thermal envelope. Such rooms shall comply with all of the following:
   2.1. The walls, floors and ceilings that separate the enclosed room or space from conditioned spaces shall be insulated to be not less than equivalent to the insulation requirement of below-grade walls as specified in Table C402.1.3 or C402.1.4.
   2.2. The walls, floors and ceilings that separate the enclosed room or space from conditioned spaces shall be sealed in accordance with Section C402.5.1.1.
   2.3. The doors into the enclosed room or space shall be fully gasketed.
   2.4. Water lines and ducts in the enclosed room or space shall be insulated in accordance with Section C402.5.1.1.
   2.5. Where an air duct supplying combustion air to the enclosed room or space passes through conditioned space, the duct shall be insulated to an R-value of not less than R-8.

Exception: Fireplaces and stoves complying with Sections 901 through 905 of the International Mechanical Code, and Section 2111.14 of the International Residential Code.

Add new text as follows:

C402.5.3.1 Testing. Where atmospherically vented combustion appliances or solid-fuel burning appliances are located inside the pressure boundary of the building thermal envelope, the total net exhaust flow of the two largest exhaust fans (not including a summer cooling fan(s) intended to be operated only when windows or other air inlets are open) shall not exceed 15 cfm per 100 ft² (75 L/s per 100 m²) of occupiable space when in operation at full capacity.

Where the designed total net flow exceeds this limit, the net exhaust flow must be reduced by reducing the exhaust flow or providing compensating outdoor air. Gravity or barometric dampers in non-powered exhaust
Add new standard(s) as follows:

**BPI-1200-S-2017: Standard Practice for Basic Analysis of Buildings**

Proposal # 5651

CE103-19 Part I
CE103-19 Part II
IECC: R402.4.4.1 (IRC N1102.4.4.1) (New), BPI Chapter 6

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants LLC, representing Self (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

R402.4.4 (IRC N1102.4.4) Rooms containing fuel-burning appliances. In Climate Zones 3 through 8, where open combustion air ducts provide combustion air to open combustion fuel burning appliances, the appliances and combustion air opening shall be located outside the building thermal envelope or enclosed in a room that is isolated from inside the thermal envelope. Such rooms shall be sealed and insulated in accordance with the envelope requirements of Table R402.1.2, where the walls, floors and ceilings shall meet not less than the basement wall R-value requirement. The door into the room shall be fully gasketed and any water lines and ducts in the room insulated in accordance with Section R403. The combustion air duct shall be insulated where it passes through conditioned space to an Rvalue of not less than R-8.

Exceptions:

1. Direct vent appliances with both intake and exhaust pipes installed continuous to the outside.
2. Fireplaces and stoves complying with Section R402.4.2 and Section R1006 of the International Residential Code.

Add new text as follows:

R402.4.4.1 (IRC N1102.4.4.1) Testing. Where atmospherically vented combustion appliances or solid-fuel burning appliances are located inside the pressure boundary of the building thermal envelope, the total net exhaust flow of the two largest exhaust fans (not including a summer cooling fan(s) intended to be operated only when windows or other air inlets are open) shall not exceed 15 cfm per 100 ft² (75 L/s per 100 m²) of occupiable space when in operation at full capacity.
Where the designed total net flow exceeds this limit, the net exhaust flow must be reduced by reducing the exhaust flow or providing compensating outdoor air. Gravity or barometric dampers in non-powered exhaust makeup air systems shall not be used to provide compensating outdoor air. Atmospherically-vented combustion appliances do not include direct-vent appliances. Combustion appliances that pass safety testing performed in accordance with BPI-1200-S shall be deemed as complying with Section R402.4.4.

Add new standard(s) as follows:

BPI

Building Performance Institute, Inc.
107 Hermes Road, Suite 210
Malta NY 12020
US

Reason: Energy efficiency improvements often have a direct impact on the building pressure boundary affecting the safe operation of combustion equipment. Routinely sealing up buildings without looking at the combustion equipment risk sooner or later will result in harming someone with back-drafted flue gas conditions.

ICC COMMITTEE ACTION HEARINGS ::: April, 2019
The current language requires thermal isolation and enclosure of the mechanical room. A "worst case" depressurization test would, at worst, be equal in estimated first cost.

This proposal is intended to provide clear guidance to builders, code officials and home performance contractors for worst-case testing of atmospheric venting systems where air-sealing techniques and air-leakage performance testing requirements of the 2018 IECC are employed. Worst case testing is used by home performance contractors to identify problems that weaken draft and restrict combustion air. Worst case vent testing uses the home’s exhaust fans, air handling appliances and chimneys to create worst case depressurization in the combustion appliance zone.

Language that is proposed for R403.10 is basically a distilled version of predominant combustion safety test procedures for atmospherically vented appliances found in readily available home performance programs across the country. Specific reference is made to ANSI/BPI-1200, Standard Practice for Basic Analysis of Buildings.

**Cost Impact:** The code change proposal will increase the cost of construction. We suggest that "trading-off" those first costs with the $200 - $300 cost for a "worst case" depressurization test would, at worst, be equal.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ANSI/BPI-1200-S-2017, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
CE104-19

IECC: C402.5.3

Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

Delete without substitution:

C402.5.3 Rooms containing fuel-burning appliances. In Climate Zones 3 through 8, where combustion air is supplied through openings in an exterior wall to a room or space containing a space-conditioning fuel-burning appliance, one of the following shall apply:

1. The room or space containing the appliance shall be located outside of the building thermal envelope.

2. The room or space containing the appliance shall be enclosed and isolated from conditioned spaces inside the building thermal envelope. Such rooms shall comply with all of the following:
   
   2.1. The walls, floors and ceilings that separate the enclosed room or space from conditioned spaces shall be insulated to be not less than equivalent to the insulation requirement of below-grade walls as specified in Table C402.1.3 or C402.1.4.

   2.2. The walls, floors and ceilings that separate the enclosed room or space from conditioned spaces shall be sealed in accordance with Section C402.5.1.1.

   2.3. The doors into the enclosed room or space shall be fully gasketed.

   2.4. Water lines and ducts in the enclosed room or space shall be insulated in accordance with Section C403.

   2.5. Where an air duct supplying combustion air to the enclosed room or space passes through conditioned space, the duct shall be insulated to an R-value of not less than R-8.

Exception: Fireplaces and stoves complying with Sections 901 through 905 of the International Mechanical Code, and Section 2111.14 of the International Building Code.

Reason: The language in the IECC R402.5.3 is deleted in its entirety with no replacement language. Many of the appliances installed today due to Federal Energy Efficiency requirements and customer demands, are direct vent appliances with both intake and exhaust pipes continuous to the outside as listed in exception #1. The concern of this original code change is that the colder air that is installed as combustion air needs to be tempered or conditioned to the temperature of the rest of the building. The thought is that this will save money by not having to warm this colder air once it enters the building. There are advantages to having this open combustion air duct, in the area of the mechanicals in case any of the mechanical combustion appliances need additional air for proper combustion, this opening will supply it. This is a simple safety issue to make combustion air available. Remember, the code is not allowed to create a life safety issue. However the fallacy is in the thought process that this open duct is constantly bringing in cooler or warmer air into the building (depending on the season of the year and your climate zone,). This does not happen. There are some very simple and successful ways to prevent air from entering the building when it’s not needed for combustion. With a 90 degree bend in the duct (the most common way) or placing the end of the duct in a pail or container etc. This can be done without the added costs of building walls around the mechanical room that meet the same requirements of the exterior walls of the home including air leakage, and R-values and U factors of the wall system. The average cost of framing a 10 foot wall is between $150 and $360 for labor and material, depending on location of the country you are building in. Add to that cost an additional $50 to $75 for insulation and another $100 to $150 for
air sealing and the costs add up very fast. These costs don’t even include the average exterior type of door that is required to be gasketed and sealed. Add another $250 to $300 not including Labor. And an additional $50 to $75 for the hardware, frame and door knobs. So where are the savings for meeting this code change? The fact is that the additional costs to do this are between $500.00 on the very low end, and $900 or more, on the higher end. This makes no sense. This code section is trying to solve a problem that does not exist. Especially if the building meets the air tightness requirements of the code already. Also the temperature on both sides of this very expensive wall system is basically the same temperature, why the need for insulation then? Building Physics will dictate that air needs a pressure differential, and a hole, to move air through these walls. Without both a pressure differential and a hole, air will not move. There will not be walls that are separating outside unconditioned air form interior conditioned air, and there will be essentially very little, or no pressure difference from one side of these walls to the other side because there is not going to be a Delta T (Temperature difference). Both sides will be conditioned space. With the cost of housing growing so fast in our country today let’s not keep code changes in the code that cost a lot of money, for no return on the investment (ROI)

Cost Impact: The code change proposal will decrease the cost of construction
The cost factor of doing all this work to isolate theism room if and when a passive combustion air is brought into the space costs so much more than the language of the code will ever save in the first place.

Proposal # 5130
**2018 International Energy Conservation Code**

**C402.5.7 Vestibules.** Building entrances shall be protected with an enclosed vestibule, with all doors opening into and out of the vestibule equipped with self-closing devices. Vestibules shall be designed so that in passing through the vestibule it is not necessary for the interior and exterior doors to open at the same time. The installation of one or more revolving doors in the building entrance shall not eliminate the requirement that a vestibule be provided on any doors adjacent to revolving doors.

**Exceptions:** Vestibules are not required for the following:

1. Buildings in *Climate Zones* 1 and 2.
2. Doors not intended to be used by the public, such as doors to mechanical or electrical equipment rooms, or intended solely for employee use.
3. Doors opening directly from a *sleeping unit* or dwelling unit.
4. Doors opening directly from a space less than 3,000 square feet (298 m²) in area.
5. Revolving doors.
6. Doors used primarily to facilitate vehicular movement or material handling and adjacent personnel doors.
7. Doors that have an air curtain with a velocity of not less than 6.56 feet per second (2 m/s) at the floor that have been tested in accordance with ANSI/AMCA 220 and installed in accordance with the manufacturer’s instructions. Manual or automatic controls shall be provided that will operate the air curtain with the opening and closing of the door. Air curtains and their controls shall comply with Section C408.2.3.

Add new text as follows:

**C402.5.7.1 Vestibules and revolving doors.** Revolving doors shall comply with Section 1010.1.4.1 of the International Building Code. Vestibules shall comply with Section 1010.1.8 of the International Building Code. Where a vestibule serves as part of an accessible route, the vestibule shall also comply Section 404 of ICC A117.1. Automatic doors shall be provided in accordance with Section 1105.1.1 of the International Building Code.

**Reason:** This is a necessary reference for the designer to fully understand the implications for the design of the vestibule given the new automatic door requirements in the IBC and the turning space requirements in the ICC A117.1.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is a pointer to aid the designer.
2018 International Energy Conservation Code

Add new text as follows:

**C402.5.9 Operable openings interlocking. (Mandatory)** Occupancies that utilize an operable opening larger than 40 square feet shall have the openings interlocked with the heating and cooling system to raise the cooling setpoint to 80 degrees or heating to 70 degrees when the operable opening is open in the exterior wall of the building.

**Exceptions:**

1. Food cooking and prep areas that contain equipment that contributes to the mechanical load calculations of a restaurant type occupancy that are zoned separately.
2. Warehouses that utilize overhead doors for the function of the occupancy, where approved by the code official.
3. The first entrance doors where located in the exterior wall and are part of a vestibule system.

**C402.5.9.1 Operable controls (Mandatory)** Controls shall comply with Section C403.13.

**C403.13 Operable opening interlocking controls. (Mandatory)** The heating and cooling systems shall have controls that will interlock these mechanical systems to the set temperatures of 80 degrees for cooling and 70 degrees for heating when the conditions of Section C402.5.9 exist. The controls shall configure to shut off the systems entirely when the outdoor temperatures are below 80 degrees or above 70 degrees.

**Reason:** It has become a frequent practice for large operable windows, roll up doors, and/or sliding or folding doors to be installed and open to take advantage of cross ventilation or wind to assist with cooling and ventilation of a space. The problem has become that the cooling and heating systems for these spaces are still running, which does not assist with the energy efficiency of a building or space. The intent of this proposal is to address this common practice with a practical approach that utilizes similar concepts in other standards and other jurisdictional amendments without “banning” this practice.

The exceptions are needed to address very specific situations this requirement would hinder the function of the space. When preparing food often the equipment utilized is going to increase the need for mechanical cooling, and it is not the intent to cause any discomfort. The exceptions allow for the food prep areas to still utilize the mechanical cooling system. The second exception acknowledges that many warehouses will utilize natural ventilation, and these doors are often opened for this reason. The third exception is to address when the entrance door is opened for people who are coming and going of the space.

The controls for these systems would not need to be on when the outdoor temperatures have reached the set temperatures.

**Cost Impact:** The code change proposal will increase the cost of construction

While this requirement will have an increase of cost on the front end it should decrease the operation cost post construction.

Proposal # 5520
CE107-19
IECC: C403.1.1

Proponent: David Collins, representing SEHPCAC (SEHPCAC@iccsafe.org)

2018 International Energy Conservation Code

Revise as follows:

C403.1.1 Calculation of heating and cooling loads (Mandatory). Design loads associated with heating, ventilating and air conditioning of the building shall be determined in accordance with ANSI/ASHRAE/ACCA Standard 183 or by an approved equivalent computational procedure using the design parameters specified in Chapter 3. Heating and cooling loads shall be adjusted to account for load reductions that are achieved where energy recovery systems are utilized in the HVAC system in accordance with the ASHRAE HVAC Systems and Equipment Handbook by an approved equivalent computational procedure.

Reason:
C403.1.1 is currently called out in C403.3.1, which is labeled mandatory; prior to the reorganization in the 2018 code, it was under charging language 403.2 which was labeled mandatory.

While identified as "Mandatory", if the elimination of the use of the labels "prescriptive “and "mandatory” is approved, we understand this label would not be added and it would instead the provision be added to Table C407.2 to indicate its application to the Total Building Performance compliance option.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Because this is a clarification and reaffirmation of the mandatory nature of this requirement, it should not increase or decrease costs of construction.

Proposal # 4183

CE107-19
Revise as follows:

**COMPUTER ROOM.** A room whose primary function is to house equipment for the processing and storage of electronic data and that which has a design electronic data total ITE equipment power density of less than or equal to 20 watts per square foot (20 watts per 0.092 m$^2$) of conditioned floor area or a connected design electronic data total ITE equipment load of less than or equal to 10 kW.

Add new definition as follows:

**DATA CENTER.** A room, or series of rooms that share data center systems, whose primary function is to house equipment for the processing and storage of electronic data and which has a design total ITE equipment power density exceeding 20 watts per square foot of conditioned area and a total design ITE equipment load greater than 10 kW.

**DATA CENTER SYSTEMS.** HVAC systems and equipment, or portions thereof used to provide cooling or ventilation in a data center.

**INFORMATION TECHNOLOGY EQUIPMENT (ITE)** ITE includes computers, data storage devices, servers, and network/communication equipment.

Revise as follows:

**C403.1 General.** Mechanical systems and equipment serving the building heating, cooling, ventilating or refrigerating needs shall comply with this section.

**Exception:** Data center systems are exempt from the requirements of Sections C403.4 and C403.5.

Add new text as follows:

**C403.1.2 Data Centers** Data center systems shall comply with Sections 6 and 8 of ASHRAE 90.4 with the following changes:

1. Replace design MLC values in the ASHRAE 90.4 specified in Table 6.2.1.1 with the values in Table C403.1.2(1) as applicable in each climate zone.
2. Replace annualized MLC values in the ASHREA 90.4 specified in Table 6.2.1.2 with the values in Table C403.1.2(2) as applicable in each climate zone.

**C403.1.2(1)**

For SI: 1 British thermal unit per hour = 0.2931 W.

a. Net sensible cooling capacity: the total gross cooling capacity less the latent cooling less the energy to the air movement system. (Total Gross – latent – Fan Power).

b. Sensible coefficient of performance (SCOP-127): a ratio calculated by dividing the net sensible cooling capacity in watts by the total power input in watts (excluding reheaters and humidifiers).
at conditions defined in ASHRAE Standard 127. The net sensible cooling capacity is the gross sensible capacity minus the energy dissipated into the cooled space by the fan system.

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption. Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2. Transformers, uninterruptable power supplies, motors and electrical power processing equipment in data center systems shall comply with Section 8 of ASHRAE 90.4 in addition to this code.

a. In cases where both a common space type and a building area specific space type are listed, the building area specific space type shall apply.
b. A ‘Facility for the Visually Impaired’ is a facility that is licensed or will be licensed by local or state authorities for senior long-term care, adult daycare, senior support or people with special visual needs.
c. Where sleeping units are excluded from lighting power calculations by application of Section R405.1, neither the area of the sleeping units nor the wattage of lighting in the sleeping units is counted.
d. Where dwelling units are excluded from lighting power calculations by application of Section R405.1, neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.
e. Class I facilities consist of professional facilities; and semiprofessional, collegiate, or club facilities with seating for 5,000 or more spectators.
f. Class II facilities consist of collegiate and semiprofessional facilities with seating for fewer than 5,000 spectators; club facilities with seating for between 2,000 and 5,000 spectators; and amateur league and high-school facilities with seating for more than 2,000 spectators.
g. Class III facilities consist of club, amateur league and high-school facilities with seating for 2,000 or fewer spectators.
h. Class IV facilities consist of elementary school and recreational facilities; and amateur league and high-school facilities without provision for spectators.

Add new standard(s) as follows:

**ASHRAE**

**90.4-2016: Energy Standard for Data Centers**

**Reason:** Data centers have long had difficulty meeting all prescriptive code requirements and are additionally discouraged from pursuing more efficient alternatives with useful waste heat. Instead of current prescriptive...
code language (emphasizing component performance ratings and cooler-weather economization) this proposal seeks to require large sophisticated data center projects to meet a performance-based ASHRAE Standard allowing attractive system-wide tradeoffs for efficiency and explicit credit for useful heat recovery. While data centers pursuing this path may experience energy savings, this proposal seeks to instill a performance-based approach to encourage more efficient design overall using a methodology that better suits this unique building type.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. We do not anticipate any significant financial impacts to be incurred due to this change.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ASHRAE 90.4-2016, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

**Analysis:** A review of the standard proposed for inclusion in the code, ASHRAE 90.4-2016, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 4949

CE108-19
CE109-19
IECC: C403.2.2.1 (New)

Proponent: Joel Williams, TEXENERGY SOLUTIONS, representing TexEnergy Solutions

2018 International Energy Conservation Code
Add new text as follows:

C403.2.2.1 Multifamily ventilation addition. For unitary systems less than 65,000 KBTU/Yr serving a multifamily dwelling unit with a individual ventilation system having a fan either partially or completely dedicated to ventilation shall have a fan size no larger than ¼ horsepower.

Reason: We work mostly in multifamily commercial construction. The intent of this change is to move away from the primary strategy for ventilation (CZ1-3) being a duct with a damper attached to the return plenum. This brings in additional moisture due to the lack of control and design of the system.

Bibliography: Performance path energy models (REMRate/Ekotrope) for low-rise apartments do a good job of showing this impact. They take the fan power for the apartments and compare them against a baseline of 2.2 CFM/Watt (0.46 W/CFM) for the ventilation of the building and rate it on how many hours a day that it will run. It disincentivizes the air handler strategy in the performance code path and helps promote a more effective ventilation system.

Cost Impact: The code change proposal will increase the cost of construction
Since this is multifamily construction, most of the units are between 1.5T and 3.0T in sizing. Most projects use the air handler fan and put a duct with a damper to bring in the fresh air for their apartments. This would force a decision to buy more efficient equipment and not upsize the air handler to get a higher equipment efficiency at the detriment of the additional power used by the ventilation fan strategy.

Proposal # 5137
Add new definition as follows:

**FAULT DETECTION AND DIAGNOSTICS (FDD) SYSTEM.** A software platform that utilizes building analytic algorithms to convert data provided by sensors and devices to automatically identify faults in building systems and provide a prioritized list of actionable resolutions to those faults based on cost or energy avoidance, comfort and maintenance impact.

Revise as follows:

**C403.2 System design (Mandatory).** Mechanical systems shall be designed to comply with Sections C403.2.1 and C403.2.2. Where elements of a building’s mechanical systems are addressed in Sections C403.3 through C403.12, such elements shall comply with the applicable provisions of those sections.

Add new text as follows:

**C403.2.3 Fault Detection and Diagnostics (Mandatory).** Buildings having 100,000 square feet (9,290 square meters) or more of conditioned floor area shall include a fault detection and diagnostics (FDD) system to monitor the building's HVAC system's performance and automatically identify faults. The FDD system shall:

1. Utilize permanently installed sensors and devices to monitor the HVAC system's central plant equipment, zone terminal equipment and associated mechanical components including but not limited to motors, actuators, valves and dampers;
2. Sample the permanently installed sensors and devices at least once per 15 minutes;
3. Automatically identify HVAC system faults using algorithmic-based analysis that performs rule-based or model-based diagnostics separately from the monitoring and alarming functionality of a building management system (BMS) or building automation system (BAS);
4. Automatically provide authorized personnel with prioritized recommendations for fault repair of identified faults based on estimated excess energy consumption or cost of non-repair; and
5. Be capable of transmitting the prioritized fault repair recommendations to remotely located authorized personnel.

**Reason:** The purpose of this code change proposal is to add a requirement for Fault Detection and Diagnostics (FDD) for HVAC systems in large commercial buildings. Energy efficiency of a new building’s HVAC system will degrade over time if equipment is poorly maintained, failing, or improperly controlled. The proposed FDD requirement will reduce that degradation by detecting HVAC system faults and notifying building operators so that corrective actions may be taken to repair the faults and reduce the energy consumption of the building. In addition, FDD systems are commonly utilized to drive operational efficiency, make better use of maintenance personnel, and resolve comfort issues.
Cost Impact: The code change proposal will increase the cost of construction because it will require additional hardware, software and/or labor during installation of the mechanical system. However, based on field experience with FDD systems, we believe that these systems will rapidly pay for themselves. A recent study of a FDD system installed in a research lab in Massachusetts showed that the equipment would produce a return on investment of less than one year. See “Realizing ongoing energy and cost savings,” available at https://ecobuilding.schneider-electric.com/documents/10807/217223/Lab+Project+Building+Analytics+Case+Study/a6d8b9b6-7fdd-4e87-a90b-c98ece595a25:

- Setup cost: $23,190
- Annual maintenance cost: $35,407
- Projected annual savings: $286,000

Proposal # 4206
2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new text as follows:

FAULT DETECTION AND DIAGNOSTICS (FDD) SYSTEM A software platform that utilizes building analytic algorithms to convert data provided by sensors and devices to automatically identify faults in building systems and provide a prioritized list of actionable resolutions to those faults based on cost or energy avoidance, comfort and maintenance impact.

Revise as follows:

C403.2 System design (Mandatory). Mechanical systems shall be designed to comply with Sections C403.2.1 and C403.2.2. through C403.2.3. Where elements of a building’s mechanical systems are addressed in Sections C403.3 through C403.12, such elements shall comply with the applicable provisions of those sections.

Add new text as follows:

C403.2.3 Fault Detection and Diagnostics (Mandatory) New buildings with a gross conditioned floor area of 100,000 square feet (9290 square meters) or larger shall include a fault detection and diagnostics (FDD) system to monitor the HVAC system's performance and automatically identify faults. The FDD system shall:
1. Include permanently installed sensors and devices to monitor the HVAC system's performance;
2. Sample the HVAC system's performance at least once per 15 minutes;
3. Automatically identify and report HVAC system faults;
4. Automatically notify authorized personnel of identified HVAC system faults;
5. Automatically provide prioritized recommendations for repair of identified faults based on analysis of data collected from the sampling of HVAC system performance; and
6. Be capable of transmitting the prioritized fault repair recommendations to remotely located authorized personnel.

Reason: Energy efficiency of a new building’s HVAC system will degrade over time caused by poorly maintained, failing and improperly controlled equipment. The proposed FDD requirement will reduce that degradation by detecting HVAC system faults and notifying building operators so that actions may be taken to reduce energy consumption of the building. Additionally, FDD systems are being utilized to drive operational efficiency, make better use of maintenance personnel, and resolve comfort issues.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal “will” increase the cost of construction because it will require additional hardware, software and labor during installation. Providing specific cost would violate antitrust laws, however a published example of cost and savings is provided from the following link https://ecobuild.schneider-electric.com/documents/10807/217223/Lab+Project+Building+Analytics+Case+Study/a6d8b9b6-7fdd-4e87-a90b-c98ece595a25: Setup/install cost - $23,190, Annual maintenance cost - $35,407, and Annual savings - $286,000.

</tbody>
</table>

For SI: 1 British thermal unit per hour = 0.2931 W.

a. These requirements apply to boilers with rated input of 8,000,000 Btu/h or less that are not packaged boilers and to all packaged boilers. Minimum efficiency requirements for boilers cover all capacities of packaged boilers.

b. Maximum capacity – minimum and maximum ratings as provided for and allowed by the unit’s controls.

c. Includes oil-fired (residual).

d. \( E_c \) = Combustion efficiency (100 percent less flue losses).

e. \( E_i \) = Thermal efficiency. See referenced standard for detailed information.

f. Boilers shall not be equipped with a constant-burning ignition pilot.

g. A boiler not equipped with a tankless domestic water heating coil shall be equipped with an
automatic means for adjusting the temperature of the water such that an incremental change in inferred heat load produces a corresponding incremental change in the temperature of the water supplied.

**Reason:** This will align the IECC with the required minimum efficiency values shown in ASHRAE 90.1-2016 (and 2013, 2010, and 2007) Table 6.8.1-6, "Gas and Oil Fired Boilers - Minimum Efficiency Requirements". These values were agreed to on a consensus basis by the ASHRAE Mechanical SubCommittee, the ASHRAE 90.1 Full Committee, and then went out for public review before being published.

**Cost Impact:** The code change proposal will increase the cost of construction. There will be an increase in cost to install higher efficiency equipment.

Proposal # 4726

CE112-19
2018 International Energy Conservation Code

Revise as follows:

C403.3.2 HVAC equipment performance requirements (Mandatory). Equipment shall meet the minimum efficiency requirements of Tables C403.3.2(1) through C403.3.2(9) 6.8.1-1 through 6.8.1-19 of ASHRAE Standard 90.1 when tested and rated in accordance with the applicable test procedure. Plate-type liquid-to-liquid heat exchangers shall meet the minimum requirements of Table C403.3.2(10). 6.8.1-8 of ASHRAE Standard 90.1. The efficiency shall be verified through certification under an approved certification program or, where a certification program does not exist, the equipment efficiency ratings shall be supported by data furnished by the manufacturer. Where multiple rating conditions or performance requirements are provided, the equipment shall satisfy all stated requirements. Where components, such as indoor or outdoor coils, from different manufacturers are used, calculations and supporting data shall be furnished by the designer that demonstrates that the combined efficiency of the specified components meets the requirements herein.

For SI: 1 British thermal unit per hour = 0.2931 W.

- Chapter 6 contains a complete specification of the referenced test procedure, including the referenced year version of the test procedure.
- Minimum and maximum ratings as provided for and allowed by the unit’s controls.
- Combination units not covered by the National Appliance Energy Conservation Act of 1987 (NAECA) (3-phase power or cooling capacity greater than or equal to 65,000 Btu/h [19 kW]) shall comply with either rating.
- \(E_o\) = Thermal efficiency. See test procedure for detailed discussion.
- \(E_o\) = Combustion efficiency (100% less flue losses). See test procedure for detailed discussion.
- \(E_o\) = Combustion efficiency. Units shall also include an IID, have jackets not exceeding 0.75 percent of the input rating, and have either power venting or a flue damper. A vent damper is an acceptable alternative to a flue damper for those furnaces where combustion air is drawn from the conditioned space.
- \(E_o\) = Thermal efficiency. Units shall also include an IID, have jacket losses not exceeding 0.75 percent of the input rating, and have either power venting or a flue damper. A vent damper is an acceptable alternative to a flue damper for those furnaces where combustion air is drawn from the conditioned space.

</tbody>
</table>

For SI: 1 British thermal unit per hour = 0.2931 W.

- **a.** These requirements apply to boilers with rated input of 8,000,000 Btu/h or less that are not packaged boilers and to all packaged boilers. Minimum efficiency requirements for boilers cover all capacities of packaged boilers.
- **b.** Maximum capacity—minimum and maximum ratings as provided for and allowed by the unit’s controls.
- **c.** Includes oil-fired (residual).
- **d.** <i>E<sub>t</sub></i> = Combustion efficiency (100 percent less flue losses).
- **e.** <i>E<sub>t</sub></i> = Thermal efficiency. See referenced standard for detailed information.
- **f.** Boilers shall not be equipped with a constant burning ignition pilot.
- **g.** A boiler not equipped with a tankless domestic water heating coil shall be equipped with an automatic means for adjusting the temperature of the water such that an incremental change in inferred heat load produces a corresponding incremental change in the temperature of the water supplied.

---

**a.** The requirements for centrifugal chiller shall be adjusted for nonstandard rating conditions in accordance with Section C403.3.2.1 and are only applicable for the range of conditions listed in Section C403.3.2.1. The requirements for air-cooled, water-cooled positive displacement and absorption chillers are at standard rating conditions defined in the reference test procedure.

**b.** Both the full-load and IPLV requirements shall be met or exceeded to comply with this standard. Where there is a Path B, compliance can be with either Path A or Path B for any application.

**c.** NA means the requirements are not applicable for Path B and only Path A can be used for compliance.

**d.** FL represents the full-load performance requirements and IPLV the part-load performance requirements.

</tbody>
</table>

For SI: °C = [(°F) -32] / 1.8, L/s \( \times \) kW = (gpm/ hp)/(11.83), COP = (Btu/h \( \times \) hp)/(2550.7);

db = dry-bulb temperature, °F, wb = wet-bulb temperature, °F.

<sup>a</sup> The efficiencies and test procedures for both open- and closed-circuit cooling towers are not applicable to hybrid cooling towers that contain a combination of wet and dry heat exchange...
For purposes of this table, open circuit cooling tower performance is defined as the water flow rating of the tower at the thermal rating condition, divided by the fan nameplate-rated motor power.

For purposes of this table, closed-circuit cooling tower performance is defined as the water flow rating of the tower at the thermal rating condition, divided by the sum of the fan nameplate-rated motor power and the spray pump nameplate-rated motor power.

For purposes of this table, air-cooled condenser performance is defined as the heat rejected from the refrigerant divided by the fan nameplate-rated motor power.

Chapter 6 contains a complete specification of the referenced test procedure, including the referenced year version of the test procedure. The certification requirements do not apply to field-erected cooling towers.

Where a certification program exists for a covered product and it includes provisions for verification and challenge of equipment efficiency ratings, then the product shall be listed in the certification program; or, where a certification program exists for a covered product, and it includes provisions for verification and challenge of equipment efficiency ratings, but the product is not listed in the existing certification program, the ratings shall be verified by an independent laboratory test report.

Cooling towers shall comply with the minimum efficiency listed in the table for that specific type of tower with the capacity effect of any project-specific accessories or options included in the capacity of the cooling tower.

For purposes of this table, evaporative condenser performance is defined as the heat rejected at the specified rating condition in the table divided by the sum of the fan motor nameplate power and the integral spray pump nameplate power.

Requirements for evaporative condensers are listed with ammonia (R-717) and R-507A as test fluids in the table. Evaporative condensers intended for use with halocarbon refrigerants other than R-507A shall meet the minimum efficiency requirements listed in this table with R-507A as the test fluid.

<sup>a</sup> The capacity of any project-specific accessories or options included in the capacity of the cooling tower.

<sup>b</sup> SCOP-127 efficiency is calculated as the ratio of the heat rejected from the refrigerant to the sum of the fan motor nameplate power and the integral spray pump nameplate power.
For SI: 1 British thermal unit per hour = 0.2931 W.

a. Net sensible cooling capacity: the total gross cooling capacity less the latent cooling less the energy to the air movement system. (Total Gross — latent — Fan Power).

b. Sensible-coefficient of performance (SCOP-127): a ratio calculated by dividing the net sensible cooling capacity in watts by the total power input in watts (excluding reheaters and humidifiers) at conditions defined in ASHRAE Standard 127. The net sensible cooling capacity is the gross sensible capacity minus the energy dissipated into the cooled space by the fan system.

NR = No Requirement.

a. Chapter 6 contains a complete specification of the referenced test procedure, including the referenced year version of the test procedure.

#### C403.3.2.1 Water-cooled centrifugal chilling packages (Mandatory).

Equipment not designed for operation at AHRI Standard 550/590 test conditions of 44°F (7°C) leaving chilled-water temperature and 2.4 gpm/ton evaporator fluid flow and 85°F (29°C) entering condenser water temperature with 3 gpm/ton (0.054 l/s • kW) condenser water flow shall have maximum full-load kW/ton (FL) and part-load ratings requirements adjusted using Equations 4-6 and 4-7.

\[
F_{L_{adj}} = FL / K_{adj}
\]
(Equation 4-6)

\[
PLV_{adj} = |PLV/K_{adj}|
\]
(Equation 4-7)

where:

\[
K_{adj} = A \times B
\]
\[ FL = \text{Full-load kW/ton value as specified in Table C403.3.2(7) the tables in Section C403.3.2.} \]

\[ FL_{\text{adj}} = \text{Maximum full-load kW/ton rating, adjusted for nonstandard conditions.} \]

\[ IPLV = \text{Value as specified in Table C403.3.2(7) the tables in Section C403.3.2.} \]

\[ PLV_{\text{adj}} = \text{Maximum } NPLV \text{ rating, adjusted for nonstandard conditions.} \]

\[ A = 0.00000014592 \times (LIFT)^4 - 0.0000346496 \times (LIFT)^3 + 0.00314196 \times (LIFT)^2 - 0.147199 \times (LIFT) + 3.9302 \]

\[ B = 0.0015 \times L_{vgE_{\text{evap}}} + 0.934 \]

\[ LIFT = L_{vgC_{\text{ond}}} - L_{vgE_{\text{evap}}} \]

\[ L_{vgC_{\text{ond}}} = \text{Full-load condenser leaving fluid temperature (°F).} \]

\[ L_{vgE_{\text{evap}}} = \text{Full-load evaporator leaving temperature (°F).} \]

The \( FL_{\text{adj}} \) and \( PLV_{\text{adj}} \) values are only applicable for centrifugal chillers meeting all of the following full-load design ranges:

1. Minimum evaporator leaving temperature: 36°F.
2. Maximum condenser leaving temperature: 115°F.
3. 20°F ≤ LIFT ≤ 80°F.

**C403.3.2.2 Positive displacement (air- and water-cooled) chilling packages.** Equipment with a leaving fluid temperature higher than 32°F (0°C) and water-cooled positive displacement chilling packages with a condenser leaving fluid temperature below 115°F (46°C) shall meet the requirements of Table C403.3.2(7) the tables in Section C403.3.2. when tested or certified with water at standard rating conditions, in accordance with the referenced test procedure.

**C403.5.5 Economizer fault detection and diagnostics (Mandatory).** Air-cooled unitary direct-expansion units listed in Tables C403.3.2(1) through C403.3.2(3) the tables in Section C403.3.2. and variable refrigerant flow (VRF) units that are equipped with an economizer in accordance with Sections C403.5 through C403.5.4 shall include a fault detection and diagnostics system complying with the following:

1. The following temperature sensors shall be permanently installed to monitor system operation:
   1.1. Outside air.
   1.2. Supply air.
   1.3. Return air.
2. Temperature sensors shall have an accuracy of ±2°F (1.1°C) over the range of 40°F to 80°F (4°C to 26.7°C).
3. Refrigerant pressure sensors, where used, shall have an accuracy of ±3 percent of full scale.
4. The unit controller shall be configured to provide system status by indicating the following:
   4.1. Free cooling available.
   4.2. Economizer enabled.
   4.3. Compressor enabled.
   4.4. Heating enabled.
   4.5. Mixed air low limit cycle active.
   4.6. The current value of each sensor.
5. The unit controller shall be capable of manually initiating each operating mode so that the operation of compressors, economizers, fans and the heating system can be independently
6. The unit shall be configured to report faults to a fault management application available for access by day-to-day operating or service personnel, or annunciated locally on zone thermostats.

7. The fault detection and diagnostics system shall be configured to detect the following faults:
   7.1. Air temperature sensor failure/fault.
   7.2. Not economizing when the unit should be economizing.
   7.3. Economizing when the unit should not be economizing.
   7.4. Damper not modulating.
   7.5. Excess outdoor air.

C403.9 Heat rejection equipment. Heat rejection equipment, including air-cooled condensers, dry coolers, open-circuit cooling towers, closed-circuit cooling towers and evaporative condensers, shall comply with this section.

Exception: Heat rejection devices where energy usage is included in the equipment efficiency ratings listed in Tables C403.3.2(6) and C403.3.2(7) the tables in Section C403.3.2.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) the tables in Section C403.3.2 by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity.

<p>| TABLE C407.5.1(1) SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS |
|-----------------------------------|-----------------------------------|-----------------------------------|
| <strong>BUILDING COMPONENT CHARACTERISTICS</strong> | <strong>STANDARD REFERENCE DESIGN</strong> | <strong>PROPOSED DESIGN</strong> |
| Space use classification | Same as proposed | The space use classification shall be chosen in accordance with Table C405.5.2 for all areas of the building covered by this permit. Where the space use classification for a building is not known, the building shall be categorized as an office building. |
| Roofs | Type: Insulation entirely above deck | As proposed |
| | Gross area: same as proposed | As proposed |
| | U-factor: as specified in Table C402.1.4 | As proposed |
| | Solar absorptance: 0.75 | As proposed |
| | Emittance: 0.90 | As proposed |
| Walls, above-grade | Type: Mass wall where proposed wall is mass; otherwise steel-framed wall | As proposed |
| | Gross area: same as proposed | As proposed |
| | U-factor: as specified in Table C402.1.4 | As proposed |
| Walls, below-grade | Solar absorptance: 0.75 | As proposed |
| | Emittance: 0.90 | As proposed |
| | Type: Mass wall | As proposed |
| | Gross area: same as proposed | As proposed |
| | $U$-Factor: as specified in Table C402.1.4 with insulation layer on interiorside of walls | As proposed |
| Floors, above-grade | Type: joist/framed floor | As proposed |
| | Gross area: same as proposed | As proposed |
| | $U$-Factor: as specified in Table C402.1.4 | As proposed |
| Floors, slab-on-grade | Type: Unheated | As proposed |
| | $F$-factor: as specified in Table C402.1.4 | As proposed |
| Opaque doors | Type: Swinging | As proposed |
| | Area: Same as proposed | As proposed |
| | $U$-Factor: as specified in Table C402.1.4 | As proposed |
| Vertical fenestration other than opaque doors | Area 1. The proposed vertical fenestration area; where the proposed vertical fenestration area is less than 40 percent of above-grade wall area. | As proposed |
| | 2. 40 percent of above-grade wall area; where the proposed vertical fenestration area is 40 percent or more of the above-grade wall area. | |
| | $U$-Factor: as specified in Table C402.4 | As proposed |
| | SHGC: as specified in Table C402.4 except that for climates with no requirement (NR) SHGC = 0.40 shall be used | As proposed |
| | External shading and PF: None | As proposed |</p>
<table>

</table>

| Lighting, interior | The interior lighting power shall be determined in accordance with Section C405.3.2. Where the occupancy of the building is not known, the lighting power density shall be 1.0 Watt per square foot (10.7 W/m\(^2\)) based on the categorization of buildings with unknown space classification as offices. | As proposed |

| Lighting, exterior | The lighting power shall be determined in accordance with Table C405.4.2(2) and C405.4.2(3). Areas and dimensions of surfaces shall be the same as proposed. | As proposed |

| Internal gains | Same as proposed | Receptacle, motor and process loads shall be modeled and estimated based on the space use classification. End-use load components within and associated with the building shall be modeled to include, but not be limited to, the following: exhaust fans, parking garage ventilation fans, exterior building lighting, swimming pool heaters and pumps, elevators, escalators, refrigeration equipment and cooking equipment. |
### Schedules

**Exception:** Thermostat settings and schedules for HVAC systems that utilize radiant heating, radiant cooling and elevated air speed, provided that equivalent levels of occupant thermal comfort are demonstrated by means of equal Standard Effective Temperature as calculated in Normative Appendix B of ASHRAE Standard 55.

Operating schedules shall include hourly profiles for daily operation and shall account for variations between weekdays, weekends, holidays and any seasonal operation. Schedules shall model the time-dependent variations in occupancy, illumination, receptacle loads, thermostat settings, mechanical ventilation, HVAC equipment availability, service hot water usage and any process loads. The schedules shall be typical of the proposed building type as determined by the designer and approved by the jurisdiction.

</tbody>
</table>

SWHF = Service water heat recovery factor, DWHR = Drain water heat recovery.

- **a.** Where no heating system exists or has been specified, the heating system shall be modeled as fossil fuel. The system characteristics shall be identical in both the standard reference design and proposed design.
- **b.** The ratio between the capacities used in the annual simulations and the capacities determined by sizing runs shall be the same for both the standard reference design and proposed design.
- **c.** Where no cooling system exists or no cooling system has been specified, the cooling system shall be modeled as an air-cooled single-zone system, one unit per thermal zone. The system characteristics shall be identical in both the standard reference design and proposed design.
- **d.** If an economizer is required in accordance with Table C403.5(1) and where no economizer exists or is specified in the proposed design, then a supply-air economizer shall be provided in the standard reference design in accordance with Section C403.5.
- **e.** The SWHF shall be applied as follows:
  1. Where potable water from the DWHR unit supplies not less than one shower and not greater than two showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = \([1 - \text{DWHR unit efficiency} \times 0.36]\).
  2. Where potable water from the DWHR unit supplies not less than three showers and not greater than four showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = \([1 - \text{DWHR unit efficiency} \times 0.33]\).
  3. Where potable water from the DWHR unit supplies not less than five showers and not greater than six showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = \([1 - \text{DWHR unit efficiency} \times 0.26]\).
  4. Where Items 1 through 3 are not met, SWHF = 1.0.

**C408.2.3.1 Equipment.** Equipment functional performance testing shall demonstrate the installation and
operation of components, systems, and system-to-system interfacing relationships in accordance with approved plans and specifications such that operation, function, and maintenance serviceability for each of the commissioned systems is confirmed. Testing shall include all modes and sequence of operation, including under full-load, part-load and the following emergency conditions:

1. All modes as described in the sequence of operation.
2. Redundant or automatic back-up mode.
4. Mode of operation upon a loss of power and restoration of power.

**Exception:** Unitary or packaged HVAC equipment listed in Tables C403.3.2(1) through C403.3.2(3) the tables in Section C403.3.2 that do not require supply air economizers.

**Reason:** These tables have historically come from ASHRAE Standard 90.1. They all represent industry consensus, and are rarely, if ever, intended to be different than 90.1. During the last few code cycles, we have noticed that due to the processes, the tables tend to diverge. The reason for this is that public comments to the IECC are due before the final tables are developed and generated for 90.1. Typically, we find errata in the 90.1 tables when we are developing the print version of the standard. Due to timing, those corrections in 90.1 never make it into the IECC. By referencing these tables in 90.1, we ensure that the requirements are aligned. ASHRAE also recognizes that code officials want to have the tables in the book. If this proposal is accepted, ASHRAE has contacted ICC staff about the possibility of reprinting the necessary tables in the IECC as printed in 90.1.

This proposal intends to modify the code by extracting and reprinting the following Tables from ASHRAE Standard 90.1-2019:

**Table 6.8.1-1 Electrically Operated Unitary Air Conditioners and Condensing Units—Minimum Efficiency Requirements**

**Table 6.8.1-2 Electrically Operated Air Cooled Unitary and Heat Pumps—Minimum Efficiency Requirements**

**Table 6.8.1-3 Water-Chilling Packages—Minimum Efficiency Requirements**

**Table 6.8.1-4 Electrically Operated Packaged Terminal Air Conditioners, Packaged Terminal Heat Pumps, Single-Package Vertical Air Conditioners, Single-Package Vertical Heat Pumps, Room Air Conditioners, and Room Air Conditioner Heat Pumps—Minimum Efficiency Requirements**

**Table 6.8.1-5 Warm-Air Furnaces and Combination Warm-
Air Furnaces/Air-Conditioning Units, Warm-Air Duct Furnaces, and Unit Heaters—Minimum Efficiency Requirements

Table 6.8.1-6 Gas- and Oil-Fired Boilers—Minimum Efficiency Requirements

Table 6.8.1-7 Performance Requirements for Heat Rejection Equipment—Minimum Efficiency Requirements

Table 6.8.1-8 Heat Transfer Equipment—Minimum Efficiency Requirements

Table 6.8.1-9 Electrically Operated Variable-Refrigerant-Flow Air Conditioners—Minimum Efficiency Requirements

Table 6.8.1-10 Electrically Operated Variable-Refrigerant-Flow and Applied Heat Pumps—Minimum Efficiency Requirements

Table 6.8.1-11 Floor Mounted Air Conditioners and Condensing Units Serving Computer Rooms—Minimum Efficiency Requirements

Table 6.8.1-13 Commercial Refrigerators, Freezers and Refrigeration—Minimum Efficiency Requirements

Table 6.8.1-14 Vapor Compression Based Indoor Pool Dehumidifiers—Minimum Efficiency Requirements

Table 6.8.1-15 Electrically Operated DX-DOAS Units, Single-Package and Remote Condenser, without Energy Recovery—Minimum Efficiency Requirements

Table 6.8.1-16 Electrically Operated DX-DOAS Units, Single-Package and Remote Condenser, with Energy Recovery—Minimum Efficiency Requirements

Table 6.8.1-17 Electrically Operated Water Source Heat
Pumps—Minimum Efficiency Requirements

Table 6.8.1-18 Heat Pump and Heat Reclaim Chiller Packages – Minimum Efficiency Requirements

Table 6.8.1-19 Ceiling Mounted Computer Room Air Conditioners—Minimum Efficiency Requirements

This proposal does add new tables for DOAS units, electrically operated water source heat pumps, heat pump and heat reclaim chiller packages, ceiling mounted computer room air conditioners, and commercial refrigerators and freezers that were previously not covered in the IECC.

The proposal includes six sections and a table which contain specific references to one or more individual tables in Section C403.3.2. In each of these the specific references are replaced by a generic reference to the tables in Section C403.3.2. It is our intent that any other sections which have a specific reference, that it will also be replaced by the generic reference.

Please note that replacement of the IECC tables will result in the following standards no longer being directly referenced in the IECC: AHRI 210/240, AHRI 340/360, AHRI 365, AHRI 390, AHRI 400, AHRI 460, AHRI 560, ANSI/AHAM RAC-1, ANSI Z21.47, ANSI Z83.8, ASHRAE 127, CTI ATC-105, CTI ATC 105S, CTI STD-201 RS, CTI ATC-106, CTI STD 201, ISO 13256-1, ISO 13256-2, UL727, UL731 and NAECA.

Bibliography: ANSI/ASHRAE/IES Standard 90.1

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Some efficiencies in 90.1 for various types of equipment have been changed, and there are some new efficiencies for products that were previously uncovered. In some of those instances, the cost of construction may increase.
CE114-19

IECC: C403.3.3, C403.3.4

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

**C403.3.3 Hot gas bypass limitation (Mandatory).** Cooling systems shall not use hot gas bypass or other evaporator pressure control systems unless the system is designed with multiple steps of unloading or continuous capacity modulation. The capacity of the hot gas bypass shall be limited as indicated in Table C403.3.3, as limited by Section C403.5.1.

**C403.3.4 Boiler turndown (Mandatory).** Boiler systems with design input of greater than 1,000,000 Btu/h (293 kW) shall comply with the turndown ratio specified in Table C403.3.4. The system turndown requirement shall be met through the use of multiple single-input boilers, one or more modulating boilers or a combination of single-input and modulating boilers.

Reason:
While hot gas bypass limitations and boiler turn down are not technically impossible to model, it is generally considered infeasible to do so. Even if it were to be modeled verifying the assumptions used for the model would be virtually impossible. It is only theoretically tradable, and is not typically – if ever - traded by users of the performance path.

As essentially non-tradeable, C403.3.3 and C403.3.4 should be labeled as mandatory.

Note that SEHPCAC has a proposal to eliminate the use of the labels "prescriptive “and "mandatory" in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as 'mandatory' will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at:
http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx
(http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx)

Cost Impact: The code change proposal will increase the cost of construction
As commonly interpreted, these items are already considered mandatory and would have no impact on cost. However, it may increase the cost of construction for a subset of buildings designed to comply with Section C407 that do not include the specified hot gas bypass limitations or boiler turndown provisions included in Section C403.3.3 and C403.3.4.

Proposal # 4185
CE115-19 Part I

PART I — IECC: Part I: C403.4.1.1 (New)
IECC: Part II: R403.1.2(N1103.1.2) (New)

PART II — IECC: R403.1.2 (IRC N1103.1.2)

Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC-COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Add new text as follows:

C403.4.1.1 Heat pump supplemental heat (Mandatory). Heat pumps having supplemental electric resistance heat shall have controls that prevent supplemental heat operation where the heat pump vapor compression cycle can provide the necessary heating to satisfy the thermostat control.

Exceptions:

1. Defrost operation.
2. Vapor compression cycle malfunction.
3. Thermostat malfunction.

Proposal # 4115
CE115-19 Part II

IECC: R403.1.2 (IRC N1103.1.2)

**Proponent:** Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

R403.1.2 (IRC N1103.1.2) *Heat pump supplementary supplemental heat (Mandatory).* Heat pumps having supplementary supplemental electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation when the heat pump compressor can meet the heating load. **Vapor compression cycle** can provide the necessary heating to satisfy the thermostat control.

**Exceptions:**

1. **Defrost operation.**
2. **Vapor compression cycle heating malfunction.**
3. **Thermostat malfunction.**

**Reason:** This proposal updates this requirement to account for real world operation of heat pumps. There are times when supplemental heat will be needed to be used apart from defrost operation. The reasons for the additional exceptions are as follows: **Vapor compression cycle heating malfunction.** If the compressor or reversing valve or metering device (such as a capillary tube or thermal expansion valve) is not working properly, the current requirements do not allow supplemental heat to be used. As a result, the space will not be conditioned, and in extreme cases where the compressor is not fixed, the temperatures could fall to levels where unsafe situations (such as pipes freezing) could develop.

**Thermostat malfunction.** If the thermostat is not working properly, the current requirements do not allow supplemental heat to be used. As a result, the space may not be conditioned, and when the thermostat is repaired, supplemental heat may be needed in conjunction with the compressor and fan motor to get the space back to its programmed temperature in a short period of time.

It should also be noted that the national energy efficiency standards for residential heat pumps have increased significantly over the past 25 years, and will increase again in January, 2023. Also, with more heat pumps having "smart" technology, the system owner can be notified immediately on a smart phone or computer if such a malfunction is occurring, which will limit such operation.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This will not increase (or decrease) the cost of construction, as the exceptions shown are already aspects of current heat pump control strategies and will not increase the cost to purchase, install, or operate a heat pump.

Proposal # 4104
CE116-19 Part I

PART I — IECC: C403.4.1.1
PART II — IECC: R403.1.2 (IRC N1103.1.2)

Proponent: Charles Foster, representing self (cfoster20187@yahoo.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C403.4.1.1 Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric resistance heat shall have controls that — except during defrost, prevent supplementary heat operation where the heat pump can provide the heating load. limit supplemental heat operation to only those times when:

1. The vapor compression cycle cannot provide the necessary heating energy to satisfy the thermostat setting.
2. The heat pump is operating in defrost mode.
3. The vapor compression cycle malfunctions, or
4. The thermostat malfunctions.

Proposal # 4971
CE116-19 Part II

IECC: R403.1.2 (IRC N1103.1.2)

Proponent: Charles Foster, representing self (cfoster20187@yahoo.com)

2018 International Energy Conservation Code

Revise as follows:

R403.1.2 (IRC N1103.1.2) Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation to only those times when:
1. The vapor compression cycle cannot provide the necessary heating energy to satisfy the heat pump compressor can meet the heating load.
2. The heat pump is operating in defrost mode.
3. The vapor compression cycle malfunctions, or
4. The thermostat malfunctions.

Reason: This proposal updates this requirement to account for real world operation of heat pumps. There are times when supplemental heat will be needed to be used apart from defrost operation. The reasons for the additional exceptions are as follows:
Vapor Compression cycle malfunction. If the compressor or reversing valve or metering device (such as a capillary tube or thermal expansion valve) is not working properly, the current requirements do not allow supplemental heat to be used. As a result, the space will not be conditioned, and in extreme cases where the compressor is not fixed, the temperatures could fall to levels where unsafe situations (such as pipes freezing) could develop.

Thermostat malfunction. If the thermostat is not working properly, the current requirements do not allow supplemental heat to be used. As a result, the space may not be conditioned, and when the thermostat is repaired, supplemental heat may be needed in conjunction with the compressor and fan motor to get the space back to its programmed temperature in a short period of time.

It should also be noted that the national energy efficiency standards for residential heat pumps have increased significantly over the past 25 years, and will increase again in January, 2023. Also, with more heat pumps having "smart" technology, the system owner can be notified immediately on a smart phone or computer if such a malfunction is occurring, which will limit such operation.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This will not increase (or decrease) the cost of construction, as the exceptions shown are already aspects of current heat pump control strategies and will not increase the cost to purchase, install, or operate a heat pump.

Proposal # 4979
CE117-19

2018 International Energy Conservation Code

Revise as follows:

C403.4.1.4 Heated or cooled vestibules (Mandatory). The heating system for heated vestibules and air curtains with integral heating shall be provided with controls configured to shut off the source of heating when the outdoor air temperature is greater than 45°F (7°C) 60°F (16°C). Vestibule heating and cooling systems shall be controlled by a thermostat located in the vestibule configured to limit heating to a temperature not greater than 60°F (16°C) 68°F (20°C) and cooling to a temperature not less than 85°F (29°C).

Exception: Control of heating or cooling provided by site-recovered energy or transfer air that would otherwise be exhausted.

Reason: Why is the proposed code change needed?

Heated vestibules are important in Cold weather climates to provide the thermal separation between the indoors and outdoors. Shutting off the heat source at 45°F will mean that the vestibule temperature will drop to 45°F, which will cause problems with cold air entering the building when the vestibule doors are opened. These problems include causing cold conditions at reception areas of commercial office buildings.

Increasing the allowable controlled temperature within the vestibule provides a better thermal buffer when the doors are opened. With cold outdoor air conditions, the vestibules cool off very quickly when the doors are opened, especially if there is a wind blowing into the vestibule. Problems associated with vestibule in the winter are too low of temperatures and the proposed limitations will only make the problems greater.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code already requires the controls to operate the heating and cooling systems for vestibules so there are no additional materials or installation labor necessary. This is simply a change in thermostat set points to maintain reception areas and entrance areas to office buildings at a warmer temperature for those individuals working at or near building entrances. There will be a energy savings in colder climates because keeping this area at a warmer more comfortable temperature, negates the need for the individuals to place a small electric inefficient heater under the desk to stay warm. Less use of portable space heaters in a building will also reduce fire hazards.

Proposal # 5123
CE118-19
IECC: C403.4.1.4

Proponent: Ellen Eggerton, City of Alexandria, representing self (ellen.eggerton@alexandriava.gov)

2018 International Energy Conservation Code

Revise as follows:

C403.4.1.4 Heated or cooled vestibules (Mandatory). The heating system for heated vestibules and air curtains with integral heating shall be provided with controls configured to shut off the source of heating when the outdoor air temperature is greater than 45°F (7°C). Vestibule heating and cooling systems shall be controlled by a thermostat located in the vestibule configured to limit heating to a temperature not greater than 60°F (16°C) and cooling to a temperature not less than 85°F (29°C). Mechanical cooling of vestibules is prohibited.

Exception: Control of heating or cooling provided by site-recovered energy or transfer air that would otherwise be exhausted.

Reason: Vestibules are a transition from conditioned to unconditioned space. Vestibules only require freeze protection for sprinklers and maintaining door operations during cold weather. Cooling vestibules wastes cooling energy each time the outside outside doors open. Better designed vestibules minimize the movement of air into the building by a design where the outside door starts to close as the inside door is opening other than during high traffic times or has a change in direction to reduce the flow of air infiltration of unconditioned air.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change will not increase construction cost as thermostatic controls are already required. This change will reduce operating energy consumption.

Proposal # 5422

CE118-19
CE119-19

IECC: C403.4.2.1

**Proponent:** donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

**2018 International Energy Conservation Code**

Revise as follows:

**C403.4.2.1 Thermostatic setback (Mandatory).** Thermostatic setback controls shall be configured to set back or temporarily operate the system to maintain zone temperatures down to 55°F (13°C) or up to 85°F (29°C). Heating systems shall be configured with controls to automatically restart and temporarily operate the systems to maintain setback zone temperatures above the heating setpoint adjustable down to 55°F (13°C). Cooling systems shall be configured with controls to automatically restart and temporarily operate the system to maintain setback zone temperatures below a cooling setpoint adjustable up to 85°F (29°C) or to prevent excessive space humidity levels.

**Exceptions:**

1. Radiant floor and radiant ceiling heating systems.
2. Spaces where constant temperature conditions must be maintained.

**Reason:** Why is the proposed code change needed?

It clarifies the heating conditions and cooling conditions. It is important to control the humidity level in the summer. Radiant heating systems should not be reset because their thermal mass causes them to change conditions very slowly, which can be problematic towards maintaining comfort conditions in the occupied spaces.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The code already requires the set back thermostat controls, so there are no additional materials or installation labor necessary. This code change simply clarifies heating and cooling conditions and control humidity levels in buildings. Latent Loads on a building will cause the systems to operate poorly resulting in more energy to reduce moist loads that make the building more comfortable for its occupants.

Proposal # 5067
**CE120-19**

IECC: C403.4.2.3

**Proponent:** Nicholas O'Neil, NW Energy Codes Group, representing NW Energy Codes Group  
(noneil@energy350.com)

**2018 International Energy Conservation Code**

Revise as follows:

C403.4.2.3 **Automatic start and stop (Mandatory).** Automatic start and stop controls shall be provided for each HVAC system. The automatic start controls shall be configured to automatically adjust the daily start time of the HVAC system in order to bring each space to the desired occupied temperature immediately prior to scheduled occupancy. The automatic stop controls shall be configured to reduce the HVAC system's heating temperature setpoint and increase the cooling temperature setpoint by at least 2°F before scheduled unoccupied periods based upon the thermal lag and acceptable drift in space temperature that is within comfort limits.

**Reason:** The IECC currently requires Automatic Start but neglects to include Automatic Stop controls which can further reduce energy use with minimal cost. This feature has been commonplace on DDC and BMS control systems for many years and is now becoming commonplace with standalone building thermostats as well, making this feature a market-ready solution to further reduce energy costs. The primary economic impact is a reduction in energy consumption through the use of existing building controls. There is a direct benefit to the building owner, tenants, and businesses via a reduction in energy costs related to reduced cooling and heating loads.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Systems that include Automatic Start are capable of implementing Automatic Stop as well. The financial impact on construction is effectively zero as the additional labor to program the Automatic Stop control algorithm into a BMS or DDC system that is already required to have Automatic Start is minimal.
2018 International Energy Conservation Code

C403.1.1 Calculation of heating and cooling loads. Design loads associated with heating, ventilating and air conditioning of the building shall be determined in accordance with ANSI/ASHRAE/ACCA Standard 183 or by an approved equivalent computational procedure using the design parameters specified in Chapter 3. Heating and cooling loads shall be adjusted to account for load reductions that are achieved where energy recovery systems are utilized in the HVAC system in accordance with the ASHRAE HVAC Systems and Equipment Handbook by an approved equivalent computational procedure.

Revise as follows:

C403.4.3.3.2 Heat rejection. The following shall apply to hydronic water loop heat pump systems in Climate Zones 3 through 8:

1. Where a closed-circuit cooling tower is used directly in the heat pump loop, either an automatic valve shall be installed to bypass the flow of water around the closed-circuit cooling tower, except for any flow necessary for freeze protection, or low-leakage positive-closure dampers shall be provided.

2. Where an open-circuit cooling tower is used directly in the heat pump loop, an automatic valve shall be installed to bypass all heat pump water flow around the open-circuit cooling tower.

3. Where an open-circuit or closed-circuit cooling tower is used in conjunction with a separate heat exchanger to isolate the open-circuit cooling tower from the heat pump loop, heat loss shall be controlled by shutting down the circulation pump on the cooling tower loop.

Exception: Where it can be demonstrated that a heat pump system will be required to reject heat throughout the year.

Reason: There may be installations where a closed-circuit cooling tower is used for the described purposes. The circulation pumps for the closed-circuit cooling tower should be treated the same as for the open-circuit cooling tower

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal may increase costs when closed circuit towers are used in conjunction with a separate heat exchanger, which is happening currently every day. We believe the intent of the original language was to include requirements for both open and closed-circuit towers but adding closed circuit was mistakenly left out of the code language. It makes sense to have the language for both open and closed in this specific case or use.

Proposal # 5122
2018 International Energy Conservation Code

Revise as follows:

C403.4.3.3 Two-position valve. Each hydronic heat pump on the hydronic system having a total pump system power exceeding 10 hp (7.5 kW) shall have a two-position automatic valve interlocked to shut off the water flow when the compressor is off.

Reason: 1. Reason Why is the proposed code change needed?
The two position valve needs to be an automatic valve to shut off when the heat pump compressor is off. It is also important to interlock with the compressor so that the compressor does not run unless the valve is open. This wording makes this section essentially the same as Section C403.4.3.3.

2. Why is the proposed code change a reasonable solution?
Because it is the correct method to install automatic valves in heat pump systems.

If the interlock is not installed correctly, there will be problems with heat pumps tripping out.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The two position valve is already required by the code. Typically, these valves are automatic so in most cases, no additional materials or installation labor are necessary. This proposal simply clarifies that they should be automatic to provide for the intended operation. These valves save on operational costs of the system by not running heat pumps when the pumps not needed. Proper interlocking reduces excess wear and tear on the pumps which adds longevity to the system.

Proposal # 5066
CE123-19

IECC: C403.5

Proponent: Joseph Hill, NYSDOS, representing NYSDOS (Joseph.Hill@dos.ny.gov); John Addario, New York State Department of State, representing New York State Department of State (john.addario@dos.ny.gov); Gina Bocra, representing New York City Department of Buildings (gbocra@buildings.nyc.gov)

2018 International Energy Conservation Code

Revise as follows:

C403.5 Economizers (Prescriptive). Economizers shall comply with Sections C403.5.1 through C403.5.5. An air or water economizer shall be provided for the following cooling systems:

1. Chilled water systems with a total cooling capacity, less cooling capacity provided with air economizers, as specified in Table C403.5(1).
2. Individual fan systems with cooling capacity greater than or equal to 54,000 Btu/h (15.8 kW) in buildings serving other than a Group R occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 300,000 Btu/h (88 kW), whichever is greater.
3. Individual fan systems with cooling capacity greater than or equal to 270,000 Btu/h (79.1 kW) in buildings serving Group R occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 1,500,000 Btu/h (440 kW), whichever is greater.

Exceptions: Economizers are not required for the following systems.

1. Individual fan systems not served by chilled water for buildings located in Climate Zones 1A and 1B.
2. Where more than 25 percent of the air designed to be supplied by the system is to spaces that are designed to be humidified above 35°F (1.7°C) dew-point temperature to satisfy process needs.
3. Systems expected to operate less than 20 hours per week.
4. Systems serving supermarket areas with open refrigerated casework.
5. Where the cooling efficiency is greater than or equal to the efficiency requirements in Table C403.5(2).
6. Systems that include a heat recovery system in accordance with Section C403.9.5.

Reason: This change more correctly represents the intent of the code, which is specifically, the occupancy served by economizers.

Bibliography: 2018 IECC

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a clarification only and will not affect the requirements of the energy code.
2018 International Energy Conservation Code

Revise as follows:

**C403.5 Economizers (Prescriptive).** Economizers shall comply with Sections C403.5.1 through C403.5.5. An air or water economizer shall be provided for the following cooling systems:

1. Chilled water systems with a total cooling capacity, less cooling capacity provided with air economizers, as specified in Table C403.5(1).
2. Individual fan systems with cooling capacity greater than or equal to 54,000 Btu/h (15.8 kW) in buildings having other than a *Group R* occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 300,000 Btu/h (88 kW), whichever is greater.
3. Individual fan systems with cooling capacity greater than or equal to 270,000 Btu/h (79.1 kW) in buildings having a *Group R* occupancy. The total supply capacity of all fan cooling units not provided with economizers shall not exceed 20 percent of the total supply capacity of all fan cooling units in the building or 1,500,000 Btu/h (440 kW), whichever is greater.

**Exceptions:** Economizers are not required for the following systems.

1. Individual fan systems not served by chilled water for buildings located in *Climate Zones* 1A and 1B.
2. Where more than 25 percent of the air designed to be supplied by the system is to spaces that are designed to be humidified above 35°F (1.7°C) dew-point temperature to satisfy process needs.
3. Systems expected to operate less than 20 hours per week.
4. Systems serving supermarket areas with open refrigerated casework.
5. Where the cooling efficiency is greater than or equal to the efficiency requirements in Table C403.5(2).
6. Systems that include a heat recovery system in accordance with Section C403.9.5.
7. VRF systems installed with a dedicated outdoor air system.

**Reason:** VRF (variable refrigerant flow) systems are unique in that they rely on the heating and cooling of the air within a room of space. There is no massive installation of ducts to move air through a central air handling system. Outside air is provided by a dedicated outside air (DOA) system. This type of heating and cooling system does not lend itself to having an economizer. The DOA system would have to be completely oversized in order to accomplish cooling with outside air. That defeats the purpose of this highly efficient heating and cooling system.

An analysis was done comparing a VRF system with a DOA system to a typical rooftop air handling unit having an economizer cycle. The two areas of the country analyzed were Chicago and Houston. The cooling energy use was compared since economizers provide cooling with outside air. The VRF with DOA used 45.5% less energy to cool a building in Chicago. For the same building in Houston, the VRF with DOA used 32.9% less energy than a rooftop unit.

This proves that a VRF system with a DOA system is more efficient than a standard rooftop unit with an...
economizer cycle. The code should be modified to recognize this energy savings.

Cost Impact: The code change proposal will decrease the cost of construction
An economizer for a VRF system is very expensive since there would have to be oversizing of DOA ducts and a larger air handler for the DOA system.
CE125-19
IECC: C403.6.5, C405.6.5.1(New)

Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

Revise as follows:

C403.6.5 Supply-air temperature reset controls. Multiple-zone HVAC systems shall include controls that are capable of and configured to automatically reset the supply-air temperature in response to representative building loads, or to outdoor air temperature. The controls shall be configured to reset the supply air temperature not less than 25 percent of the difference between the design supply-air temperature and the design room air temperature. Controls that adjust the reset based on zone humidity are allowed in Climate Zones 0B, 1B, 2B, 3B, 3C and 4 through 8. HVAC zones that are expected to experience relatively constant loads, shall have maximum airflow designed to accommodate the fully reset supply air temperature.

Exceptions:

1. Systems that prevent reheating, recooling or mixing of heated and cooled supply air.
2. Seventy-five percent of the energy for reheating is from site-recovered or site-solar energy sources.
3. Systems in Climate Zones with peak supply air quantities of 300 cfm (142 L/s) or less. 0A, 1A, and 3A with less than 3000 cfm (1500 L/s) of design outside air.
4. Systems in Climate Zone 2A with less than 10,000 cfm (5000 L/s) of design outside air.
5. Systems in Climate Zones 0A, 1A, 2A, and 3A with not less than 80 percent outside air and employing exhaust air energy recovery complying with Section C403.7.4.

Add new text as follows:

C403.6.5.1 Dehumidification Control Interaction. In Climate Zones 0A, 1A, 2A, and 3A, the system design shall allow supply air temperature reset while dehumidification is provided. When dehumidification control is active, air economizers shall be locked out.

Reason: HVAC systems with simultaneous heating and cooling require supply air temperature (SAT) reset. However, in climate zones 0A through 3A the SAT reset is likely to be overridden during dehumidification conditions. In these climate zones, several system types can successfully dehumidify the outside air while still providing SAT reset and reducing reheat energy use. By providing specific requirements related to dehumidification control interaction, the requirement for concurrent SAT reset is clarified.

Supply temperature reset saves significant heating energy in VAV reheat systems in high outside air systems, and that savings is higher in climate zone 3A than 2A, 1A and 0A. Separately dehumidifying the outside air reduces the total volume of air that must be cooled, significantly reducing cooling energy use in all the warm and humid climate zones.

An investigation using EnergyPlus of a system with a separate outside air coil for dehumidification for buildings with both 50% and 10% outside air using dual-max controlled VAV reheat boxes was conducted. It found that this approach was cost effective at or above 3000 cfm of outside air in climate zones 0A, 1A, and 3A. In climate zone 2A, cost effectiveness was found for systems with 10,000 cfm or more of outside air. In all but climate zone 2A both the low and high outside air cases were cost effective at or above 3000 cfm of outside air. In climate zone 2A, the low cfm case had a longer payback and did not meet the cost effective threshold at 3000 cfm, so the airflow threshold was increased for climate zone 2A to 10,000 cfm. The exception for zones with...
less than 300 cfm (142 L/s) was removed, as costs relate to the main system outside airflow, not the zone airflow.

While the system with a separate outside air cooling coil proved cost effective, there are other allowed systems that may have lower costs that produce similar savings. These include: bypassing return air around the cooling coil, a dedicated outside air system, and series heat recovery. The revisions proposed improve coordination with ASHRAE Standard 90.1.

**Bibliography:** Addendum *ap* to ASHRAE standard 90.1-2016.

**Cost Impact:** The code change proposal will increase the cost of construction
The code change proposal may increase the cost of construction where a bypass or separate outside air cooling coil is added. An analysis found that the proposed changes in addendum *ap* to ASHRAE standard 90.1-2016—clearly requiring SAT reset in more climate zones—would be cost effective in line with the exceptions provided.

Proposal # 4916

CE125-19
CE126-19

IECC: C403.6.9

Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

Revise as follows:

C403.6.9 Static pressure sensor location. Static pressure sensors used to control VAV fans shall be located such that the controller setpoint is not greater than 1.2 inches w.c. (299 Pa), except for systems with zone reset control complying with Section C403.6.8, Setpoints for direct digital control. Sensors shall be located in a position so the controller setpoint is optimized to maintain the minimum static pressure required for system operation throughout its range, Where this results in one or more sensors being located downstream of major duct splits, not less than one sensor shall be located on each major branch to ensure that static pressure can be maintained in each branch.

Reason: Determining where the system pressure does not exceed 1.2 inches could be difficult. When Section C403.6.9 is used, the setpoint is continually optimized, meaning that determining where the 1.2 inches is not exceeded becomes unnecessary.

Cost Impact: The code change proposal will decrease the cost of construction. Where the system designer chooses a direct digital control system for control of VAVs, sensors are already an integral part of the system. Therefore, no additional materials or installation labor are necessary. The proposal simply clarifies the location for those sensors. The continual optimization of static pressure on the system reduces the energy usage of the building.

Proposal # 5115
CE127-19
IECC: C403.7.1

Proponent: Nicholas O'Neil, NW Energy Codes Group, representing NW Energy Codes Group (noneil@energy350.com)

2018 International Energy Conservation Code

Revise as follows:

C403.7.1 Demand control ventilation (Mandatory). Demand control ventilation (DCV) shall be provided for all single-zone systems required to comply with Sections C403.5 through 403.5.3 and spaces larger than 500 square feet (46.5 m²) and with an average occupant load of 25 people or greater per 1,000 square feet (93 m²) of floor area, as established in Table 403.3.1.1 of the International Mechanical Code, and served by systems with one or more of the following:

1. An air-side economizer.
2. Automatic modulating control of the outdoor air damper.
3. A design outdoor airflow greater than 3,000 cfm (1416 L/s).

Exceptions:

1. Systems with energy recovery complying with Section C403.7.4.
2. Multiple-zone systems without direct digital control of individual zones communicating with a central control panel.
3. Multiple-zone systems with a design outdoor airflow less than 1,200 cfm (566 L/s).
4. Spaces where the supply airflow rate minus any makeup or outgoing transfer air requirement is less than 1,200 cfm (566 L/s).
5. Ventilation provided only for process loads.

Reason: Many spaces are over-ventilated due to design professionals establishing ventilation rates based on peak design conditions that rarely exist on a daily basis. Substantial energy savings can be obtained even in low-occupancy areas through the implementation of DCV. CO₂ sensor costs have fallen in recent years making DCV on smaller sized units that already require economizers, (and therefore already have modulating dampers) more cost-effective than they have been in the past.

Cost Impact: The code change proposal will increase the cost of construction. A single CO₂ sensor in the return air duct of a single zone system is expected to cost less than $300 and provides assurance that indoor air quality in smaller spaces will be maintained to safe CO₂ levels. Note that the requirement for installing DCV is only on units that are already required to have an economizer installed, which drastically reduces the cost of implementing DCV.
CE128-19

IECC: C403.7.1

Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

Revise as follows:

C403.7.1 Demand control ventilation (Mandatory). Demand control ventilation (DCV) shall be provided for spaces larger than 500 square feet (46.5 m²) and with an average occupant load of 25 people or greater per 1,000 square feet (93 m²) of floor area, as established in Table 403.3.1.1 of the International Mechanical Code, and served by systems with one or more of the following:

1. An air-side economizer.
2. Automatic modulating control of the outdoor air damper.
3. A design outdoor airflow greater than 3,000 cfm (1416 L/s).

Exceptions:

1. Systems with energy recovery complying with Section C403.7.4.
2. Multiple-zone systems without direct digital control of individual zones communicating with a central control panel.
3. Systems with a design outdoor airflow less than 1,200 cfm (566 L/s).
4. Spaces where more than 75 percent of the supply airflow rate minus any makeup or outgoing transfer air requirement is less than 1,200 cfm (566 L/s). Space design outdoor airflow is required for makeup air that is exhausted from the space or transfer air that is required for makeup air that is exhausted from other spaces.
5. Spaces with one of the following occupancy classifications as defined in Table 403.3.1.1 of the International Mechanical Code: correctional cells, education laboratories, barber, beauty and nail salons, and bowling alley seating areas.

5. Ventilation provided only for process loads.

Reason: The revisions to the DCV exceptions improve coordination with ASHRAE Standard 90.1-2013 and later. Based on improved availability of DCV controls at lower costs, the outdoor airflow exception was reduced from 1,200 cfm (566 L/s) to 750 cfm (375 L/s). The transfer air exception was changed from a fixed outside airflow amount to a percentage of outdoor air, to allow exceptions where the DCV control implementation would be difficult due to the large percentage of transfer or makeup air. The exception for ventilation for process loads would be covered by the percentage makeup air exception, so it was removed as redundant. In conjunction with the reduction of excepted spaces, certain spaces were identified where DCV would simply not work—bowling alley seating areas—or would not be appropriate to maintain adequate indoor air quality.

Cost Impact: The code change proposal will increase the cost of construction. The code change proposal will increase the cost of construction in cases where systems would have been exempt under the old exceptions; however, this is in the context of reduced cost of DCV controls as a result of more widespread use. In certain cases with a high percentage of makeup air or transfer air, the cost of construction will be reduced. An analysis found that the proposed changes in addendum as to ASHRAE standard 90.1-2010—requiring DCV in more spaces—would be cost effective in all climate zones.
CE129-19
IECC: C403.7.2

Proponent: Nicholas O'Neil, Energy 350, representing Energy 350 (noneil@energy350.com)

2018 International Energy Conservation Code

Revise as follows:

C403.7.2 Enclosed parking garage ventilation controls (Mandatory). Enclosed parking garages used for storing or handling automobiles operating under their own power shall employ contamination-sensing devices (carbon monoxide detectors applied in conjunction with nitrogen dioxide detectors) and automatic controls configured to stage fans or modulate fan average airflow rates to 50 percent or less of design capacity, or intermittently operate fans less than 20 percent of the occupied time or as required to maintain acceptable contaminant levels in accordance with International Mechanical Code provisions. Failure of contamination-sensing devices shall cause the exhaust fans to operate continuously at design airflow.

Exceptions:

1. Garages with a total exhaust capacity less than 22,800,000 cfm (40,620,377 L/s) with ventilation systems that do not utilize heating or mechanical cooling and use occupant sensors to activate the full required ventilation rate.
2. Garages that have a garage area to ventilation system motor nameplate power ratio that exceeds 1125 cfm/hp (710 L/s/kW) and do not utilize heating or mechanical cooling.

Reason: The current threshold for exempting parking ventilation controls ignores a substantial percentage of the parking garage market that could benefit from reduced fan ventilation during times of low (or no) occupancy. The cost of fan system controls and sensors has fallen in recent years making ventilation controls on smaller sized garages more cost-effective than they have been in the past.

Cost Impact: The code change proposal will increase the cost of construction.

The primary components required are sensors, controllers and fan variable frequency drives (VFDs). The cost for implementing this code requirement is estimated at $400 per 1,000 square feet of parking garage, or $0.40 per square foot. Additionally, the payback for this code proposal is less than 5 years and will be faster for larger garage sizes.
CE130-19

Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

SECTION C403 BUILDING MECHANICAL SYSTEMS

C403.7.2 Enclosed parking garage ventilation controls (Mandatory). Enclosed parking garages used for storing or handling automobiles operating under their own power shall employ contamination-sensing devices and automatic controls configured to stage fans or modulate fan average airflow rates to 50 percent or less of design capacity, or intermittently operate fans less than 20 percent of the occupied time or as required to maintain acceptable contaminant levels in accordance with International Mechanical Code provisions. Failure of contamination-sensing devices shall cause the exhaust fans to operate continuously at design airflow.

Exceptions:

1. Garages with a total exhaust capacity less than 22,500 cfm (10 620 L/s) with ventilation systems that do not utilize heating or mechanical cooling.
2. Garages that have a garage area to ventilation system motor nameplate power ratio that exceeds 1125 cfm/hp (710 L/s/kW) and do not utilize heating or mechanical cooling.

Add new text as follows:

403.7.2.1 Enclosed parking garages. Mechanical ventilation systems for enclosed parking garages shall automatically operate upon detection of certain gases. Parking garages must be equipped with carbon monoxide (CO) detection sensors that will activate the mechanical ventilation system upon detection of a CO level of 25 part per million (ppm) or greater. Parking garages must also be equipped with nitrogen dioxide (NO2) detection sensors that will activate the mechanical ventilation system upon detection of a NO2 level of 3 ppm or greater. Such detectors shall be listed in accordance with UL 2075 and installed in accordance with their listing and the manufacturers' instructions.

403.7.2.2 Minimum exhaust.
The mechanical ventilation system shall provide a minimum exhaust rate of 0.75 cfm per square foot (0.0038 m³/s-m²) of the floor area served.

403.7.2.3 Occupied spaces accessory to public garages. Connecting offices, elevator lobbies, waiting rooms, ticket booths and similar uses that are accessory to a public garage shall be maintained at a positive pressure and shall be provided with ventilation in accordance with Section 403.3.1.

Reason: Why is the proposed code change needed?
Experience has shown that it is unnecessary to continuously ventilate parking garages to maintain safe air quality conditions within, especially during periods of minimal or no vehicular activity, such as nights or weekends. Requiring continuous ventilation will create temperature conditions in the garage that are the same as the outdoors, which is not always desirable, especially during very cold outdoor conditions. Requiring CO and NO2 sensors and control maintains safe conditions within the enclosed parking garages even with vehicular activity.

The proposed revisions are essentially the same as the current Minnesota requirements, which have been in
place for a long time and have worked well. Some language is clarified, and the UL standards for the CO and NO₂ sensors was added. It is important to identify the concentrations of these gases where the ventilation system is activated because the sensors have different settings.

Our existing code identifies the CO sensor requirements for parking garages containing gas fueled vehicles and NO₂ sensor requirements for garages containing diesel fueled vehicles. This proposed change requires both types of sensors to be required in all enclosed parking garages because there is no reasonable method of separating out garage service, and diesel vehicles are more common.

Why is the proposed code change a reasonable solution?

It brings forward and updates the existing requirements for enclosed parking garages.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code already requires the detection sensors therefore, no additional materials or installation labor are necessary. The proposal simply clarifies the necessary details about the sensor contaminate types and activation thresholds.
C403.7.4 Energy recovery ventilation systems (Mandatory). Where the supply airflow rate of a fan system exceeds the values specified in Tables C403.7.4(1) and C403.7.4(2), the system shall include an energy recovery system. The energy recovery system shall be configured to provide a change in the enthalpy of the outdoor air supply of not less than 50 percent of the difference between the outdoor air and return air enthalpies, at design conditions. Where an air economizer is required, the energy recovery system shall include a bypass or controls that permit operation of the economizer as required by Section C403.5.

Exception: An energy recovery ventilation system shall not be required in any of the following conditions:

1. Where energy recovery systems are prohibited by the International Mechanical Code.
2. Laboratory fume hood systems that include not fewer than one of the following features:
   2.1. Variable-air-volume hood exhaust and room supply systems configured to reduce exhaust and makeup air volume to 50 percent or less of design values.
   2.2. Direct makeup (auxiliary) air supply equal to or greater than 75 percent of the exhaust rate, heated not warmer than 2°F (1.1°C) above room setpoint, cooled to not cooler than 3°F (1.7°C) below room setpoint, with no humidification added, and no simultaneous heating and cooling used for dehumidification control.
3. Systems serving spaces that are heated to less than 60°F (15.5°C) and that are not cooled.
4. Where more than 60 percent of the outdoor heating energy is provided from site-recovered or site-solar energy.
5. Heating energy recovery in Climate Zones 1 and 2.
6. Cooling energy recovery in Climate Zones 3C, 4C, 5B, 5C, 6B, 7 and 8.
7. Systems requiring dehumidification that employ energy recovery in series with the cooling coil.
8. Where the largest source of air exhausted at a single location at the building exterior is less than 75 percent of the design outdoor air flow rate.
9. Systems expected to operate less than 20 hours per week at the outdoor air percentage covered by Table C403.7.4(1).
10. Systems exhausting toxic, flammable, paint or corrosive fumes or dust.
11. Commercial kitchen hoods used for collecting and removing grease vapors and smoke.
12. Individual ventilation systems that serve an individual dwelling unit or sleeping unit.

Reason: This code change proposal increases the ease of use of the Code without changing the de facto requirements of this Mandatory provision. Individual ventilation systems that serve individual dwelling units are already not required to use Energy recovery ventilation systems based on the tables below. The math and logic to arrive at that answer can be difficult and confusing however. This exception then just pre-states when it already a reality is such a way to save the user of the Code time and effort in understanding and implementing to Code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This code change proposal simplifies the understanding and implementation of Code without changing the underlying requirement.
Proponent: Mike Moore, Newport Ventures, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

ENTHALPY RECOVERY RATIO. Change in the enthalpy of the outdoor air supply divided by the difference between the outdoor air and entering exhaust air enthalpy, expressed as a percentage.

Revise as follows:

C403.7.4 Energy recovery ventilation systems (Mandatory). Where the supply airflow rate of a fan system exceeds the values specified in Tables C403.7.4(1) and C403.7.4(2), the system shall include an energy recovery system. The energy recovery system shall be configured to provide a change in the enthalpy of the outdoor air supply of not less than 50 percent of the difference between the outdoor air and return air enthalpies, at design conditions. Where an air economizer is required, the energy recovery system shall include a bypass or controls that permit operation of the economizer as required by Section C403.5. Energy recovery ventilation systems shall comply with Sections C403.7.4.1 and Section C403.7.4.2.

Exception: An energy recovery ventilation system shall not be required in any of the following conditions:

- Where energy recovery systems are prohibited by the International Mechanical Code.
- Laboratory fume hood systems that include not fewer than one of the following features:
  1. Variable air volume hood exhaust and room supply systems configured to reduce exhaust and makeup air volume to 50 percent or less of design values.
  2. Direct makeup (auxiliary) air supply equal to or greater than 75 percent of the exhaust rate, heated not warmer than 2°F (1.1°C) above room setpoint, cooled to not cooler than 3°F (1.7°C) below room setpoint, with no humidification added, and no simultaneous heating and cooling used for dehumidification control.
- Systems serving spaces that are heated to less than 60°F (15.5°C) and that are not cooled.
- Where more than 60 percent of the outdoor heating energy is provided from site-recovered or site-solar energy.
- Heating energy recovery in Climate Zones 1 and 2.
- Cooling energy recovery in Climate Zones 3C, 4C, 5B, 5C, 6B, 7 and 8.
- Systems requiring dehumidification that employ energy recovery in series with the cooling coil.
- Where the largest source of air exhausted at a single location at the building exterior is less than 75 percent of the design outdoor air flow rate.
- Systems expected to operate less than 20 hours per week at the outdoor air percentage covered by Table C403.7.4(1).
- Systems exhausting toxic, flammable, paint or corrosive fumes or dust.
- Commercial kitchen hoods used for collecting and removing grease vapors and smoke.

Add new text as follows:
C403.7.4.1 Nontransient dwelling units (Prescriptive). Nontransient dwelling units shall be provided with outdoor air energy recovery ventilation systems with an enthalpy recovery ratio of not less than 50% at cooling design condition and not less than 60% at heating design condition.

Exceptions:

1. Nontransient dwelling units in Climate Zone 3C.

2. Nontransient dwelling units with no more than 500 ft² of conditioned floor area in Climate Zones 0, 1, 2, 3, 4C, and 5C.

3. Enthalpy recovery ratio requirements at heating design condition in Climate Zones 0, 1, and 2.

4. Enthalpy recovery ratio requirements at cooling design condition in Climate Zones 4, 5, 6, 7, and 8.

C403.7.3.2 Spaces other than nontransient dwelling units (Mandatory). Where the supply airflow rate of a fan system serving a space other than a nontransient dwelling unit exceeds the values specified in Tables C403.7.4(1) and C403.7.4(2), the system shall include an energy recovery system. The energy recovery system shall provide an enthalpy recovery ratio of not less than 50 percent at design conditions. Where an air economizer is required, the energy recovery system shall include a bypass or controls that permit operation of the economizer as required by Section C403.5.

Exception: An energy recovery ventilation system shall not be required in any of the following conditions:

1. Where energy recovery systems are prohibited by the International Mechanical Code.
2. Laboratory fume hood systems that include not fewer than one of the following features:
   2.1. Variable-air-volume hood exhaust and room supply systems configured to reduce exhaust and makeup air volume to 50 percent or less of design values.
   2.2. Direct makeup (auxiliary) air supply equal to or greater than 75 percent of the exhaust rate, heated not warmer than 2°F (1.1°C) above room setpoint, cooled to not cooler than 3°F (1.7°C) below room setpoint, with no humidification added, and no simultaneous heating and cooling used for dehumidification control.
3. Systems serving spaces that are heated to less than 60°F (15.5°C) and that are not cooled.
4. Where more than 60 percent of the outdoor heating energy is provided from site-recovered or site-solar energy.
5. Enthalpy recovery ratio requirements in Climate Zones 1 and 2.
6. Enthalpy recovery ratio requirements in Climate Zones 3C, 4C, 5B, 5C, 6B, 7 and 8.
7. Systems requiring dehumidification that employ energy recovery in series with the cooling coil.
8. Where the largest source of air exhausted at a single location at the building exterior is less than 75 percent of the design outdoor air flow rate.
9. Systems expected to operate less than 20 hours per week at the outdoor air percentage covered by Table C403.7.4(1).
10. Systems exhausting toxic, flammable, paint or corrosive fumes or dust.
11. Commercial kitchen hoods used for collecting and removing grease vapors and smoke.

Reason: This proposal aligns ASHRAE 90.1 and the IECC requirements for energy recovery ventilation systems by:
1) Changing the specification of heat and energy recovery ventilation systems (H/ERVs) for nontransient* dwelling units from Mandatory to Prescriptive, and
2) Adding minimum prescriptive path requirements for nontransient* dwelling unit H/ERVs in the prescriptive path, where cost effective.

*Based on the IBC definition of “transient”, “nontransient” dwelling units are those that are occupied for more than 30 days; this term carries the same meaning as used in Section 310 of the 2018 IBC.

Prior to the publication of addendum ay to ASHRAE 90.1-2017, both 90.1 and IECC Section C403.7.4 contained energy recovery ventilation requirements that were developed without consideration given for dwelling units within the scope of 90.1 and the IECC. In an effort to develop rational energy recovery ventilation requirements for nontransient dwelling units, 90.1 considered building energy simulations that were conducted on a nominal 1000 ft², 2-bedroom apartment in compliance with the prescriptive path of 90.1 across all climate zones. Four ventilation systems were evaluated for outdoor air: exhaust-only, dedicated supply, central fan integrated supply, and balanced with energy recovery. Ventilation rates were set in accordance with the minimum permitted by ASHRAE 62.2 (comparable to 2018 IMC minimum requirements for mechanical ventilation of high-rise dwelling units). Simulations were run in EnergyPlus. A list of detailed inputs and outputs is also provided in a separate Excel file, with a narrative available in a PowerPoint document. The simulations and accompanying economic analysis resulted in a very favorable scalar ratio (ASHRAE 90.1’s metric for cost effectiveness**) for dwelling unit energy recovery ventilation systems in all climate zones except for 3C for typical dwelling units and except for climate zones 0B, 1, 2, 3, 4C, and 5C for small dwelling units (i.e., no more than 500 ft²). Additionally, the proposal exempts all dwelling units in climate zones 0, 1, 2, and 3C from heating energy recovery requirements and climate zones 3C, 4, 5, 6, 7, and 8 from cooling energy recovery requirements based on insignificant energy savings. This proposal to the IECC mirrors what was vetted and developed over several months by ASHRAE Technical Committee TC5.5 prior to submitting to the 90.1 Mechanical Subcommittee and ultimately approved as addendum ay by the full 90.1 committee.

**A “favorable scalar” is 12.5 or less for heat exchangers with an expected life of 15 years. The economic analysis behind 90.1 addendum ay and this proposal showed an average scalar of 2.9 for the 1008 ft² apartment across all climate zones, and an average of 9.3 for the 500 ft² apartment across all climate zones but the exempted climate zones 0, 1, 2, 3, 4C, and 5C.

For an overview of ASHRAE 90.1’s economic model and the scalar method, a presentation summarizing the building energy simulations supporting ASHRAE 90.1 addendum ay and this proposal, and an Excel workbook with the building energy simulation inputs, results, and economic analysis, see this link: https://www.dropbox.com/sh/tbjpbqyz2tccqlk/AADJUnPOlwumQVCJeVGjsN0a?dl=0.

Bibliography: For an overview of ASHRAE 90.1’s economic model and the scalar method, a presentation summarizing the building energy simulations supporting ASHRAE 90.1 addendum ay and this proposal, and an Excel workbook with the building energy simulation inputs, results, and economic analysis, see this link: https://www.dropbox.com/sh/tbjpbqyz2tccqlk/AADJUnPOlwumQVCJeVGjsN0a?dl=0.

Cost Impact: The code change proposal will increase the cost of construction

By moving the requirement for nontransient dwelling unit H/ERVs from the Mandatory path to the Prescriptive path, first costs may be reduced for some projects where H/ERVs are currently mandated. For other projects that are not currently required to have H/ERVs in the prescriptive path, would not normally install H/ERVS, and for which this proposal introduces new prescriptive path requirements, the first could increase. As explained in the rationale, however, where new requirements are introduced by this proposal, they have been vetted by ASHRAE 90.1 and shown to be cost effective based on energy savings over the useful life of the equipment. A detailed explanation of costs and benefits associated with this proposal can be found with this link: https://www.dropbox.com/sh/tbjpbqyz2tccqlk/AADJUnPOlwumQVCJeVGjsN0a?dl=0.
Add new definition as follows:

**ENTHALPY RECOVERY RATIO.** Change in the enthalpy of the *outdoor air* supply divided by the difference between the *outdoor air* and entering exhaust air enthalpy, expressed as a percentage.

Add new text as follows:

**C403.7.4 Energy Recovery Systems.** Energy recovery ventilation systems shall be provided as specified in either Section 403.7.1 or 403.7.2, as applicable.

**C403.7.4.1 Nontransient dwelling units (Prescriptive).** Nontransient dwelling units shall be provided with outdoor air energy recovery ventilation systems with an enthalpy recovery ratio of not less than 50 percent at cooling design condition and not less than 60 percent at heating design condition.

**Exceptions:**

1. Nontransient dwelling units in Climate Zone 3C.
2. Nontransient dwelling units with no more than 500 square feet (46 m²) of conditioned floor area in Climate Zones 0, 1, 2, 3, 4C, and 5C.
3. Enthalpy recovery ratio requirements at heating design condition in Climate Zones 0, 1, and 2.
4. Enthalpy recovery ratio requirements at cooling design condition in Climate Zones 4, 5, 6, 7, and 8.

Revise as follows:

**C403.7.4.2 Energy recovery ventilation systems-Spaces other than nontransient dwelling units (Mandatory).** Where the supply airflow rate of a fan system serving a space other than a nontransient dwelling unit exceeds the values specified in Tables C403.7.4(1) and C403.7.4(2), the system shall include an energy recovery system. The energy recovery system shall be configured to provide a change in the enthalpy of the outdoor air supply provide an enthalpy recovery ratio of not less than 50 percent of the difference between the outdoor air and return air enthalpies, at design conditions. Where an air economizer is required, the energy recovery system shall include a bypass or controls that permit operation of the economizer as required by Section C403.5.

**Exception:** An energy recovery ventilation system shall not be required in any of the following conditions:

1. Where energy recovery systems are prohibited by the International Mechanical Code.
2. Laboratory fume hood systems that include not fewer than one of the following features:
   2.1. Variable-air-volume hood exhaust and room supply systems configured to reduce exhaust and makeup air volume to 50 percent or less of design values.
2.2. Direct makeup (auxiliary) air supply equal to or greater than 75 percent of the exhaust rate, heated not warmer than 2°F (1.1°C) above room setpoint, cooled to not cooler than 3°F (1.7°C) below room setpoint, with no humidification added, and no simultaneous heating and cooling used for dehumidification control.

3. Systems serving spaces that are heated to less than 60°F (15.5°C) and that are not cooled.

4. Where more than 60 percent of the outdoor heating energy is provided from site-recovered or site-solar energy.

5. Heating energy Enthalpy recovery ratio requirements in Climate Zones 0, 1 and 2.

6. Cooling energy Enthalpy recovery ratio requirements in Climate Zones 3C, 4C, 5B, 5C, 6B, 7 and 8.

7. Systems requiring dehumidification that employ energy recovery in series with the cooling coil.

8. Where the largest source of air exhausted at a single location at the building exterior is less than 75 percent of the design outdoor air flow rate.

9. Systems expected to operate less than 20 hours per week at the outdoor air percentage covered by Table C403.7.4(1).

10. Systems exhausting toxic, flammable, paint or corrosive fumes or dust.

11. Commercial kitchen hoods used for collecting and removing grease vapors and smoke.

Reason: This proposal aligns ASHRAE 90.1 and the IECC requirements for energy recovery ventilation systems by:

1) Changing the specification of energy recovery ventilation systems from Mandatory to Prescriptive, and

2) Adding minimum prescriptive path requirements for nontransient* dwelling unit H/ERVs in the prescriptive path, where cost effective.

*Based on the IBC definition of “transient”, “nontransient” dwelling units are those that are occupied for more than 30 days; this term carries the same meaning as used in Section 310 of the 2018 IBC.

Prior to the publication of addendum ay to ASHRAE 90.1-2017, both 90.1 and IECC Section C403.7.4 contained energy recovery ventilation requirements that were developed without consideration given for dwelling units within the scope of 90.1 and the IECC. In an effort to develop rational energy recovery ventilation requirements for nontransient dwelling units, 90.1 considered building energy simulations that were conducted on a nominal 1000 ft², 2-bedroom apartment in compliance with the prescriptive path of 90.1 across all climate zones. Four ventilation systems were evaluated for outdoor air: exhaust-only, dedicated supply, central fan integrated supply, and balanced with energy recovery. Ventilation rates were set in accordance with the minimum permitted by ASHRAE 62.2 (comparable to 2018 IMC minimum requirements for mechanical ventilation of high-rise dwelling units). Simulations were run in EnergyPlus. A list of detailed inputs and outputs is also provided in a separate Excel file, with a narrative available in a PowerPoint document. The simulations and accompanying economic analysis resulted in a very favorable scalar ratio (ASHRAE 90.1’s metric for cost effectiveness**) for dwelling unit energy recovery ventilation systems in all climate zones except for 3C for typical dwelling units and except for climate zones 0B, 1, 2, 3, 4C, and 5C for small dwelling units (i.e., no more than 500 ft²). Additionally, the proposal exempts all dwelling units in climate zones 0, 1, 2, and 3C from heating energy recovery requirements and climate zones 3C, 4, 5, 6, 7, and 8 from cooling energy recovery requirements based on insignificant savings. This proposal to the IECC mirrors what was vetted and developed over several months by ASHRAE Technical Committee TC5.5 prior to submitting to the 90.1 Mechanical Subcommittee and ultimately approved as addendum ay by the full 90.1 committee.

**A “favorable scalar” is 12.5 or less for heat exchangers with an expected life of 15 years. The economic analysis behind 90.1 addendum ay and this proposal showed an average scalar of 2.9 for the 1008 ft² apartment across all climate zones, and an average of 9.3 for the 500 ft² apartment across all climate zones but
the exempted climate zones 0, 1, 2, 3, 4C, and 5C.

For an overview of ASHRAE 90.1’s economic model and the scalar method, a presentation summarizing the building energy simulations supporting ASHRAE 90.1 addendum ay and this proposal, and an Excel workbook with the building energy simulation inputs, results, and economic analysis, see this link: https://www.dropbox.com/sh/tbjpbqyz2tccqklk/AADJUnP0lwumQVcJJeVGjsNoa?dl=0.

Bibliography: Addendum AY to 90.1-2016.

Cost Impact: The code change proposal will increase the cost of construction. By moving the requirement for H/ERVs from the Mandatory path to the Prescriptive path, first costs may be reduced for some projects. For other projects that are not currently required to have H/ERVs in the prescriptive path, would not normally install H/ERVS, and for which this proposal introduces new prescriptive path requirements, the first cost will increase. As explained in the rationale, however, where new requirements are introduced by this proposal, they have been vetted by ASHRAE 90.1 and shown to be cost effective based on energy savings over the useful life of the equipment and a favorable scalar ratio. IECC: C403.7.5 (New), TABLE C403.7.5 (New)

Proponent: Guy McMann, Jefferson County, Colorado, representing Colorado Association of Plumbing and Mechanical Officials (CAPMO) (gmcmann@jeffco.us)

2018 International Energy Conservation Code

Delete without substitution:

C403.7.5 Kitchen exhaust systems (Mandatory). Replacement air introduced directly into the exhaust hood cavity shall not be greater than 10 percent of the hood exhaust airflow rate. Conditioned supply air delivered to any space shall not exceed the greater of the following:

1. The ventilation rate required to meet the space heating or cooling load.
2. The hood exhaust flow minus the available transfer air from adjacent space where available transfer air is considered to be that portion of outdoor ventilation air not required to satisfy other exhaust needs, such as restrooms, and not required to maintain pressurization of adjacent spaces.

Where total kitchen hood exhaust airflow rate is greater than 5,000 cfm (2360 L/s), each hood shall be a factory-built commercial exhaust hood listed by a nationally recognized testing laboratory in compliance with UL 710. Each hood shall have a maximum exhaust rate as specified in Table C403.7.5 and shall comply with one of the following:

1. Not less than 50 percent of all replacement air shall be transfer air that would otherwise be exhausted.
2. Demand ventilation systems on not less than 75 percent of the exhaust air that are configured to provide not less than a 50 percent reduction in exhaust and replacement air system airflow rates, including controls necessary to modulate airflow in response to appliance operation and to maintain full capture and containment of smoke, effluent and combustion products during cooking and idle.
3. Listed energy recovery devices with a sensible heat recovery effectiveness of not less than 40 percent on not less than 50 percent of the total exhaust airflow.

Where a single hood, or hood section, is installed over appliances with different duty ratings, the maximum allowable flow rate for the hood or hood section shall be based on the requirements for the highest appliance duty rating under the hood or hood section.

**Exception:** Where not less than 75 percent of all the replacement air is transfer air that would otherwise be exhausted.

</table>

For SI: 1 cfm = 0.4719 L/s; 1 foot = 305 mm.

NA = Not Allowed.

**Reason:** These sections are inconsistent with the IMC and was never coordinated for the last two cycles. This requirement is also a job killer in that non-710 hoods over 5000 cfm can no longer be constructed where the IMC still permits it. This does nothing to help the economy whatsoever. This has created a tremendous conflict between the two codes. The unintended consequence is that it results in the inability to re-locate a non-710 hood over 5000 cfm to a new location even though it was lawfully installed at the time. What's the logic in tossing a perfectly good system and having to spend thousands of dollars to replace it. The table is already in the IMC where it belongs and not in the IECC. Yes a 710 hood moves less air than a non-listed hood but the savings will never be realized if a new system has to be employed. This will eliminate the ability to build a custom hood if a designer so chose to do so. The cost of this code section presents an unfair burden on the owners. This subject matter belongs in the IMC, not the IECC.

**Cost Impact:** The code change proposal will decrease the cost of construction
Not having to toss a perfectly good system will decrease cost.
CE135-19
IECC: SECTION C202, C403.7.6.1, C403.7.6.2

Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Revise as follows:

NETWORKED GUESTROOM CONTROL SYSTEM. A control system, accessible from the front desk or other central location associated with a Group R-1 building, that is capable of identifying the occupancy-rented and unrented status of each guestroom according to a timed schedule, and is capable of controlling HVAC in each hotel and motel guestroom separately.

C403.7.6 Automatic control of HVAC systems serving guestrooms (Mandatory). In Group R-1 buildings containing more than 50 guestrooms, each guestroom shall be provided with controls complying with the provisions of Sections C403.7.6.1 and C403.7.6.2. Card key controls comply with these requirements.

C403.7.6.1 Temperature setpoint controls. Controls shall be provided on each HVAC system that are capable of and configured with three modes of temperature control.

1. When the guest room is rented but unoccupied, the controls shall automatically raise the cooling setpoint and lower the heating setpoint by not less than 4°F (2°C) from the occupant setpoint within 30 minutes after the occupants have left the guestroom.

2. When the guest room is unrented and unoccupied, the controls shall be capable of and configured to automatically raise the cooling setpoint to not lower than 80°F (27°C) and lower the heating setpoint to not higher than 60°F (16°C) when the guestroom is unrented or has not been continuously occupied for more than 16 hours or . Unrented and unoccupied guest room mode shall be initiated within 16 hours of the guest room being continuously occupied or where a networked guestroom control system indicates that the guestroom is unrented and the guestroom is unoccupied for more than 30 minutes. A networked guestroom control system that is capable of returning the thermostat setpoints to default occupied setpoints 60 minutes prior to the time a guestroom is scheduled to be occupied is not precluded by this section. Cooling that is capable of limiting relative humidity with a setpoint not lower than 65-percent relative humidity during unoccupied periods is not precluded by this section.

3. When the guest room is occupied, HVAC set points shall return to their occupied set points once occupancy is sensed.

C403.7.6.2 Ventilation controls. Controls shall be provided on each HVAC system that are capable of and configured to automatically turn off the ventilation and exhaust fans within 30 minutes of the occupants leaving the guestroom, or isolation devices shall be provided to each guestroom that are capable of automatically shutting off the supply of outdoor air to and exhaust air from the guestroom.

Exception: Guestroom ventilation systems are not precluded from having an automatic daily pre-occupancy purge cycle that provides daily outdoor air ventilation during unrented periods at the design ventilation rate for 60 minutes, or at a rate and duration equivalent to one air change.

Reason: This addendum contains minor changes to language for clarification. Original language could be interpreted to allow room lighting and HVAC to resume after 30 minutes of unoccupied and unrented condition. Changes include:
1. The guest room temperature controls subsection is reorganized to clarify that there are three distinct modes of operation.
2. The definition of networked guest room control system is modified to be consistent with the requirements.
3. The time-out period for unoccupied indication is changed from 30 minutes to 20 minutes for consistency between HVAC and the lighting control in Section C405.2.1.1.

**Bibliography:** Addendum *k* to ASHRAE standard 90.1-2016

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The code change proposal will not increase the cost of construction. The language changes are intended to be clarifications only.
CE136-19
IECC: SECTION C202 (New), C403.8.2

Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

**FAN NAMEPLATE ELECTRICAL INPUT POWER.** The nominal electrical input power rating stamped on a fan assembly nameplate.

Revise as follows:

**C403.8.2 Motor nameplate horsepower (Mandatory).** For each fan, the fan brake horsepower shall be indicated on the construction documents and the selected motor shall be not larger than the first available motor size greater than the following:

1. For fans less than 6 bhp (4413 W), 1.5 times the fan brake horsepower.
2. For fans 6 bhp (4476 W) and larger, 1.3 times the fan brake horsepower.

Exception Exceptions:

1. Fans equipped with electronic speed control devices to vary the fan airflow as a function of load.
2. Fans with a fan nameplate electrical input power of less than .89 kW.
3. Systems complying with Section C403.8.1 fan system motor nameplate hp (Option 1).
4. Fans with motor nameplate horsepower less than 1 hp (746 W) are exempt from this section.

Reason: 1. This proposal corrects an IP / SI conversion error related to shaft power: 6 bhp equals 4476 W mechanical power.
2. It proposes moving the clause about *fan system motor nameplate* into the exceptions section for better clarity.

3. This proposal increases the design options for load-matching variable-speed fan motors, accommodates new motor and drive technologies, and it simplifies the motor selection criteria for fans.

Only motors that are government regulated in terms of test procedure and labeling have verifiable output power rating on the nameplates. None-covered motor types that are common for fans are air-over rated motors and electronically commutated permanent magnet motors. All other advanced motor topologies also prevent straight-forward motor output power ratings.

Even the nameplate output power rating of government regulated motors is irrelevant when the fan design duty...
requires variable frequency drive operation below 60 Hz. Then the motor horsepower must be oversized to deliver the required torque.

AC induction motors operated with variable frequency drives maintain high efficiency at part load. Permanent magnet fan motors maintain even higher efficiency. For all so-called power drive applications exists a self-regulating effect because of the higher marginal cost of oversized combinations of drives and motors as opposed to oversized induction motors for across-the-line operation. The existing restriction of motor selections provides no benefits in the case of fans with electronic variable-speed controls.

Small fans especially are often supplied strictly with electrical input power ratings rather than motor output power ratings. A lower limit expressed in electrical input power is therefore needed. The original 1 hp motor nameplate output power limit equates to 0.89 kW electrical motor input power according to the reference motor in ANSI/AMCA 208.

**Bibliography:**
- ANSI/AMCA 208 Calculation of the Fan Energy Index
  Courtesy copy available for the IECC committee through AMCA.
- The term “power drive system” is established in IEC 61800 and in ANSI/ASHRAE standard 222.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. It removes restrictions for fan selections with electronic power drive systems such as variable frequency drives and electronically committed motors.
FAN, EMBEDDED. A fan that is part of a manufactured assembly where the assembly includes functions other than air movement.

FAN ARRAY. Multiple fans in parallel between two plenum sections in an air distribution system.

FAN ENERGY INDEX (FEI) The ratio of the electric input power of a reference fan to the electric input power of the actual fan as calculated in accordance with AMCA 208.

FAN NAMEPLATE ELECTRICAL INPUT POWER The nominal electrical input power rating stamped on a fan assembly nameplate.

FAN SYSTEM ELECTRICAL INPUT POWER. The sum of the fan electrical power of all fans that are required to operate at fan system design conditions to supply air from the heating or cooling source to the conditioned spaces and/or return it to the source or exhaust it to the outdoors.

Delete and substitute as follows:

C403.8.3 Fan efficiency (Mandatory). Fans shall have a fan efficiency grade (FEG) of not less than 67, as determined in accordance with AMCA 205 by an approved, independent testing laboratory and labeled by the manufacturer. The total efficiency of the fan at the design point of operation shall be within 15 percentage points of the maximum total efficiency of the fan.

Exception: The following fans are not required to have a fan efficiency grade:

1. Fans of 5 hp (3.7 kW) or less as follows:
   1.1. Individual fans with a motor nameplate horsepower of 5 hp (3.7 kW) or less, unless Exception 1.2 applies.
   1.2. Multiple fans in series or parallel that have a combined motor nameplate horsepower of 5 hp (3.7 kW) or less and are operated as the functional equivalent of a single-fan.

2. Fans that are part of equipment covered in Section C403.3.2.

3. Fans included in an equipment package certified by an approved agency for air or energy performance.

4. Powered wall/roof ventilators.

5. Fans outside the scope of AMCA-205.

6. Fans that are intended to operate only during emergency conditions.

C403.8.3 Fan efficiency (Mandatory). Each fan and fan array shall have a fan energy index (FEI) of not less than 1.00 at the design point of operation, as determined in accordance with AMCA 208 by an approved, independent testing laboratory and labeled by the manufacturer. Each fan and fan array used for a variable-air-volume system shall have an FEI of not less than 0.95 at the design point of operation as determined in
accordance with AMCA 208 by an approved, independent testing laboratory and labeled by the manufacturer. The FEI for fan arrays shall be calculated in accordance with Annex C of AMCA 208.

**Exceptions:** The following fans are not required to have a fan energy index:

1. Fans that are not embedded fans with motor nameplate horsepower of less than 1.0 hp (0.75 kW) or less with a fan nameplate electrical input power of less than 0.89 kW.

2. Embedded fans that have a motor nameplate horsepower of 5 hp (3 kW) or less or with a fan system electrical input power of 4.1 kW or less.

3. Multiple fans operated in series or parallel as the functional equivalent of a single fan that have a combined motor nameplate horsepower of 5 hp (3.7 kW) or less or with a fan system electrical input power of 4.1 kW or less.

4. Fans that are part of equipment covered in Section C403.3.2.

5. Fans included in an equipment package certified by an approved agency for air or energy performance.

6. Ceiling fans, i.e., non portable devices suspended from a ceiling or overhead structure for circulating air via the rotation of fan blades.

7. Fans used for moving gases at temperatures above 482°F (250°C)

8. Fans used for operation in explosive atmospheres.

9. Reversible fans used for tunnel ventilation.

10. Fans that are intended to operate only during emergency conditions.

11. Fans outside the scope of AMCA 208.

Add new standard(s) as follows:

**AMCA**

**208-18: Calculation of the Fan Energy Index**

**Reason:** This proposal updates the current fan efficiency metric from a Fan Efficiency Grade (FEG) to a more current and improved metric known as Fan Energy Index (FEI). It also updates terms in the definitions chapter. This proposal also updates the definitions and associated standards for this new metric.

In the course of a U.S. Department of Energy (DOE) rulemaking for commercial fans and blowers, a wire-to-air metric was deemed to be more effective at saving energy because it would consider the impacts of motors and drives on fan energy performance. Although DOE has since stalled the fan rulemaking, the State of California has initiated an efficiency regulation for commercial and industrial fans under its Title 20 appliance/equipment efficiency standard.

Stemming from a public negotiation of fan-industry stakeholders (manufacturers, efficiency advocates,
consulting engineers, and a DOE representative), the Fan Energy Index (FEI), was developed by AMCA International and member companies, working collaboratively with efficiency advocates and DOE. FEI is defined in the calculation standard, ANSI/AMCA 208-2018.

Energy savings will primarily result from better fan selections out of existing product portfolios rather than marginal improvements from costly fan redesigns. FEI incentivizes a good match of the fan with its mechanical drive and the electric motor even at part load. The fan velocity pressure is credited in the FEI metric for fans with ducted outlets. Velocity pressure is not included for fans with unducted outlets.

The lower scope limit is expressed in nameplate motor output power and in nameplate fan electrical input power because only the former is available for some fans and for others only the latter. The conversion from motor output power to fan input power uses the reference motor efficiency curve fit from AMCA 208.

FEI will be easier to enforce over FEG because language requiring that fans be selected “15-percentage points from peak total efficiency” is no longer needed. Also, FEI applies to all types of fans, so the exclusions for PRVs and panel fans go away, bringing a fan-efficiency requirement to more fans than previously covered.

**Bibliography:**

Title: New Federal Regulations for Ceiling Fans  
Authors: New Federal Regulations for Ceiling Fans  
Published: ASHRAE Journal, January 2018

File: 42-46_Taber-Ivanovich_Fans, for Web.pdf

Keywords: large diameter, ceiling fans, efficiency, performance, U.S. Department of Energy, DOE, AMCA Standard 230, AMCA Standard 208, fan energy index, FEI

Abstract: In January 2017, the U.S. Department of Energy (DOE) finalized its first efficiency performance standards for ceiling fans, which include minimum efficiency requirements for large-diameter ceiling fans. Ratings using the DOE test procedure allow comparisons of products based on electric input power and airflow. Because the DOE performance metric is not based on a specific airflow point, some additional effort on the part of the designer may be required to evaluate fan performance equitably at a specific airflow point. Here are four things to know about the DOE’s regulation of ceiling fans that will help to ensure a successful and efficient ceiling-fan selection.

**Cost Impact:** The code change proposal will increase the cost of construction
This proposal could, in some cases increase the cost of construction. However, these potential increases are cost effective. Moreover, this proposal will result in better fan selections out of existing product portfolios rather than marginal improvements from costly fan redesigns.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, AMCA 208-18, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Energy Conservation Code

Delete without substitution:

C403.8.3 Fan efficiency (Mandatory). Fans shall have a fan efficiency grade (FEG) of not less than 67, as determined in accordance with AMCA 205 by an approved, independent testing laboratory and labeled by the manufacturer. The total efficiency of the fan at the design point of operation shall be within 15 percentage points of the maximum total efficiency of the fan.

Exception: The following fans are not required to have a fan efficiency grade:

1. Fans of 5 hp (3.7 kW) or less as follows:
   1.1. Individual fans with a motor nameplate horsepower of 5 hp (3.7 kW) or less, unless Exception 1.2 applies.
   1.2. Multiple fans in series or parallel that have a combined motor nameplate horsepower of 5 hp (3.7 kW) or less and are operated as the functional equivalent of a single fan.
2. Fans that are part of equipment covered in Section C403.3.2.
3. Fans included in an equipment package certified by an approved agency for air or energy performance.
4. Powered wall/roof ventilators.
5. Fans outside the scope of AMCA 205.
6. Fans that are intended to operate only during emergency conditions.

Reason: AMCA International and a consensus of its member companies worked through the US DOE and ASHRAE to develop an improved metric for inclusion into the codes. For this reason, this proposal deletes the antiquated metric: Fan Efficiency Grade from this section.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This will eliminate an outdated requirement, which could decrease the cost of the fan selected for a given application.
Add new definition as follows:

**FAN, EMBEDDED.** A fan that is part of a manufactured assembly where the assembly includes functions other than air movement.

**FAN ARRAY.** Multiple fans in parallel between two plenum sections in an air distribution system.

**FAN NAMEPLATE ELECTRICAL INPUT POWER.** The nominal electrical input power rating stamped on a fan assembly nameplate.

**FAN ENERGY INDEX (FEI).** The ratio of the electric input power of a reference fan to the electric input power of the actual fan as calculated in accordance with AMCA 208.

**FAN SYSTEM ELECTRICAL INPUT POWER.** The sum of the fan electrical power of all fans that are required to operate at fan system design conditions to supply air from the heating or cooling source to the conditioned spaces and/or return it to the source or exhaust it to the outdoors.

Revise as follows:

**C403.8.3 Fan efficiency (Mandatory).** Each fan and fan array shall have a fan efficiency grade energy index (FEG, FEI) of not less than 67 1.00 at the design point of operation, as determined in accordance with AMCA 205 208 by an approved, independent testing laboratory and labeled by the manufacturer. The total efficiency of the fan and fan array used for a variable-air-volume system shall have an FEI of not less than 0.95 at the design point of operation shall be within 15 percentage points of the maximum total efficiency of the fan, as determined in accordance with AMCA 208 by an approved, independent testing laboratory and labeled by the manufacturer. The FEI for fan arrays shall be calculated in accordance with AMCA 208 Annex C.

**Exceptions:** The following fans are not required to have a fan efficiency grade energy index:

1. Fans that are not embedded fans with motor nameplate horsepower of less than 1.0 hp (0.75 kW) or with a nameplate electrical input power of less than 0.89 kW.

2. Embedded fans that have a motor nameplate horsepower of 5 hp (3.7 kW) or less as follows: 1.1. Individual fans or with a fan system electrical input power of 4.1 kW or less.

3. Multiple fans operated in series or parallel as the functional equivalent of a single fan that have a combined motor nameplate horsepower of 5 hp (3.7 kW) or less and are operated as the functional equivalent of a single fan, or with a fan system electrical input power of 4.1 kW or less.

4. Fans that are part of equipment covered in Section C403.3.2.

5. Fans included in an equipment package certified by an approved agency for air or energy performance.
4. Powered wall/roof ventilators.
5. Fans outside the scope of AMCA 205.
6. Ceiling fans, i.e., nonportable devices suspended from a ceiling or overhead structure for circulating air via the rotation of the blades.
7. Fans used for moving gases at temperatures above 425°F (250 °C).
8. Fans used for operation in explosive atmospheres.
9. Reversible fans used for tunnel ventilation.
10. Fans that are intended to operate only during emergency conditions.
11. Fans outside the scope of AMC208.

Arlington Heights IL 60004-1806

208-18: Calculation of the Fan Energy Index

Reason: This proposal harmonizes the recent revisions in Addendum ao of ASHRAE 90.1, which will be in the 2019 edition of the standard. Replacing the Fan Efficiency Grade (FEG) metric with Fan Energy Index (FEI) will result in a more effective energy savings metric and updates the corresponding definitions and standard. FEI was developed in response to the U.S. Department of Energy (DOE) rulemaking for commercial fans and blowers, whereby a wire-to-air metric was deemed to be more effective at saving energy because it would consider the impacts of motors and drives on fan energy performance. Although DOE has since stalled the fan rulemaking, the State of California has initiated an efficiency regulation for commercial and industrial fans under its Title 20 appliance/equipment efficiency standard. FEI has been added to the DOE EnergyPlus software and to the DOE Fan System Assessment Tool. Unlike FEG, FEI can be used in calculations for energy savings, and it does not require a “sizing/selection window,” which makes enforcement easier.

a. When tested in accordance with HVI Standard 916. Fan efficacy for HRV, ERV, balanced, and in-line fans shall be taken at a static pressure >= 0.2 in. w.c. Fan efficacy for range hoods, bathroom, and utility room fans shall be taken at a static pressure >= 0.1 in. w.c.

**Reason:** Exhaust fan efficacies were introduced in the code in 2012 IECC for whole-house ventilation in low-rise residential buildings, but have never been included in the commercial provisions of the IECC. Mid-rise residential occupancies and small commercial buildings often utilize the same small ventilation fans leaving a loophole for a common energy load. These fans are used for point-of-source contaminant exhaust and are frequently utilized as part of a ventilation strategy in multifamily buildings. These fans are also smaller than the threshold for fan size (1/12 HP) that is attached to the other commercial fan requirements. This makes them a common load, and a potentially significant load in multifamily buildings, that is completely unregulated in commercial buildings.

This proposal adopts the table approach already utilized for these fans in the residential section of the code. However, it updates the efficiency requirements. The current residential IECC fan efficacies are from an older version of Energy Star (Version 2.0), so these have been updated to align the latest Energy Star requirement Version 4.0. These fan efficacy values are very conservative based on what is currently on the market.

It sets the efficiency requirement at a level that can reasonably be met by a large number of products available on the market. According to the HVI database of fans, the average efficiency of bath fans is around 7 CFM/W, and the average efficiency of in-line fans is 3.1. This proposal, therefore, places the requirement far below the
market average efficiency for bath fans and close to the market average for in-line fans, making this a reasonable requirement.

Another proposal has been submitted to the residential section of the code to update those fan efficacy requirements to the same levels.

**Cost Impact:** The code change proposal will increase the cost of construction. The proposal could increase the cost of construction. Cost for the kinds of fans covered by this requirement are not driven solely by efficacy. Cost is also a function of flow rate, finishes, design and noise and whether they include other features like lights, sensors, or heaters. In some cases, fans that meet this requirement can be obtained for less other fans that do not. Nevertheless, a comparison of the low-cost exhaust fans shows that this proposal can result in no incremental first costs or short simple paybacks where incremental costs are incurred.

For example, no-frills bath fans from major manufacturers moving a minimum of 50 to ~100 cfm at 0.25" w.c. have an immediate payback (i.e., no cost premium) or a simple payback estimated at ≤6 years where there is a cost premium (see Tables 1 and 2). The 2021 IRC requires exhaust fans to be rated at a static pressure of 0.25" w.c., which is widely recognized as a typical installed static pressure found in bath fan exhaust ducts.

*Simple payback assumes $0.1178/kWh (DOE EIA national average for residential and commercial), 1-hour of operation per day. Pricing sourced from homedepot.com on 1/9/2019. For Delta, the lowest price fan having at flow rate $\geq$ 50 cfm and $< 90$ cfm at 0.25" w.c. also had a fan efficacy meeting the proposed value, so there is no price premium associated with the manufacturer’s lowest cost product, and payback is “immediate”.

Panasonic FV-08-11VFS (entry-level at 0.25" w.c. is compliant with proposal) | 4.2 | 104 | -- | immediate

*Simple payback assumes $0.1178/kWh (DOE EIA national average for residential and commercial), 4-hours of operation per day (higher run time associated with assumption that higher flow rate bath fans are more likely to be installed in commercial bathrooms which are more likely to run continuously or at longer run times than a typical 1-hour residential assumption). Pricing sourced from homedepot.com on 1/9/2019. For some manufacturers, such as Delta and Panasonic, the lowest price fan having at flow rate ≥ 50 cfm and < 90 cfm at 0.25" w.c. also had a fan efficacy meeting the proposed value, so there is no price premium associated with the manufacturer’s lowest cost product, and payback is “immediate”.

Proposal # 5038

CE140-19
LARGE-DIAMETER CEILING FAN. A ceiling fan that is greater than 7 feet (2134 mm) in diameter. These fans are sometimes referred to as High-Volume, Low-Speed (HVLS) fans.

C403.9 Large-diameter ceiling fans. Where provided, large diameter ceiling fans shall be tested and labeled in accordance with AMCA 230.

ANSI/AMCA 230-15: Laboratory Methods of Testing Air Circulating Fans for Rating and Certification

Reason: This proposal brings in the definition for large diameter ceiling fans (LDCF) that is consistent with the DOE fan regulations and also the International Mechanical Code. Additionally, this proposal includes language and reference for the appropriate testing standard for these fans when they are installed. The addition of this language will be beneficial to the countries and states that adopt the IECC and not the IMC. This section and standard is also needed because language for giving credit for these fans in the performance path was approved into the 2018 IECC last cycle.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is not requiring anything new, as the IMC already requires these fans to comply with this standard.

Staff Analysis: A review of the standard proposed for inclusion in the code, AMCA 230-15, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Energy Conservation Code

Revise as follows:

**C403.9.4 Tower flow turndown.** Open-circuit cooling towers used on water-cooled chiller systems that are configured with multiple- or variable-speed condenser water pumps shall be designed so that all open-circuit cooling tower cells can be run in parallel with the larger of the flow that is produced by the smallest pump at its minimum expected flow rate or at 50 percent of the design flow for the cell.

*Exception:* Cooling towers used during wintertime heat rejection conditions where reducing water flow could cause freezing problems.

*Reason:* There isn’t any need to design a system to operate in a manner under which it can never be operated because of the concern for system damage. Correct system design for an application doesn’t result in additional materials or installation labor over that required for an incorrectly designed system that has to be immediately re-worked in the field. In the long run, this proposal will also save money from having to replace parts of the system that are damaged or ruined when the flow becomes so little that the system freezes up and is damaged.

*Cost Impact:* The code change proposal will not increase or decrease the cost of construction. This change will save money from having to replace parts of the system that are damaged or ruined if the flow is so little it freezes up and damages the system.
2018 International Energy Conservation Code

Add new text as follows:

C403.9.6 Heat recovery for space conditioning in healthcare facilities Where heating water is used for space heating, a condenser heat recovery system shall be installed provided all of the following are true:

1. The building is a Group I-2 Condition 2 occupancy
2. The total design chilled water capacity for the Group I-2 Condition 2 occupancy, either air cooled or water cooled, required at cooling design conditions exceeds 3,600,000 Btu/h (1,100 kW) of cooling.
3. Simultaneous heating and cooling occurs above 60°F (16°C) outdoor air temperature.

The required heat recovery system shall have a cooling capacity that is not less than 7 percent of the total design chilled water capacity of the Group I-2 Condition 2 occupancy at peak design conditions.

Exceptions:

1. Buildings that provide 60 percent or more of their reheat energy from on-site renewable energy or site-recovered energy.
2. Buildings in Climate Zones 5C, 6B, 7 and 8.

Reason: Most I-2 Condition 2 occupancies use reheat HVAC systems with simultaneous heating and cooling. Even with required air or water economizers, there are many hours with simultaneous heating and cooling use. It is generally lower cost to generate heating water with a heat recovery chiller or heat pump when the chilled water generated is useful than it is to use a boiler that complies with 90.1. Evaluation of a typical hospital in multiple climate zones shows a potential for reasonable recovery with a heat recovery chiller or heat pump that is sized between 7% and 12% of the cooling plant, depending on climate zone. For simplification and conservative, the minimum is set at 7% of total cooling load across the board.

An economic analysis was made using the 90.1 scalar method based on installed heat recovery chiller costs of $1,800 per ton. The resulting paybacks were all under 10 years for required climate zones vs. a scalar limit of 13 years. The trend of higher savings in warmer climate zones was used to include climate zones 1 and 0 without specific analysis. The payback in Climate Zone 2B was under 5 years.

Bibliography: Addendum V to 90.1-2016

Cost Impact: The code change proposal will increase the cost of construction. The code change proposal will increase the cost of construction due to equipment and infrastructure costs. The payback for such installations is less than 10 years in all required climate zones.

Proposal # 4895
2018 International Energy Conservation Code

Revise as follows:

**C402.1 General (Prescriptive).** Building thermal envelope assemblies for buildings that are intended to comply with the code on a prescriptive basis in accordance with the compliance path described in Item 2 of Section C401.2, shall comply with the following:

1. The opaque portions of the building thermal envelope shall comply with the specific insulation requirements of Section C402.2 and the thermal requirements of either the R-value-based method of Section C402.1.3; the U-, C- and F-factor-based method of Section C402.1.4; or the component performance alternative of Section C402.1.5.
2. Roof solar reflectance and thermal emittance shall comply with Section C402.3.
3. Fenestration in building envelope assemblies shall comply with Section C402.4.
4. Air leakage of building envelope assemblies shall comply with Section C402.5.

Alternatively, where buildings have a vertical fenestration area or skylight area exceeding that allowed in Section C402.4, the building and building thermal envelope shall comply with Section C401.2, Item 1 or Section C401.2, Item 3.

Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with Section C403.10.1 or C403.10.2.

**C403.10 Refrigeration equipment performance.** Refrigeration equipment shall have an energy use in kWh/day not greater than the values of Tables C403.10.1(1) and C403.10.1(2) when tested and rated in accordance with AHRI Standard 1200. The energy use shall be verified through certification under an approved certification program or, where a certification program does not exist, the energy use shall be supported by data furnished by the equipment manufacturer.

*Exception:* Walk-in coolers and walk-in freezers regulated under federal law in accordance with Subpart R of 10 CFR 431.

**Reason:**
- This change will make enforcement easier for code officials by making explicit that they do not have to address the attributes of walk-in systems preempted by federal requirements.
- The IECC already references 10 CFR for furnaces, boilers, industrial equipment, electric motors, etc., all in similar scenarios (see: Table C403.3.2(5), C403.8.4, Table C404.2, C405.6, etc.).
- No changes to efficiency or definitions have been proposed.
- The references to C403.10.1 and C403.10.2 in C402.1 have been collapsed to reference the relevant parent section, C403.10.
- By providing a reference to the CFR, the guidance of the prescriptive list remains for international users.

The federal standard being referenced is Department of Energy in 10 CFR 431, Subpart R - Walk-in Coolers and Walk-in Freezers - it can be reviewed at this link: [https://www.law.cornell.edu/cfr/text/10/part-431/subpart-R](https://www.law.cornell.edu/cfr/text/10/part-431/subpart-R)

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost impact, because no requirements have been changed; the equipment already is preempted. Potentially, costs could be reduced by avoiding enforcement conflicts.
CE145-19

IECC: C402.1, C403.10.1, C403.10.2, C403.10.2.1, TABLE C403.10.2.1(1), TABLE C403.10.2.1(2), TABLE C403.10.2.1(3), C403.10.4, C405.1

2018 International Energy Conservation Code

Revise as follows:

**C402.1 General (Prescriptive).** Building thermal envelope assemblies for buildings that are intended to comply with the code on a prescriptive basis in accordance with the compliance path described in Item 2 of Section C401.2, shall comply with the following:

1. The opaque portions of the building thermal envelope shall comply with the specific insulation requirements of Section C402.2 and the thermal requirements of either the R-value-based method of Section C402.1.3; the U-, C- and F-factor-based method of Section C402.1.4; or the component performance alternative of Section C402.1.5.

2. Roof solar reflectance and thermal emittance shall comply with Section C402.3.

3. Fenestration in building envelope assemblies shall comply with Section C402.4.

4. Air leakage of building envelope assemblies shall comply with Section C402.5.

Alternatively, where buildings have a vertical fenestration area or skylight area exceeding that allowed in Section C402.4, the building and building thermal envelope shall comply with Section C401.2, Item 1 or Section C401.2, Item 3.

Walk-in coolers, walk-in freezers, refrigerated Refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with Section C403.10.1 or C403.10.2.

**Delete without substitution:**

**C403.10.1 Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers (Mandatory).** Refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with this section. Walk-in coolers and walk-in freezers that are neither site assembled nor site constructed shall comply with the following:

1. Be equipped with automatic door closers that firmly close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.  

   **Exception:** Automatic closers are not required for doors more than 4.5 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall have strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when doors are open.

3. Walk-in coolers and refrigerated warehouse coolers shall contain wall, ceiling, and door insulation of not less than R-25 and walk-in freezers and refrigerated warehouse freezers shall contain wall, ceiling and door insulation of not less than R-32.

   **Exception:** Glazed portions of doors or structural members need not be insulated.

4. Walk-in freezers shall contain floor insulation of not less than R-28.

5. Transparent reach-in doors for walk-in freezers and windows in walk-in freezer doors shall be of triple-pane glass, either filled with inert gas or with heat reflective treated glass.
6. Windows and transparent reach-in doors for walk-in coolers shall be of double-pane or triple-pane, inert gas-filled, heat-reflective treated glass.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall use electronically commutated motors, brushless direct-current motors, or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) shall use electronically commutated motors, permanent split capacitor-type motors or 3-phase motors.

9. Where antisweat heaters without antisweat heater controls are provided, they shall have a total door rail, glass and frame heater power draw of not more than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers and 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.

10. Where antisweat heater controls are provided, they shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Lights in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall either use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, or shall use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, in conjunction with a device that turns off the lights within 15 minutes when the space is not occupied.

Revise as follows:

**C403.10.2 Walk-in coolers and walk-in refrigerated warehouse coolers, refrigerated warehouse freezers (Mandatory).** Site-assembled or site-constructed walk-in Refrigerated warehouse coolers and walk-in refrigerated warehouse freezers shall comply with the following:

1. Automatic door closers shall be provided that fully close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   
   **Exception:** Closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall be provided with strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when the doors are open.

3. Walls shall be provided with insulation having a thermal resistance-Refrigerated warehouse cooler wall, ceiling, and door insulation shall have an R-value of not less than R-25, ceilings shall be provided with insulation having a thermal resistance of not less than R-25 and doors of walk-in coolers and walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-25. Refrigerated warehouse freezer wall, ceiling, and door insulation shall have an R-value of not less than R-32.

   **Exception:** Insulation is not required for glazed portions of doors or at structural members associated with the walls, ceiling or door frame.

4. The floor of walk-in refrigerated warehouse freezers shall be provided with insulation having a thermal resistance of not less than R-28.

5. Transparent Refrigerated warehouse freezer transparent reach-in doors for walk-in freezers and windows in opaque walk-in freezer doors shall be provided with triple-pane glass having the interstitial spaces filled with inert gas or provided with heat-reflective treated glass.

6. Transparent Refrigerated warehouse cooler transparent reach-in doors for walk-in coolers and windows in opaque walk-in cooler doors shall be double-pane heat-reflective treated glass having the interstitial space gas filled.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall be electronically commutated motors, brushless direct-current motors, or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) in capacity shall be of the electronically commutated or permanent split capacitor-type or shall be 3-phase motors.

   **Exception:** Fan motors in walk-in refrigerated warehouse coolers and walk-in refrigerated warehouse freezers shall be of double-pane or triple-pane, inert gas-filled, heat-reflective treated glass.
whereas warehouse freezers combined in a single enclosure greater than 3,000 square feet (279 m²) in floor area are exempt.

9. Antisweat heaters that are not provided with Where antisweat heaters without anti-sweat heater controls are provided, they shall have a total door rail, glass , and frame heater power draw not greater than 7.1 W/ft² (76 W/m²) of door opening for walk-in refrigerated warehouse freezers, and not greater than 3.0 W/ft² (32 W/m²) of door opening for walk-in refrigerated warehouse coolers.

10. Antisweat Where antisweat heater controls are provided, they shall be configured to reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Light sources shall have an efficacy of not less than 40 lumens per Watt, including any ballast losses, or shall be provided with a device that automatically turns off the lights within 15 minutes of when the walk-in cooler or walk-in freezer was last occupied.

Delete without substitution:

C403.10.2.1 Performance standards (Mandatory). Effective January 1, 2020, walk-in coolers and walk-in freezers shall meet the requirements of Tables C403.10.2.1(1), C403.10.2.1(2) and C403.10.2.1(3).

| DEDICATED | 5.61 |
Revise as follows:

C403.10.4 Refrigeration systems. Refrigerated display cases, walk-in refrigerated warehouse coolers or walk-in refrigerated warehouse freezers that are served by remote compressors and remote condensers not located in a condensing unit, shall comply with Sections C403.10.4.1 and C403.10.4.2.

Exception: Systems where the working fluid in the refrigeration cycle goes through both subcritical and super-critical states (transcritical) or that use ammonia refrigerant are exempt.

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption.

Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2: C403.10.1.

Reason: The intent of this proposal is to avoid changing requirements, to the extent possible, while maintaining requirements for non-preempted equipment. This proposal coordinates with other proposals attempting to resolve preemption and testing uniformity issues. There are no non-preempted walk-in coolers and walk-in freezers in the IECC. Coolers and freezers under 3,000ft2 fall under 10 CFR Part 431, Subpart R (as defined by 431.302):

“Walk-in cooler and walk-in freezer mean an enclosed storage space refrigerated to temperatures, respectively, above, and at or below 32 degrees Fahrenheit that can be walked into, and has a total chilled storage area of less than 3,000 square feet; however the terms do not include products designed and marketed exclusively for medical, scientific, or research purposes.” (emphasis added)

The IECC definitions (see proposal) limit walk-in coolers and walk-in freezers to less than 3,000ft2, matching the scope of the preemption. Having two sets of requirements - the CFR and the IECC - causes problems, both for building officials and product manufacturers. Having failed in the last cycle to provide an exception for equipment within the scope of the CFR, this proposal removes preempted equipment by removing all "walk-ins," since they are - by definition - preempted. Non-preempted "walk-in" coolers and freezers are defined in the IECC as refrigerated warehouse coolers and refrigerated warehouse freezers, being 3,000ft2 or larger.

Because there still is legal uncertainty regarding the future of the federal preemption requirements, the prescriptive list in (renumbered) C403.10.1 is retained, if only for non-preempted (3,000ft2+) "walk-in" systems. Other proposals update and incorporate newly-effective federal requirements. Where defined walk-in coolers and freezers have requirements in other sections, the defined term has been replaced with refrigerated warehouse coolers and freezers, as applicable, to provide requirements for non-preempted equipment. The conditions currently regulated for walk-in coolers and walk-in freezers might not exist in all refrigerated warehouse coolers and refrigerated warehouse freezers, and would not be applicable in those cases. Additionally, a redundancy between C403.10.1 and C403.10.2 is being addressed by deleting X.1, and attempting to incorporate some clarity improvements to X.2 proposed by SEHPCAC (CE124-16) during the last development cycle.
The desire for language for non-U.S. jurisdictions, where <3,000ft² walk-ins are not preempted, is appreciated, but here causes conflict domestically for the overwhelming majority of code users, officials, and manufacturers.

**Bibliography:** 10 CFR Part 431, Subpart R - Walk-in Coolers and Walk-in Freezers.
10 CFR 431.302 - Definitions concerning walk-in coolers and walk-in freezers.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
The intent of this proposal is to align the code with the current regulatory hierarchy. Equipment already should meet these requirements, so cost should be unaffected or reduced, due to fewer enforcement conflicts.

IECC: C403.10, C403.10.1, TABLE C403.10.1(1), TABLE C403.10.1(2), C403.10.3, Chapter 6CE (New)

Proponent: Amanda Hickman, representing AHRI (amanda@thehickmangroup.com)

2018 International Energy Conservation Code

Revise as follows:

C403.10 Refrigeration equipment performance. Refrigeration equipment shall have an energy use in kWh/day not greater than the values of Tables C403.10.1(1) and C403.10.1(2) when tested and rated in accordance with AHRI Standard 1200. Performance shall be determined in accordance with sections C403.10.1 and C403.10.2 for commercial refrigerators, freezers, refrigerator-freezers, walk-in coolers, walk-in freezers and refrigeration equipment. The energy use shall be verified through certification under an approved certification program or, where a certification program does not exist, the energy use shall be supported by data furnished by the equipment manufacturer.

C403.10.1 Walk-in coolers Commercial refrigerators, walk-in freezers, refrigerated-warehouse coolers and refrigerated-warehouse freezers refrigerator-freezers and refrigeration (Mandatory). Refrigeration equipment, defined in U.S. 10 CFR part 431.62, shall have an energy use in kWh/day not greater than the values of Table C403.10.1(1) when tested and rated in accordance with AHRI Standard 1200. Refrigerated warehouse coolers and refrigerated-warehouse freezers shall comply with this section. Walk-in coolers and walk-in freezers that are neither site-assembled nor site-constructed shall comply with the following:

1. Be equipped with automatic door closers that firmly close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   
   **Exception:** Automatic closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall have strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when doors are open.

3. Walk-in coolers and refrigerated-warehouse coolers shall contain wall, ceiling, and door insulation of not less than R-25 and walk-in freezers and refrigerated-warehouse freezers shall contain wall, ceiling and door insulation of not less than R-32.
   
   **Exception:** Glazed portions of doors or structural members need not be insulated.

4. Walk-in freezers shall contain floor insulation of not less than R-28.

5. Transparent reach-in doors for walk-in freezers and windows in walk-in freezer doors shall be of triple-pane glass, either filled with inert gas or with heat-reflective treated glass.

6. Windows and transparent reach-in doors for walk-in coolers shall be of double-pane or triple-pane, inert-gas-filled, heat-reflective treated glass.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall use electronically-commutated motors, brushless direct-current motors, or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) shall use electronically-commutated motors, permanent split capacitor-type motors or 3-phase motors.

9. Where antisweat heaters without antisweat heater controls are provided, they shall have a total door rail, glass and frame heater power draw of not more than 7.1 W/ft² (76 W/m²) of door.
opening for walk-in freezers and 3.0 W/ft$^2$ (32 W/m$^2$) of door opening for walk-in coolers.

10. Where antisweat heater controls are provided, they shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Lights in walk-in coolers, walk-in freezers, refrigerated-warehouse coolers and refrigerated-warehouse freezers shall either use light sources with an efficacy of not less than 40 lumens-per-watt, including ballast losses, or shall use light sources with an efficacy of not less than 40 lumens-per-watt, including ballast losses, in conjunction with a device that turns off the lights within 15 minutes when the space is not occupied.

a. The meaning of the letters in this column is indicated in the columns to the left.

b. Ice-cream freezer is defined in 10 CFR 431.62 as a commercial freezer that is designed to operate at or below −5 °F and that the manufacturer designs, markets, or intends for the storing, displaying, or dispensing of ice cream.

c. Equipment class designations consist of a combination (in sequential order separated by periods (AAA).(BB). (C)) of the following:
   (AAA)—An equipment family code (VOP = vertical open, SVO = semivertical open, HZO = horizontal open, VCT = vertical closed transparent doors, VCS = vertical closed solid doors, HCT = horizontal closed transparent doors, HCS = horizontal closed solid doors, and SOC = service over counter); (BB)—An operating mode code (RC = remote condensing and SC = self-contained); and (C)—A rating temperature code (M = medium temperature [38 °F], L = low temperature [0 °F], or I = ice cream temperature [-15 °F]). For example, “VOP.RC.M” refers to the “vertical open, remote condensing, medium temperature” equipment class.

d. V is the volume of the case (ft³) as measured in AHRI Standard 1200, Appendix C.

e. TDA is the total display area of the case (ft²) as measured in AHRI Standard 1200, Appendix D.

ICC COMMITTEE ACTION HEARINGS :: April, 2019

CE399
C403.10.3 Refrigerated display cases (Mandatory). Site-assembled or site-constructed refrigerated display cases shall comply with the following:

1. Lighting and glass doors in refrigerated display cases shall be controlled by one of the following:
   1.1. Time-switch controls to turn off lights during nonbusiness hours. Timed overrides for display cases shall turn the lights on for up to 1 hour and shall automatically time out to turn the lights off.
   1.2. Motion sensor controls on each display case section that reduce lighting power by not less than 50 percent within 3 minutes after the area within the sensor range is vacated.

2. Low-temperature display cases shall incorporate temperature-based defrost termination control with a time-limit default. The defrost cycle shall terminate first on an upper temperature limit breach and second upon a time-limit breach.

3. Antisweat heater controls shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

Add new text as follows:

**DOE**

U.S. Department of Energy
c/o Superintendent of Documents
1000 Independence Avenue SW
Washington DC 20585

**U.S. 10 Part CFR 431, Subpart R: Commercial Refrigerators, Freezers and Refrigerator-Freezers**

**AHRI**

Air-Conditioning, Heating, & Refrigeration Institute
2111 Wilson Blvd, Suite 500
Arlington VA 22201

**AHRI 1250-(I-P) 2014:**

**Standard for Performance Rating in Walk-in Coolers and Freezers**

**Reason:** This proposal removes the conflict with current federal regulations and updates this section by replacing the outdated prescriptive language to be consistent with current DOE regulations. It also combines the current tables into one, which harmonizes with the federal regulations and recent updates made to ASHRAE 90.1.

**Bibliography:** 1. ENERGY INDEPENDENCE AND SECURITY ACT OF 2007, Section 312, Walk-in Coolers and
Walk-in Freezers.

3. 2014-06-03 Energy Conservation Program: Energy Conservation Standards for Walk-In Coolers and Freezers; Final Rule

https://www.ecfr.gov/cgi-bin/retrieveECFR?gp=&SID=396fdbc135febfc51995dca67c2cee17&mc=true&n=pt10.3.431&r=P ART&ty=HTML#sp10.3.431.c

**Cost Impact:** The code change proposal will decrease the cost of construction
This proposal updates the requirements to the current federal mandate, clarifying that there are no additional requirements that need to be satisfied. Deleting the additional requirements will drastically reduce the cost to the consumer, and thereby reducing the cost of construction.

Proposal # 5379

CE146-19
Proponent: Thomas D. Culp, Ph.D., Birch Point Consulting LLC, representing self (culp@birchpointconsulting.com)

2018 International Energy Conservation Code

Revise as follows:

C402.1 General (Prescriptive). Building thermal envelope assemblies for buildings that are intended to comply with the code on a prescriptive basis in accordance with the compliance path described in Item 2 of Section C401.2, shall comply with the following:

1. The opaque portions of the building thermal envelope shall comply with the specific insulation requirements of Section C402.2 and the thermal requirements of either the R-value-based method of Section C402.1.3; the U-, C- and F-factor-based method of Section C402.1.4; or the component performance alternative of Section C402.1.5.
2. Roof solar reflectance and thermal emittance shall comply with Section C402.3.
3. Fenestration in building envelope assemblies shall comply with Section C402.4.
4. Air leakage of building envelope assemblies shall comply with Section C402.5.

Alternatively, where buildings have a vertical fenestration area or skylight area exceeding that allowed in Section C402.4, the building and building thermal envelope shall comply with Section C401.2, Item 1 or Section C401.2, Item 3.

Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with Section C403.10.1 or C403.10.2.

C403.10.1 Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers (Mandatory). Refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with this section. Walk-in coolers and walk-in freezers that are neither site assembled nor site constructed shall comply with the following:

1. Be equipped with automatic door closers that firmly close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.

   Exception: Automatic closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall have strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when doors are open.

3. Walk-in coolers and refrigerated warehouse coolers shall contain wall, ceiling, and door insulation of not less than R-25 and walk-in freezers and refrigerated warehouse freezers shall contain wall, ceiling and door insulation of not less than R-32.

   Exception: Glazed portions of doors or structural members need not be insulated.

4. Walk-in freezers shall contain floor insulation of not less than R-28.

5. Transparent reach-in doors for walk-in freezers and windows in walk-in freezer doors shall be of triple-pane glass, either filled with inert gas or with heat-reflective treated glass.

6. Windows and transparent reach-in doors for walk-in coolers shall be of double-pane or triple-
7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall use electronically commutated motors, brushless direct-current motors, or 3-phase motors.
8. Condenser fan motors that are less than 1 hp (0.746 kW) shall use electronically commutated motors, permanent split capacitor-type motors or 3-phase motors.
9. Where antisweat heaters without antisweat heater controls are provided, they shall have a total door rail, glass and frame heater power draw of not more than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers and 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.
10. Where antisweat heater controls are provided, they shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.
11. Lights in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall either use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, or shall use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, in conjunction with a device that turns off the lights within 15 minutes when the space is not occupied.

C403.10.2 Walk-in coolers and walk-in freezers (Mandatory). Site-assembled or site-constructed Refrigerated warehouse coolers, refrigerated warehouse freezers, walk-in coolers, and walk-in freezers shall comply with the following:

1. Automatic door closers shall be provided that fully close walk-in doors that have been closed to within 1 inch (25 mm) of full closure. Exception: Closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.
2. Doorways shall be provided with strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when the doors are open.
3. Walls shall be provided with insulation having a thermal resistance of not less than R-25, ceilings shall be provided with insulation having a thermal resistance of not less than R-25 and doors of walk-in coolers and walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-32. Exception: Insulation is not required for glazed portions of doors or at structural members associated with the walls, ceiling or door frame.
4. The floor of walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-28.
5. Transparent reach-in doors for and windows in opaque walk-in freezer doors shall be provided with triple-pane glass having the interstitial spaces filled with inert gas or provided with heat-reflective treated glass, glass, or vacuum insulating glazing.
6. Transparent reach-in doors for and windows in opaque walk-in cooler doors shall be double-pane heat-reflective treated glass having the interstitial space gas filled, filled, or vacuum insulating glazing.
7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall be electronically commutated motors or 3-phase motors.
8. Condenser fan motors that are less than 1 hp (0.746 kW) in capacity shall be of the electronically commutated or permanent split capacitor-type or shall be 3-phase motors. Exception: Fan motors in walk-in coolers and walk-in freezers combined in a single enclosure greater than 3,000 square feet (279 m²) in floor area are exempt.
9. Antisweat heaters that are not provided with anti-sweat heater controls shall have a total door rail, glass and frame heater power draw not greater than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers, and not greater than 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.
10. Antisweat heater controls shall be configured to reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Light sources shall have an efficacy of not less than 40 lumens per Watt, including any ballast losses, or shall be provided with a device that automatically turns off the lights within 15 minutes of when the walk-in cooler or walk-in freezer was last occupied.

C403.10.2.1 Performance standards (Mandatory). Effective January 1, 2020,
Doors in walk-in coolers and walk-in freezers shall meet the requirements of Tables C403.10.2.1, C403.10.1(1), C403.10.2.1 and C403.10.1(2) and C403.10.2.1.

Walk-in cooler and walk-in freezer refrigeration systems, except for walk-in process cooling refrigeration systems as defined in U.S. 10 CFR 431.302, shall meet the requirements of Table C403.10.1(3).

\[ 4.15 \]

\[ a. \text{ q}_{\text{net}} \text{ is net capacity as determined in accordance with 10 CFR 431.304 and certified in accordance with 10 CFR part 429.} \]

**Reason:** The purpose of this proposal is to clean up outdated language regarding walk-in cooler and walk-in freezer requirements, and make the requirements consistent with current federal regulations that either already came into effect June 5, 2017 or will come into effect July 10, 2020 prior to implementation of the 2021 IECC. Most importantly, the performance requirements for walk-in coolers and freezer in Tables C403.10.2.1(1) through (3) are updated to be consistent with 10 CFR 431.306. Additionally, the redundant itemized lists in Sections C403.10.1 and C403.10.2 are combined into one section. There is no reason to repeat the same requirements twice that apply to both site-built and prefabricated walk-in coolers and freezers (defined as < 3,000 ft²) and refrigerated warehouse coolers and freezers (>3,000 ft²). Finally, vacuum insulating glazing is added to the list of allowed glazing options in reach-in doors, as the current wording could inadvertently be misinterpreted as not including vacuum insulating glazing. The thermal resistance of vacuum insulating glazing is at least twice that of other options (e.g. R10 for vacuum insulating glazing vs. R3-5 for the other options), so this ensures there is no unintended barrier to using these higher performance products.

Links to the federal standards are as follows:

10 CFR 431.302 - Definitions concerning walk-in coolers and walk-in freezers. [https://www.law.cornell.edu/cfr/text/10/431.302](https://www.law.cornell.edu/cfr/text/10/431.302)

10 CFR 431.304 - Uniform test method for the measurement of energy consumption of walk-in coolers and walk-in freezers. [https://www.law.cornell.edu/cfr/text/10/431.304](https://www.law.cornell.edu/cfr/text/10/431.304)

10 CFR Part 429 - Certification, compliance, and enforcement for consumer products and commercial and industrial equipment. [https://www.law.cornell.edu/cfr/text/10/part-429](https://www.law.cornell.edu/cfr/text/10/part-429)

**Cost Impact:** The code change proposal will increase the cost of construction

Increased product costs associated with the increased performance requirements were evaluated as part of the federal rulemaking process and deemed cost effective. For instance, see
2018 International Energy Conservation Code

Revise as follows:

C403.10.1 Walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers (Mandatory). Refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with this section. Walk-in coolers and walk-in freezers that are neither site assembled nor site constructed shall comply with the following:

1. Be equipped with automatic door-closers that firmly close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   **Exception:** Automatic closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall have strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when doors are open.

3. Walk-in coolers and refrigerated warehouse coolers shall contain wall, ceiling, and door insulation of not less than R-25 and walk-in freezers and refrigerated warehouse freezers shall contain wall, ceiling and door insulation of not less than R-32.
   **Exception:** Glazed portions of doors or structural members need not be insulated.

4. Walk-in freezers shall contain floor insulation of not less than R-28.

5. Transparent reach-in doors for walk-in freezers and windows in walk-in freezer doors shall be of triple-pane glass, either filled with inert gas or with heat-reflective treated glass, or vacuum insulating glazing.

6. Windows and transparent reach-in doors for walk-in coolers shall be of double-pane or triple-pane, inert gas-filled, heat-reflective treated glass, or vacuum insulating glazing.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall use electronically commutated motors, brushless direct-current motors, or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) shall use electronically commutated motors, permanent split capacitor-type motors or 3-phase motors.

9. Where antisweat heaters without antisweat heater controls are provided, they shall have a total door rail, glass and frame heater power draw of not more than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers and 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.

10. Where antisweat heater controls are provided, they shall reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Lights in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall either use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, or shall use light sources with an efficacy of not less than 40 lumens per watt, including ballast losses, in conjunction with a device that turns off the lights within 15 minutes when the space is not occupied.

C403.10.2 Walk-in coolers and walk-in freezers (Mandatory). Site-assembled or site-constructed walk-in coolers and walk-in freezers shall comply with the following:
1. Automatic door closers shall be provided that fully close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.  
   **Exception:** Closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall be provided with strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when the doors are open.

3. Walls shall be provided with insulation having a thermal resistance of not less than R-25, ceilings shall be provided with insulation having a thermal resistance of not less than R-25 and doors of walk-in coolers and walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-32.  
   **Exception:** Insulation is not required for glazed portions of doors or at structural members associated with the walls, ceiling or door frame.

4. The floor of walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-28.

5. Transparent reach-in doors for and windows in opaque walk-in freezer doors shall be provided with triple-pane glass having the interstitial spaces filled with inert gas or provided with heat-reflective treated glass, or vacuum insulating glazing.

6. Transparent reach-in doors for and windows in opaque walk-in cooler doors shall be double-pane heat-reflective treated glass having the interstitial space gas filled, or vacuum insulating glazing.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall be electronically commutated motors or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) in capacity shall be of the electronically commutated or permanent split capacitor-type or shall be 3-phase motors.  
   **Exception:** Fan motors in walk-in coolers and walk-in freezers combined in a single enclosure greater than 3,000 square feet (279 m²) in floor area are exempt.

9. Antisweat heaters that are not provided with anti-sweat heater controls shall have a total door rail, glass and frame heater power draw not greater than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers, and not greater than 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.

10. Antisweat heater controls shall be configured to reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Light sources shall have an efficacy of not less than 40 lumens per Watt, including any ballast losses, or shall be provided with a device that automatically turns off the lights within 15 minutes of when the walk-in cooler or walk-in freezer was last occupied.

**Reason:** The purpose of this proposal is to ensure the code does not prohibit the use of new vacuum insulating glazing products in reach-in doors for walk-in coolers and freezers. These high performance products have been recently commercialized by multiple manufacturers and are already being used in display doors for walk-in coolers, walk-in freezers, and stand-alone refrigerated display cases. However, items 5 and 6 of Sections C403.10.1 and C403.10.2 have specific limited options for reach-in doors: double pane glazing with argon and low-e glass for coolers, and triple pane glass with either argon or low-e glass for freezers. This is overly prescriptive and could be interpreted as not including vacuum insulating glazing, and introduces a barrier to these higher performance products. The thermal resistance of vacuum insulating glazing is at least twice that of other options (e.g. R10 for vacuum insulating glazing vs. R3-5 for the other options). Therefore, this proposal adds vacuum insulating glazing to the list of options for reach-in doors. These changes are necessary as it is important that an energy code not actually hinder the use of innovative, higher performance products.

Note: a separate proposal includes a comprehensive update to the entire walk-in cooler and freezer section, updating the performance requirement tables. However, this simple proposal at least addresses the specific
problem for vacuum insulating glazing, in case the code development body does not approve the broader proposal.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
While vacuum insulating glazing is more expensive than tradition glazing options for display doors, this is not a requirement to use vacuum insulating glazing. This proposal simply removes a barrier so that vacuum insulating glazing may be considered as an option.

Proposal # 4902

CE148-19
2018 International Energy Conservation Code

Revise as follows:

C403.10.2 Walk-in coolers and walk-in freezers (Mandatory). Walk-in cooler and walk-in freezer refrigeration systems, except for walk-in process cooling refrigeration systems as defined in U.S. 10 CFR 431.302, shall meet the requirements of Tables C403.10.2(1), C403.10.2(2), and C403.10.2(3). Site-assembled or site-constructed walk-in coolers and walk-in freezers shall comply with the following:

1. Automatic door closers shall be provided that fully close walk-in doors that have been closed to within 1 inch (25 mm) of full closure.
   Exception: Closers are not required for doors more than 45 inches (1143 mm) in width or more than 7 feet (2134 mm) in height.

2. Doorways shall be provided with strip doors, curtains, spring-hinged doors or other method of minimizing infiltration when the doors are open.

3. Walls shall be provided with insulation having a thermal resistance of not less than R-25, ceilings shall be provided with insulation having a thermal resistance of not less than R-25 and doors of walk-in coolers and walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-32.
   Exception: Insulation is not required for glazed portions of doors or at structural members associated with the walls, ceiling or door frame.

4. The floor of walk-in freezers shall be provided with insulation having a thermal resistance of not less than R-28.

5. Transparent reach-in doors for and windows in opaque walk-in freezer doors shall be provided with triple-pane glass having the interstitial spaces filled with inert gas or provided with heat-reflective treated glass.

6. Transparent reach-in doors for and windows in opaque walk-in cooler doors shall be double-pane heat-reflective treated glass having the interstitial space gas filled.

7. Evaporator fan motors that are less than 1 hp (0.746 kW) and less than 460 volts shall be electronically-commutated motors or 3-phase motors.

8. Condenser fan motors that are less than 1 hp (0.746 kW) in capacity shall be of the electronically commutated or permanent split capacitor type or shall be 3-phase motors.
   Exception: Fan motors in walk-in coolers and walk-in freezers combined in a single enclosure greater than 3,000 square feet (279 m²) in floor area are exempt.

9. Antisweat heaters that are not provided with anti-sweat heater controls shall have a total door rail, glass and frame heater power draw not greater than 7.1 W/ft² (76 W/m²) of door opening for walk-in freezers, and not greater than 3.0 W/ft² (32 W/m²) of door opening for walk-in coolers.
10. Antisweat heater controls shall be configured to reduce the energy use of the antisweat heater as a function of the relative humidity in the air outside the door or to the condensation on the inner glass pane.

11. Light sources shall have an efficacy of not less than 40 lumens per Watt, including any ballast losses, or shall be provided with a device that automatically turns off the lights within 15 minutes of when the walk-in cooler or walk-in freezer was last occupied.

| Dedicated condensing, low temperature, outdoor system, net capacity ($q_{net}$) $< 6,500$ Btu/h | DC.L.O. < 6,500 | $6.522 \times 10^{-5} \times q_{net} + 2.73$ |
| Dedicated condensing, low temperature, outdoor system, net capacity ($q_{net}$) $\geq 6,500$ Btu/h | DC.L.O. $\geq 6,500$ | 3.15 |
| Unit cooler, medium | UC.M | 9.00 |
| Unit cooler, low temperature, net capacity ($q_{net}$) $< 15,500$ Btu/h | UC.L. < 15,500 | $1.575 \times 10^{-5} \times q_{net} + 3.91$ |
| Unit cooler, low temperature, net capacity ($q_{net}$) $\geq 15,500$ Btu/h | UC.L. $\geq 15,500$ | 4.15 |

AHRI 1250-(I-P) 2014: Standard for Performance Rating in Walk-in Coolers and Freezers

**Reason:** This proposal is intended to update language regarding walk-in cooler and walk-in freezer requirements to be consistent with current federal regulations that are already in effect as well as with those that will become effective in 2020, prior to the publishing of this code. This will also harmonize the IECC with recent updates made to ASHRAE 90.1.

This proposal reorganizes and cleans up language by deleting the prescriptive requirements and updates the tables that are out of sync with U.S.10 CFR 431. This will streamline the requirements thereby reducing confusion for code officials.

**Bibliography:**
3. 2014-06-03 Energy Conservation Program: Energy Conservation Standards for Walk-In Coolers and Freezers; Final Rule

https://www.ecfr.gov/cgi-bin/retrieveECFR?gp=&SID=396fdbc135febfc51995dca67c2cee17&mc=true&n=pt10.3.431&r=P ART&ty=HTML#sp10.3.431.c

**Cost Impact:** The code change proposal will decrease the cost of construction

This proposal updates the requirements to the current federal mandate, clarifying that there are no additional requirements that need to be satisfied. Deleting the additional requirements will drastically reduce the cost to the consumer, and thereby reducing the cost of construction.
Staff Analysis: A review of the standard proposed for inclusion in the code, AHRI 1250-(I-P) 2014, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 5402

CE149-19
CE150-19 Part I

PART I — IECC: C403.11.3.1

PART II — IECC: R403.4.1 (IRC N1103.4.1)

Proponent: Howard Ahern, representing self (howard.ahern@airexmfg.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C403.11.3.1 Protection of piping insulation (Mandatory). Piping insulation exposed to the weather shall be protected from damage, including that caused by sunlight, moisture, wind, and physical damage. Protective barrier shall be removable for equipment maintenance and wind, and shall provide shielding from solar radiation that can cause degradation of the material. Adhesive tape shall not be permitted.

Proposal # 4565
Proponent: Howard Ahern, representing self (howard.ahern@airexmfg.com)

2018 International Energy Conservation Code

Revise as follows:

R403.4.1 (IRC N1103.4.1) Protection of piping insulation. Piping insulation exposed to weather shall be protected from damage, including that caused by sunlight, moisture, wind and physical damage. Protective barrier shall be removable for equipment maintenance and wind. The protection shall provide shielding from solar radiation that can cause degradation of the material. Adhesive tape shall be prohibited.

Reason: This proposal will clarify the intent of section R403.4.1. The intent of this section is not only protection of pipe insulation from weather but to insure the insulations thermal conductivity energy savings integrity last the life of the mechanical system as per the intent of the code. In order to remove the opportunity for misunderstanding so that the code has its’s intended result the term “equipment maintenance” must be clarified. The intent is in the original proponents reason statement of this requirement EC110-09/10 stated -“All AC units require periodic maintenance. The frequency varies with how hard the unit operates, exterior temperature, preventive maintenance program, and many others. In every occasion, every maintenance provides an excuse for the Freon line insulation to be touched and removed.” The intent is clear that the protection be removable and independent of the pipe insulation for maintenance without damaging the pipe insulation.

Removing protection without damaging the insulation is stated in EC110-09/10 “Adhesives Tape is not permitted as it will limit maintenance and damage insulations permeability characteristics. Removal of tape damages the integrity of the original insulation into pieces, specially, if the insulation has reached thermo set state.”

Protective covering must also protect from physical damage so if the protection covering does get damaged from stepping on it, dropping tools on it, birds, lawn trimmers etc.it can be replaced keeping the insulations thermal conductivity integrity and insuring the insulation system last the life of the mechanical system and avoiding the costly replacement of the insulation.

2012 & 2018 IECC Code and commentary both state that Equipment maintenance also include protection from physical damage to the pipe insulation.

The code section also requires the removal protection to shield from solar radiation that can cause degradation on of the insulation. This sometime get confused with UV protection that is under damage from “sunlight”. The additional requirement to shield against solar radiation that is more than just UV, solar radiation also includes heat. Heat is a major factor in the degradation of insulation. UV testing can be unreliable as it depends on product placement.

“Insulation materials cannot endure physical impact or are fragile to many elements, i.e. weather. Weather impact on insulation is very high. The sun enhances the transforms the insulation from thermoplast (soft) foam to thermoset (brittle) foam property. The property change also impacts the thermal conductivity of the material and consequently its performance. Protective covers become the sacrificial lamb and provide the stability in properties of the insulation. Maintenance of pipes insulation is often non-existence. Aged insulation is generally brittle, poorly reinstalled, and subject to damage to the weather”

Example of saving from protecting the insulation can be measured in Dr Kourmohammadi PE, Ph.D. CPD, CIPE, CFPE LEED AP
Paper on Protective covers which calculated the BTU and Electrical energy saving of exposed Freon lines for residential and multifamily purposes.

Freon lines exposed 3 ft to 5 ft

0.15/kwhr cost of electricity (peak demand cost can be at 0.25$/kwhr)

10 hours operation

365 days

¾" Freon line

½" insulation property 0.020227 Btu/(hr F ft)

For the California region it amounted to a $1.00 per foot annual savings

Example of cost saving average 5ft per unit in California with a population of 39 million and

If only half of the population for example had a heating and /cooling system with an average of 5ft exposed piping with degraded or no insulation, Protected pipe insulation would amount to an yearly electrical saving of $975,000,000

This is electrical saving and does not include the saving to home and building owners from not having acostly expenses of replacing the insulation for maintenance.

Bibliography: Impact and Advantages of Removable Insulation Protective Covers

Dr. “Saum” K. Nourmohammadi, PEx3, Ph.D. CPD, CIPE, CFPE,

LEED AP

2017 ASHRAE Handbook

2012, 2018 IECC Code & Commentary

Cost Impact: The code change proposal will not increase or decrease the cost of construction

There are wide varieties of removable protective coverings and are available at most supply distributors. These can be as simple as sheet metal or plastic channels, or cladding, PVC covers, Jackets, aluminum covers etc. Many covering require much less labor compared to painting or banding and they are currently being used all over the US so there no increase in cost.

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

THERMAL DISTRIBUTION EFFICIENCY (TDE). The resistance to changes in air heat as air is conveyed through a distance of air duct. TDE is a heat loss calculation evaluating the difference in the heat of the air between the air duct inlet and outlet caused by differences in temperatures between the air in the duct and the duct material. TDE is expressed as a percent difference between the inlet and outlet heat in the duct.

Revise as follows:

C403.11.1 Duct and plenum insulation and sealing (Mandatory). Supply and return air ducts and plenums shall be insulated with not less than R-6 insulation where located in unconditioned spaces and where located outside the building with not less than R-8 insulation in Climate Zones 1 through 4 and not less than R-12 insulation in Climate Zones 5 through 8. Ducts located underground beneath buildings shall be insulated as required in this section or have an equivalent thermal distribution efficiency. Underground ducts utilizing the thermal distribution efficiency method shall be listed and labeled to indicate the R-Value equivalency. Where located within a building envelope assembly, the duct or plenum shall be separated from the building exterior or unconditioned or exempt spaces by not less than R-8 insulation in Climate Zones 1 through 4 and not less than R-12 insulation in Climate Zones 5 through 8.

Exceptions:

1. Where located within equipment.
2. Where the design temperature difference between the interior and exterior of the duct or plenum is not greater than 15°F (8°C).

Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with Section 603.9 of the International Mechanical Code.
CE151-19 Part II

IECC: R202 (IRC N1101.6), R403.3.1 (IRC N1103.3.1)

Proponent: Jay Peters, Codes and Standards International, representing AQC Industries, TheBlueDuct (Jay@BuildingCodesAndStandards.com); Sharon Bonesteel, Salt River Project, representing Salt River Project (sharon.bonesteel@srpnet.com); Greg Johnson, representing Coalition for Fair Energy Codes (gjohnsonconsulting@gmail.com); David A Eisenberg, DCAT, representing DCAT (strawnet@gmail.com); Brent Ursenbach, WC-3 Inc, Inc., representing Utah Governors Office of Energy Development, representing State of Utah, Governors Office of Energy Development (brentu@wc-3.com)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

THERMAL DISTRIBUTION EFFICIENCY (TDE). The resistance to changes in air heat as air is conveyed through a distance of air duct. TDE is a heat loss calculation evaluating the difference in the heat of the air between the air duct inlet and outlet caused by differences in temperatures between the air in the duct and the duct material. TDE is expressed as a percent difference between the inlet and outlet heat in the duct.

Revise as follows:

R403.3.1 (IRC N1103.3.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter. Ducts buried beneath a building shall be insulated as required per this section or have an equivalent thermal distribution efficiency. Underground ducts utilizing the thermal distribution efficiency method shall be listed and labeled to indicate the R-value equivalency.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

Reason: This proposal was unanimously approved by the membership at the Public Comment Hearing (PCH) based on the committee's recommendation to add a product labeling provision. It received strong support from industry (NSF, the Air Conditioning Contractors of America's National Code Committee, building and energy officials and the Membership during the PCH. The CE proposal is being resubmitted as approved with absolutely no changes or edits with hope that the membership and committee will both agree again to the merit. The residential proposal has been correlated with the commercial section for consistency. The technical aspects of the proposal were verified through rigorous testing by NSF utilizing the NSF Protocol P374. The Thermal Distribution Efficiency and R-Value equivalency is currently being printed on ducts to eliminate any confusion in the field, as requested by the committee. This modification requires the duct manufacturer to list the product and label it accordingly. For example, if a duct has been tested and certified to meet an R-10 equivalency, it will indicate on the label that the Thermal Distribution Efficiency = R10 Equivalency.

BACKGROUND: For decades, ICC ES PMG LC 1014 has been the only criteria used to certify underground ducts. NSF, ICC, UL and IAPMO all recognize ICC’s LC1014, which specifies NSF P374 to calculate a duct’s Thermal Distribution Efficiency. This provisons allows for a proven, energy efficient methodology to be used, and eliminates unnecessary insulation when a duct material exhibits an equally efficient method to deliver conditioned air, saving material and energy. This is not proprietary and multiple manufacturers have certified to ICC LC 1014 and the NSF Protocol for Thermal Distribution Efficiency. TDE is only used for ducts buried...
beneath building and does not eliminate or restrict insulated ducts from their current compliance path utilizing the traditional R-value method. It is merely another path for cutting edge products to meet the intent of the code.

**Bibliography:** ICC ES Listing Criteria LC1014 Underground Ducts
NSF Protocol P374 Thermal Distribution Efficiency of Underground Ducts

**Cost Impact:** The code change proposal will decrease the cost of construction
By not requiring additional and unnecessary insulation on ducts underneath buildings, it could actually save construction costs.

Proposal # 5693

CE151-19 Part II
CE152-19
IECC: C403.11.2.3

Proponent: Brent Ursenbach, WC-3, representing State of Utah, Governors Office of Energy Development (brentu@wc-3.com)

2018 International Energy Conservation Code
Revise as follows:

C403.11.2.3 High-pressure duct systems (Mandatory). Ducts and plenums designed to operate at static pressures equal to or greater than 3 inches water gauge (747 Pa) shall be insulated and sealed in accordance with Section C403.11.1. In addition, ducts and plenums shall be leak tested in accordance with the SMACNA HVAC Air Duct Leakage Test Manual and shown to have a rate of air leakage (CL) less than or equal to 4.0 as determined in accordance with Equation 4-8.

\[
CL = \frac{F}{P^{0.65}}
\]
(Equation 4-8)
where:

\( F \) = The measured leakage rate in cfm per 100 square feet of duct surface.

\( P \) = The static pressure of the test.

Documentation shall be furnished by the designer demonstrating that representative sections totaling not less than 25 percent of the duct area have been tested and that all tested sections comply with the requirements of this section.

Reason: The designer does not perform the leak testing required by this section. Certainly the test requires documentation; however, it may be provided by the general contractor, mechanical contractor, test and balance contractor, or other qualified individuals or organizations, as approved by the AHJ.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal simply removes the designer as the sole provider of duct testing documentation. The testing requirements remain unchanged.
2018 International Energy Conservation Code

C403.11.3 Piping insulation (Mandatory). Piping serving as part of a heating or cooling system shall be thermally insulated in accordance with Table C403.11.3.

Exceptions:

1. Factory-installed piping within HVAC equipment tested and rated in accordance with a test procedure referenced by this code.
2. Factory-installed piping within room fan-coils and unit ventilators tested and rated according to AHRI 440 (except that the sampling and variation provisions of Section 6.5 shall not apply) and AHRI 840, respectively.
3. Piping that conveys fluids that have a design operating temperature range between 60°F (15°C) and 105°F (41°C).
4. Piping that conveys fluids that have not been heated or cooled through the use of fossil fuels or electric power.
5. Strainers, control valves, and balancing valves associated with piping 1 inch (25 mm) or less in diameter.
6. Direct buried piping that conveys fluids at or below 60°F (15°C).
7. In radiant heating systems, sections of piping intended by design to radiate heat.

Reason: Why is the proposed code change needed?
The table insulation requirements could be misinterpreted to require insulation on piping used for radiant heating, which would be counterproductive to how radiant heat systems work. This change clarifies that active sections of piping used for radiant heat do not require insulation.

Why is the proposed code change a reasonable solution? It clarifies the table requirements

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The Intent of this change is to not insulate radiant heating system piping to reduce the heat it provides to a space. That is the intent of a Radiant system. This change will save money by allowing the system to work as designed.
Add new definition as follows:

**Best Efficiency Point.** The pump hydraulic power operating point, consisting of both flow and head conditions, that results in the maximum efficiency.

**PEICL.** The pump energy index for a constant load (hp) (kW).

**PERCL.** The pump energy rating for a constant load (hp) (kW), determined in accordance with either testing for bare pumps, pumps sold with single-phase induction motors, and pumps sold with drivers other than electric motors, or testing for pumps sold with motors and rated using the testing-based approach, or testing for pumps sold with motors and rated using the calculation-based approach.

**PERSTD.** The PERCL for a pump that is minimally compliant with Subpart Y of 10 CFR, Part 431, with the same flow and specific speed characteristics as the tested pump (hp/kW).

**PEIVL.** The pump energy index for a variable load.

**PERVL.** The pump energy rating for a variable load (hp) (kW) determined in accordance with testing for pumps sold with motors and continuous or non-continuous controls rated using the testing-based approach, or testing for pumps sold with motors and continuous controls rated using the calculation-based approach.

**PUMP** Equipment designed to move liquids that does or does not include entrained gases, free solids, and totally dissolved solids by physical or mechanical action and includes a bare pump and, if included by the manufacturer at the time of sale, mechanical equipment, driver, and controls.

**Clean Water Pump.** A device that is designed for use in pumping water with a maximum non-absorbent free solid content of 0.016 pounds per cubic foot (0.26 kilograms per cubic meter), and with a maximum dissolved solid content of 3.1 pounds per cubic foot (50 kilograms per cubic meter), provided that the total gas content of the water does not exceed the saturation volume, and disregarding any additives necessary to prevent the water from freezing at a minimum of 14°F (-10°C).

**End Suction Close-Coupled (ESCC) Pump.** A close-coupled, dry rotor, end suction device that has a shaft input power greater than or equal to 1.0 horsepower (0.75 kW) and less than or equal to 200 horsepower (150 kW) at its Best Efficiency Point (BEP) and full impeller diameter and that is not a dedicated-purpose pool pump. It is also a single-stage, rotodynamic pump in which the liquid enters the bare pump in the direction parallel to the impeller shaft and on the side opposite the bare pump's driver-end, and is then discharged through a volute in a plane perpendicular to the shaft.

**End Suction Frame Mounted/Own Bearings (ESFM) Pump.** A mechanically-coupled, dry rotor, end suction device that has a shaft input power greater than or equal to 1.0 horsepower (0.75 kW) and less than or equal to 200 horsepower (150 kW) at its Best Efficiency Point (BEP) and full impeller diameter and that is not a dedicated-purpose pool pump. It is also a single-stage, rotodynamic pump in which the liquid enters the bare
pump in a direction parallel to the impeller shaft and on the side opposite the bare pump's driver-end, and is then discharged through a volute in a plane perpendicular to the shaft.

**In-Line (IL) Pump.** A device that is either a twin-head pump or a single-stage, single-axis flow, dry rotor, rotodynamic pump that has a shaft input power greater than or equal to 1.0 horsepower (0.75 kW) and less than or equal to 200 horsepower (150 kW) at its *Best Efficiency Point (BEP)* and full impeller diameter, in which liquid is discharged through a volute in a plane perpendicular to the shaft. Such pumps do not include pumps that are mechanically coupled or close-coupled, have a pump power output that is less than or equal to 5.0 horsepower (3.7 kW) at its *Best Efficiency Point (BEP)* at full impeller diameter, and are distributed in commerce with a horizontal motor.

**Radially Split, Multi-Stage, Vertical, In-Line Diffuser Casing (RSV) Pump.** A device that is a vertically suspended, multi-stage, single axis flow, dry rotor, rotodynamic pump complies with all of the following:
1. Has a shaft input power greater than or equal to 1.0 horsepower (0.75 kW) and less than or equal to 200 horsepower (150 kW) at its *Best Efficiency Point (BEP)* and full impeller diameter and at the number of stages required for testing,
2. In which liquid is discharged in a place perpendicular to the impeller shaft.
3. For which each stage or bowl, consists of an impeller and diffuser.
4. For which no external part of such a pump is designed to be submerged in the pumped liquid.

**Submersible Turbine (ST) Pump.** A device that is a single-stage or multi-stage, dry rotor, rotodynamic pump that is designed to be operated with the motor and stage(s) fully submerged in the pumped liquid; that has a shaft input power greater than or equal to 1.0 horsepower (0.75 kW) and less than or equal to 200 horsepower (150 kW) at its *Best Efficiency Point (BEP)* and full impeller diameter and at the number of stages required for testing; and in which each stage of this pump consists of an impeller and diffuser, and liquid enters and exits each stage of the bare pump in a direction parallel to the impeller shaft.

**Add new text as follows:**

**C403.13 Pumping equipment performance requirements (Mandatory).** Clean water pumps meeting the following criteria shall meet the efficiency requirements shown in Table C403.13: when tested and rated in accordance with the applicable test procedure.

MIL-P-17840-D-2018: Pump, Centrifugal, Close Coupled, Navy Standard for Use on Naval Ships

Reason: In January, 2016, the U.S. Department of Energy published a final rule for energy conservation standards for commercial and industrial clean water pumps that will go into effect as of January 27, 2020. This addendum provides a new table of information about the new efficiency requirements. It also provides new definitions that are needed to accompany the table. This proposal will have an energy savings impact in those buildings that use clean water pumps. According to the DOE analysis, the simple payback for the pumps ranges from 0.8 to 3.1 years.

This information will help energy code officials ensure that installed clean water pumps are meeting the federal efficiency standards on or after January 2020.

The formula for efficiency is shown below (and is copied from the DOE Technical Support Document, December 2015):

\[ \eta_{pump, STD} = -0.8500 \times \ln(Q)^2 - 0.3800 \times \ln(Ns) \times \ln(Q) - 11.480 \times \ln(Ns)^2 + 17.800 \times \ln(Q) + 179.80 \times \ln(Ns) - (C + 555.60) \]

Where:

Q = flow at BEP at full impeller diameter and nominal speed (gpm),

Ns = specific speed at 60 Hz and calculated using U.S. customary units, and

C = a constant that is set for the surface, which is set based on the speed of rotation and equipment type of the pump model.

“The minimally compliant PER is unique to each pump model and is a function of each pump model’s flow at BEP and specific speed. This function is an equation that represents the attainable hydraulic efficiency of pumps for a given flow and specific speed. All of the terms of the polynomial function are the same for all efficiency levels and classes of pumps for the DOE analysis, except for the constant parameter. This parameter, the “C-value,” is unique for each combination of equipment class and efficiency level. Changing the C-value moves the otherwise fixed-shape surface to higher or lower efficiency. Because the function was developed to represent the inherent pump efficiency trends as flow and specific speed change, the C-value can be used to define an efficiency level, which is equally stringent for all pumps across the scope of flow and specific speed. By adjusting the C-value, DOE can establish different efficiency levels that represent different efficiency percentiles.

For this final rule the three-dimensional polynomial efficiency equation discussed in the previous paragraph is
based on the EU minimum efficiency index (MEI) equation but is adapted to account for the use of English units and the 60 Hz electrical input power found in the United States. The converted equation is shown in Equation 5.1.

**Cost Impact:** The code change proposal will increase the cost of construction.
Costs will increase due to the incremental cost increases associated with the new efficiency standards for clean water pumps. Based on analysis performed by the US Department of Energy, the incremental costs of increased efficiency of the federally regulated clean water pumps will be recovered with 3.1 years.

**Analysis:** A review of the standards proposed for inclusion in the code, 10 CFR part 50, MIL–P–17639F, MIL–P–17881D, MIL–P–17840C, MIL–P–18682D, and MIL–P–18472G, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 4871

CE154-19
CE156-19
IECC: C404.2.1

Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

C404.2.1 High input service water-heating systems. Gas-fired water-heating equipment installed in new buildings shall be in compliance with this section. Where a singular piece of water-heating equipment serves the entire building and the input rating of the equipment is 1,000,000 Btu/h (293 kW) or greater, such equipment shall have a thermal efficiency, $E_t$, of not less than 90-92 percent. Where multiple pieces of water-heating equipment serve the building and the combined input rating of the water-heating equipment is 1,000,000 Btu/h (293 kW) or greater, the combined input-capacity-weighted-average thermal efficiency, $E_t$, shall be not less than 90 percent.

Exceptions:

1. Where not less than 25 percent of the annual service water-heating requirement is provided by on-site renewable energy or site-recovered energy, the minimum thermal efficiency requirements of this section shall not apply.
2. The input rating of water heaters installed in individual dwelling units shall not be required to be included in the total input rating of service water-heating equipment for a building.
3. The input rating of water heaters with an input rating of not greater than 100,000 Btu/h (29.3 kW) shall not be required to be included in the total input rating of service water-heating equipment for a building.

Reason: Section C404.2.1 addresses not just typical commercial service water heating loads like laundries; it also addresses larger boilers used for central heating in R-occupancies. Water heating is one of the largest loads in R-1 (hotels) and R-2 (multifamily) occupancies. It composes around 25-35% of the total building load in typical multifamily buildings. This makes this an important provision of the energy code. However, while federal minimums and boiler markets have advanced, this provision has not been updated. Therefore, the performance premium that this provision requires has eroded over time.

This proposal includes a modest increase in the efficiency requirement for C404.2.1 from 90% $E_t$ to 92% $E_t$. This improvement can be met without making major technology shifts since achieving a 90% $E_t$ already generally requires condensing technology. Of the 2782 boilers that meet the 1,000,000 Btu/h threshold, 852 meet the existing 90% requirement and 792 meet a requirement of 92% $E_t$, so market availability will be minimally impacted.

Savings for this proposal are significant. Using the high-rise multifamily model developed by Pacific Northwest National Lab’s determination study of the 2015 IECC, savings from this proposal would range from 2.3%-4.0% whole-building energy savings depending on climate zone. While 2015 is not exactly the same as 2018, the water heating provisions are very similar so the savings should be reasonably representative of savings for 2018.

Cost Impact: The code change proposal will increase the cost of construction.
This proposal could have a limited impact on cost. However, it only eliminates about 7% of the boilers that meet the existing requirement, so the impact should be minimal.
C404.4 Insulation of piping. Piping from a water heater to the termination of the heated water fixture supply pipe. The following piping shall be insulated to levels indicated in accordance with Table C403.11.3. On both the inlet and outlet piping of a storage water heater or heated water storage tank, the piping to a heat trap or the first 8 feet (2438 mm) of piping, whichever is less, shall be insulated. Piping that is heat traced shall be insulated in accordance with Table C403.11.3 or the heat trace manufacturer's instructions. Tubular pipe insulation shall be installed in accordance with the insulation manufacturer's instructions. Pipe insulation shall be continuous except where the piping passes through a framing member. The minimum insulation thickness requirements of this section shall not supersede any greater insulation thickness requirements necessary for the protection of piping from freezing temperatures or the protection of personnel against external surface temperatures on the insulation.

**Exception:** Tubular pipe insulation shall not be required on the following:

1. Recirculating system piping, other than the cold-water piping of demand recirculating systems, including the supply and return piping of a circulating tank type water heater.
2. The first 8 feet of outlet piping for a constant-temperature non-recirculating storage system.
3. The first 8 feet of branch piping connected to a recirculated, heat-traced, or impedance heated piping.
4. The inlet piping between the storage tank and a heat trap in a non-recirculating storage system.

Piping that is externally heated, such as heat trace or impedance heating, shall be insulated to levels indicated in Table C403.11.3 or the heat trace manufacturer's instructions.

1. The tubing from the connection at the termination of the fixture supply piping to a plumbing fixture or plumbing appliance.
2. Valves, pumps, strainers and threaded unions in piping that is 1 inch (25 mm) or less in nominal diameter.
3. Piping from user-controlled shower and bath mixing valves to the water outlets.
4. Cold-water piping of a demand recirculation water system.
5. Tubing from a hot drinking-water heating unit to the water outlet.
6. Piping at locations where a vertical support of the piping is installed.
7. Piping surrounded by building insulation with a thermal resistance (R-value) of not less than R-3.

**Reason:** The 2015 IECC established new insulation requirements for hot water piping. The code now requires that every inch of concealed hot water piping be insulated with minimum 1-inch thick insulation. This now includes even non-circulated hot water piping and branches. As the plumbing industry wakes up to the new requirements, they are proving to be excessive, expensive, and unworkable. The level of hot water insulation now far exceeds that found in ASHRAE 90.1-2016. Although it has always made sense to insulate the hot water mains and returns of recirculating systems, there is little to gain by insulating non-circulated branch piping, which tends to cool rather quickly due to infrequent demand – whether insulated or not. Plumbing hot water pipes are typically 110-120°F, and are generally installed in interior wall cavities averaging 70°F. And much of today’s water piping is plastic – CPVC or PEX - with insulative properties...
that greatly exceed that of copper.

The additional cost of insulating all of these non-circulated branches far outweighs any perceived payback. Recirculating loops are typically located in roomy ceiling spaces; branch piping usually runs inside cramped 3-1/2-inch frame walls. With insulated pipe measuring 2-1/2 to 3 inches O.D., installation can be difficult and time-consuming inside congested walls (and impossible on single- or double-furred block walls.) The extra cost in labor and materials to insulate CPVC hot water pipes running inside a wall can be several times the cost of the pipe itself. Often there is just no way to comply with the code. Multi-family buildings are especially affected.

This proposal restores the actual ASHRAE 90.1 requirements. Hot water recirculating piping would be insulated. So would the first 8 feet of branch piping emanating from the circulating loop. So would the first 8 feet of outlet piping from the heated water source. This amount of hot water insulation is actually greater than previous ASHRAE standards. And it achieves a more reasonable balance between energy savings and installation costs.

I urge the committee to carefully consider the real world impact of the current hot water insulation requirements and to approve this sensible fix.

**Cost Impact:** The code change proposal will decrease the cost of construction
By eliminating unnecessary hot water branch piping insulation, this proposal will reduce the cost of plumbing by $200 – $300 per unit for a typical two-bathroom apartment.
2018 International Energy Conservation Code

Revise as follows:

C404.5.2.1 Water volume determination. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds between the nearest source of heated water and the termination of the fixture supply pipe. The volume in the piping shall be determined from the “Volume” column in Table C404.5.1, C404.5.1 or from Table E202.1 of the International Plumbing Code. The volume contained within fixture shutoff valves, within flexible water supply connectors to a fixture fitting and within a fixture fitting shall not be included in the water volume determination. Where heated water is supplied by a recirculating system or heat-traced piping, the volume shall include the portion of the fitting on the branch pipe that supplies water to the fixture.

Reason: Table E202.1 in the IPC, "Internal Volume of Various Water Distribution Tubing" is well suited for this calculation and should be specifically included as an option in calculations for the section. The table is shown below.

</table>

For SI: 1 ounce = 0.030 liter.

Bibliography: None

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The addition of the method of calculation is not expected to increase or decrease the cost of construction, it is simply a more accurate method for determining volume.

Staff Analysis: The table referenced is in Appendix E of the IPC.
CE159-19 Part I

PART I — IECC: C404.6.1, C404.7

PART II — IECC: R403.5.1.1 (IRC N1103.5.1.1), R403.5.2 (IRC N1103.5.2)

Proponent: Anthony Floyd, City of Scottsdale, representing City of Scottsdale (afloyd@scottsdaleaz.gov)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC- COMMERCIAL COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Energy Conservation Code

Revise as follows:

C404.6.1 Circulation systems. Heated-water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is not a demand for hot water. The controls shall limit the temperature of the water entering the cold-water piping to not greater than 104°F (40°C).

C404.7 C404.6.1.1 Demand recirculation controls. Demand recirculation water systems shall have controls that comply with both of the following:

1. The controls shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.

2. The controls shall limit the temperature of the water entering the cold-water piping to not greater than 104°F (40°C).
CE159-19 Part II

IECC: R403.5.1.1 (IRC N1103.5.1.1), R403.5.2 (IRC N1103.5.2)

Proponent: Anthony Floyd, City of Scottsdale, representing City of Scottsdale (afloyd@scottsdaleaz.gov)

2018 International Energy Conservation Code

Revise as follows:

R403.5.1.1 (IRC N1103.5.1.1) Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermosyphon circulation systems shall be prohibited. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water. The controls shall limit the temperature of the water entering the cold-water piping to not greater than 104°F (40°C).

R403.5.2 (IRC N1103.5.2) R403.5.1.1.1 (IRC N1103.5.1.1.1) Demand recirculation water systems. Demand recirculation water systems shall have controls that comply with both of the following:

1. The controls shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The controls shall limit the temperature of the water entering the cold water piping to not greater than 104°F (40°C).

Reason: This code change clarifies the requirements for heated water circulation and demand recirculation systems. Section R403.5.2 - 'Demand recirculation water systems' is moved and renumbered as a subsection to R403.5.1.1 - 'Circulation systems' because demand recirculation is a type of 'circulation system' with specific demand-initiated control requirements. The temperature limit for cold-water return piping, item 2 of 'Demand recirculation water systems' is relocated to the body of section R403.5.1.1 (circulation systems) because this provision pertains to all heated water circulation systems that use cold-water piping as a return to the water-heating equipment.

This code change clarifies the intent of this section for the energy efficient delivery of hot water by correlating the existing provisions for circulation and demand recirculation water systems. These provisions are only applicable when heated water circulation and demand recirculation systems are installed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change does not add any new requirements.

Proposal # 5417
CE160-19 Part I

PART I — IECC: Part I: C404.9.1, C404.9.3, C404.10
IECC Part II: R403.10 (N1103.10), R403.10.2 (N1103.10.2), R403.10.3(N1103.10.3), R403.12 (N1103.12)

PART II — IECC: R403.10 (IRC N1103.10), R403.10.1 (IRC N1103.10.1), R403.10.3 (IRC N1103.10.3), R403.12 (IRC N1103.12)

Proponent: Jennifer Hatfield, representing Association of Pool & Spa Professionals (jen@jhattfieldandassociates.com)

2018 International Energy Conservation Code

C404.9 Energy consumption of pools and permanent spas (Mandatory). The energy consumption of pools and permanent spas shall be controlled by the requirements in Sections C404.9.1 through C404.9.3.

Revise as follows:

C404.9.1 Heaters. The electric power to all heaters shall be controlled by a readily accessible on-off switch that is an integral part of the heater, mounted on the exterior of the heater or external to and within 3 feet (914 mm) of the heater in a location with ready access. Operation of such switch shall not change the setting of the heater thermostat. Such switches shall be in addition to a circuit breaker for the power to the heater. Gas-fired heaters shall not be equipped with continuously burning ignition pilots.

C404.9.2 Time switches. Time switches or other control methods that can automatically turn off and on heaters and pump motors according to a preset schedule shall be installed for heaters and pump motors. Heaters and pump motors that have built-in time switches shall be in compliance with this section.

Exceptions:

1. Where public health standards require 24-hour pump operation.
2. Pumps that operate solar- and waste-heat-recovery pool heating systems.

C404.9.3 Covers. Outdoor heated pools and outdoor permanent spas shall be provided with a vapor-retardant cover or other approved vapor-retardant means.

Exception: Where more than 75-70 percent of the energy for heating, computed over an operating season of not fewer than 3 calendar months, is from site-recovered energy such as from a heat pump or on-site renewable solar energy system source, covers or other vapor-retardant means shall not be required.

C404.10 Energy consumption of portable Portable spas (Mandatory). The energy consumption of electric-powered portable spas shall be controlled by the requirements of APSP 14.

Proposal # 5571
CE160-19 Part II

IECC: R403.10 (IRC N1103.10), R403.10.1 (IRC N1103.10.1), R403.10.3 (IRC N1103.10.3), R403.12 (IRC N1103.12)

Proponent: Jennifer Hatfield, representing Association of Pool & Spa Professionals (jen@jhatfieldandassociates.com)

2018 International Energy Conservation Code

Revise as follows:

R403.10 (IRC N1103.10) Pools Energy consumption of pools and permanent spa energy consumption spas (Mandatory). The energy consumption of pools and permanent spas shall be controlled by the requirements in accordance with Sections R403.10.1 through R403.10.3.

R403.10.1 (IRC N1103.10.1) Heaters. The electric power to heaters shall be controlled by a readily accessible on-off switch that is an integral part of the heater, mounted on the exterior of the heater or external to and within 3 feet (914 mm) of the heater. Operation of such switch shall not change the setting of the heater thermostat. Such switches shall be in addition to a circuit breaker for the power to the heater. Gas-fired heaters shall not be equipped with continuously burning ignition pilots.

R403.10.2 (IRC N1103.10.2) Time switches. Time switches or other control methods that can automatically turn off and on heaters and pump motors according to a preset schedule shall be installed for heaters and pump motors. Heaters and pump motors that have built-in time switches shall be in compliance with this section.

Exceptions:

1. Where public health standards require 24-hour pump operation.
2. Pumps that operate solar- and waste-heat-recovery pool heating systems.

R403.10.3 (IRC N1103.10.3) Covers. Outdoor heated pools and outdoor permanent spas shall be provided with a vapor-retardant cover or other approved vapor-retardant means.

Exception: Where more than 75% of the energy for heating, computed over an operation season of not less than three calendar months, is from a heat pump or an on-site renewable solar energy system source, covers or other vapor-retardant means shall not be required.

R403.11 (IRC N1103.11) Portable spas (Mandatory). The energy consumption of electric-powered portable spas shall be controlled by the requirements of APSP-14.

R403.12 (IRC N1103.12) Residential pools and permanent residential spas (Mandatory). Residential swimming pools and permanent residential spas that are accessory to detached one- and two-family dwellings and townhouses three stories or less in height above grade plane and that are available only to the household and its guests shall be controlled in accordance with the requirements of APSP 15.

Reason: This proposal aligns the energy efficiency provisions of the IECC for residential pools, spas and portable spas (hot tubs) with those found in the 2018 International Swimming Pool & Spa Code. A similar proposal has been submitted to ensure IECC commercial provisions are also aligned with the ISPSC pool & spa energy efficiency provisions found within Section 303. Without this proposal a jurisdiction who adopts both the IECC and ISPSC will have conflicting code requirements addressing covers for outdoor heated pools and outdoor permanent spas. Therefore, this proposal is simply
making the exception language for a vapor-retardant cover consistent with what exists in the ISPSC. The ISPSC has always used a 70% threshold computed over an operation season – there is no minimum operating season in the ISPSC due to the fact depending on the part of the country, an operating season can be from as little as a few months to an entire year.

The reality is after the pool or spa is installed and final inspection has occurred, there is no way to ensure a cover is being put back on after every use; therefore, encouraging use of more energy efficient heating systems by providing an exception from the vapor-retardant cover provides a greater chance of energy savings. Having consistent language on how that exception is intended to work in the ISPSC, IECC Commercial and IECC Residential is critical.

The proposed change also adds in the word “mandatory” in section R403.12 for consistency with R403.10 and R403.11, as all provisions listed are mandatory with no other alternative. Further, R403.12 requires residential pools and permanent spas to meet the ANSI/APSP/ICC 15 Standard.

The remaining code proposal language is simply cleanup to reflect consistent verbiage used between the two I-codes, because the pool & spa energy efficiency language is not completely consistent when comparing the IECC to the ISPSC. Further, within the IECC the commercial and residential provisions slightly differ as well. Although the remaining differences are minor and may not affect the intent, eliminating differences do lessen the chance of interpretation errors.

By adopting this code change, a jurisdiction that adopts both the ISPSC and IECC, which is increasingly more likely and already exists in many cases (over 20 states and 160 localities have adopted the ISPSC), will not be left with conflicting code requirements. Rather, they will co-exist by providing consistent requirements that follow the original intent.

**Bibliography:** 2018 ISPSC, Section 303 and 2018 IECC, Section C404.9

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change should not affect the cost of construction but for any costs associated with differing provisions found within the current ISPSC and IECC editions, if the change is not adopted. The proposal simply ensures the IECC has consistent energy efficiency requirements for residential pools and spas from what is found in the ISPSC.

Proposal # 5558
2018 International Energy Conservation Code

Revise as follows:

GENERAL LIGHTING. Lighting that provides a substantially uniform level of illumination throughout an area. General lighting shall not include decorative lighting or lighting that provides a dissimilar level of illumination to serve a specialized application or feature within such area - a space.

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption.

Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or

C405.2.3 Daylight-responsive controls. Daylight-responsive controls complying with Section C405.2.3.1 shall be provided to control the electric lights general lighting within daylight zones in the following spaces:

1. Spaces with a total of more than 150 watts of general lighting within sidelit zones complying with Section C405.2.3.2 General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4.

2. Spaces with a total of more than 150 watts of general lighting within toplit zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance (LPA_{adj}) calculated in accordance with Equation 4-9

\[
LPA_{adj} = \left[ \frac{LPA_{norm}}{TBFA} \times (1.0 - 0.4 \times UDZFA / TBFA) \right]
\]

(Equation 4-9)

where:
LPA_{adj} = Adjusted building interior lighting power allowance in watts.

LPA_{norm} = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.

UDZFA = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.

TBFA = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

**Reason:** Users need a clear definition of the term general lighting, which is currently used at least 14 times in Section C405, but nowhere else in the code. The term general lighting establishes many of the lighting controls requirements in the code, so it is important that we have a meaning for this term which is clear and concise in all instances.

The current definition of general lighting includes technical requirements, which should not be located there by editorial convention. This proposal would relocate those technical requirements to C405.1, so that they will be applicable throughout Section C405.

Once this definition is updated, redundant provisions of C405.2.3 can be deleted.

The change from “electric” lighting to “general” lighting in the first sentence may be seen as limiting the scope of lighting controls requirements, but it is important that we use consistent terminology throughout this section of the code. Furthermore, we believe that daylight responsive controls requirements should be limited to general lighting. Daylight responsive control of other lighting, such as display and accent lighting, task lighting, lighting in sleeping units, etc. complex and problematic.

**Cost Impact:** The code change proposal will decrease the cost of construction

This proposal would slightly reduce the scope of daylight responsive controls requirements, which would slightly reduce the cost of construction.
CE162-19

IECC: C405.1, C405.1.1 (New), C405.1.2 (New)

Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption shall comply with this section. Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2.

Add new text as follows:

C405.1.1 Lighting for dwelling units. No less than 90 percent of the permanently installed lighting serving dwelling units shall be provided by lamps with an efficacy of not less than 65 lm/W or luminaires with an efficacy of not less than 45 lm/W, or shall comply with Sections C405.2.4 and C405.3.

C405.1.2 Lighting for refrigerated applications. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2.

Reason: The current language refers lighting in dwelling units to the lighting requirements in the residential section. The referenced residential code sections include a requirement that 90% of the lighting be provided by "high efficacy lamps." There are a handful of issues with the existing code requirements:

1. The definition of "high efficacy lamps" has not been updated to reflect the changes in the market due to increased federal minimums and greater availability/affordability of LED lighting. As a result the code has actually become less stringent as the baseline for lighting equipment is raised.
2. The categories in the definition of “high efficacy lamps” in the residential code is an artifact of incandescent and early compact fluorescent lamp wattages. As lamps have gotten more efficient, the higher wattage categories have become less meaningful. Even a “100W equivalent” LED lamp and “60W equivalent” CFL lamps generally uses 15W or less, which is the bottom category in the existing definition. As a result, the categories have become largely meaningless.
3. The definition is for high efficacy lamps. However, with the proliferation of LED lighting, the market is increasingly utilizing luminaires with integrated LEDs, which are not really lamps. This prevents this high-efficiency lighting solution from being used to meet the high efficacy requirement.

This proposal solves these problems by replacing the reference to the residential lamp efficacy requirements with built-in lighting requirements. Like the existing lighting requirement, this proposal would require that 90% of the lighting be provided by higher performance lighting, but it replaces the reference to “high efficacy lamps” with a built-in efficacy requirement. This requirement establishes minimums for both lamps and luminaires so that it is relevant to the current lighting market without the wattage bins that are no longer relevant to current technologies. The efficacy levels are widely available and are low enough that products with a wide array of color temperatures and CRI's can meet the requirement, providing lighting designers and customers with flexibility.
The proposal also structures the section for greater clarity. Requirements for dwelling unit lighting and refrigerated application have been somewhat shoe-horned into C405.1, leaving the section bloated and without focus. This proposal breaks the requirements for dwelling unit lighting and refrigerated applications into standalone sub-sections for greater clarity.

When modeled against IECC-2015 using the mid-rise and high-rise prototypes developed by Pacific Northwest National Lab for code determination studies, whole-building energy savings ranged from 0.1-0.5% and whole-building electricity savings ranged from 5.3-6.5%. While the 2018 IECC is not exactly the same baseline as 2015, the lighting requirements did not change and these results give a reasonable approximation of savings. Based on U.S. DOE studies, the cost savings by replacing all of the CFLs with higher efficacy LED lighting saves approximately $6 per year per dwelling unit in overall regulated energy costs.

**Cost Impact:** The code change proposal will increase the cost of construction

This change could potentially increase the cost of construction because it requires higher efficacy lighting (lamps and/or fixtures), which will likely eliminate some lower-end CFL options and/or push builders to newer LED technologies. However, the cost of LEDs has been steadily declining over the last several years and is expected to continue to decline. Based on an analysis by the U.S. Department of Energy’s Building Energy Codes Program conducted during the 2018 IECC Code Development cycle, the estimated and projected prices for LEDs were $4.84 per lamp compared to CFLs at $3.10 per lamp. However, the rapid expansion of the LED lighting market has changed the economics. A spot check of Home Depot in early 2019 showed that a warm white, 60W equivalent A-lamp is as low as $1.24 for both CFL and LED when purchased in packs. And, LEDs are actually cheaper than CFLs at some sources. At 1000bulbs.com, an online retailer, the same lamps are $1.79/bulb for CFL and $0.99 for LED. Therefore, this code change may actually reduce the cost of construction.

Proposal # 5147

CE162-19
2018 International Energy Conservation Code

Revise as follows:

**GENERAL LIGHTING.** Lighting that provides a substantially uniform level of illumination throughout an area. General lighting shall not include decorative lighting or lighting that provides a dissimilar level of illumination to serve a specialized application or feature within such area. a space.

C405.1 General (Mandatory). This section covers lighting system controls, the maximum lighting power for interior and exterior applications and electrical energy consumption. Dwelling units within multifamily buildings shall comply with Section R404.1. All other dwelling units shall comply with Section R404.1, or with Sections C405.2.4 and C405.3. Sleeping units shall comply with Section C405.2.4, and with Section R404.1 or C405.3. Lighting installed in walk-in coolers, walk-in freezers, refrigerated warehouse coolers and refrigerated warehouse freezers shall comply with the lighting requirements of Section C403.10.1 or C403.10.2.

*General lighting* shall consist of all lighting included when calculating the total connected interior lighting power in accordance with Section C405.3.1 and which does not require specific application controls in accordance with Section C405.2.4.

C405.2.1 Occupant sensor controls. Occupant sensor controls shall be installed to control lights in the following space types:

1. Classrooms/lecture/training rooms.
2. Conference/meeting/multipurpose rooms.
3. Copy/print rooms.
4. Lounges/breakrooms.
5. Enclosed offices.
6. Open plan office areas.
7. Restrooms.
8. Storage rooms.
9. Locker rooms.
10. Other spaces 300 square feet (28 m²) or less that are enclosed by floor-to-ceiling height partitions.
11. Warehouse storage areas.

**Exception:** Luminaires which are required to have specific application controls in accordance with C405.2.4.

C405.2.2 Time-switch controls. Each area of the building that is not provided with occupant sensor controls complying with Section C405.2.1.1 shall be provided with time-switch controls complying with Section C405.2.2.1.

**Exceptions**

1. Luminaires which are required to have specific application controls in accordance with
C405.2.4

2. Where a manual control provides light reduction in accordance with Section C405.2.2.2, time-switch controls shall not be required for the following:

1. Spaces where patient care is directly provided.
2. Spaces where an automatic shutoff would endanger occupant safety or security.
3. Lighting intended for continuous operation.
4. Shop and laboratory classrooms.

C405.2.4 Specific application controls. Specific application controls shall be provided for the following:

1. The following lighting shall be controlled by an occupant sensor complying with Section C405.2.1.1 or a time-switch control complying with Section C405.2.2.1. In addition, a manual control shall be provided to control such lighting separately from the general lighting in the space:

   1.1 Luminaires for which additional lighting power is claimed in accordance with C405.3.2.2.1.
   1.2 Display and accent.
   1.3 Lighting in display cases.
   1.4 Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting.
   1.5 Lighting equipment that is for sale or demonstration in lighting education.
   1.6 Display lighting for exhibits in galleries, museums and monuments that is in addition to general lighting.

2. Sleeping units shall have control devices or systems that are configured to automatically switch off all permanently installed luminaires and switched receptacles within 20 minutes after all occupants have left the unit.

Exceptions:

1. Lighting and switched receptacles controlled by card key controls.
2. Spaces where patient care is directly provided.

3. Permanently installed luminaires within dwelling units shall be provided with controls complying with Section C405.2.1.1 or C405.2.2.2.

4. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a time switch control complying with Section C405.2.2.1 that is independent of the controls for other lighting within the room or space.

5. Task lighting for medical and dental purposes that is in addition to general lighting shall be provided with a manual control.

C405.3.1 Total connected interior lighting power. The total connected interior lighting power shall be determined in accordance with Equation 4-10.

\[ TCLP = [LVL + BLL + LED + TRK + Other] \]

(Equation 4-10)

where:

\( TCLP \) = Total connected lighting power (watts).

\( LVL \) = For luminaires with lamps connected directly to building power, such as line voltage lamps, the rated
wattage of the lamp.

**BLL** = For luminaires incorporating a ballast or transformer, the rated input wattage of the ballast or transformer when operating that lamp.

**LED** = For light-emitting diode luminaires with either integral or remote drivers, the rated wattage of the luminaire.

**TRK** = For lighting track, cable conductor, rail conductor, and plug-in busway systems that allow the addition and relocation of luminaires without rewiring, the wattage shall be one of the following:

1.  The specified wattage of the luminaires, but not less than 8 W per linear foot (25 W/lin m).
2.  The wattage limit of the permanent current-limiting devices protecting the system.
3.  The wattage limit of the transformer supplying the system.

Other = The wattage of all other luminaires and lighting sources not covered previously and associated with interior lighting verified by data supplied by the manufacturer or other approved sources. The connected power associated with the following lighting equipment and applications is not included in calculating total connected lighting power.

1.  Television broadcast lighting for playing areas in sports arenas.
2.  Emergency lighting automatically off during normal building operation.
3.  Lighting in spaces specifically designed for use by occupants with special lighting needs, including those with visual impairment and other medical and age-related issues.
4.  Casino gaming areas.
5.  Mirror lighting in dressing rooms.
6.  Task lighting for medical and dental purposes that is in addition to _general lighting_ and controlled by an independent control device.
7.  Display lighting for exhibits in galleries, museums and monuments that is in addition to _general lighting_ and controlled by an independent control device.
8.  Lighting for theatrical purposes, including performance, stage, film production and video production.
10. Lighting integral to equipment or instrumentation and installed by the manufacturer.
11. Task lighting for plant growth or maintenance.
12. Advertising signage or directional signage.
13. Lighting for food warming.
14. Lighting equipment that is for sale.
15. Lighting demonstration equipment in lighting education facilities.
16. Lighting approved because of safety considerations.
17. Lighting in retail display windows, provided that the display area is enclosed by ceiling-height partitions.
18. Furniture-mounted supplemental task lighting that is controlled by automatic shutoff.
19. Exit signs.

**C405.3.2.2.1 Additional interior lighting power.** Where using the Space-by-Space Method, an increase in the interior lighting power allowance is permitted for specific lighting functions. Additional power shall be permitted only where the specified lighting is installed and automatically controlled separately from the general lighting, to be turned off during nonbusiness hours, controlled in accordance with C405.2.4. This additional power shall be used only for the specified luminaires and shall not be used for any other purpose. An increase in the interior...
lighting power allowance is permitted in the following cases:

1. For lighting equipment to be installed in sales areas specifically to highlight merchandise, the additional lighting power shall be determined in accordance with Equation 4-11. Additional interior lighting power allowance = 1000 W + (Retail Area 1 x 0.45 W/ft²) + (Retail Area 2 x 0.45W/ft²) + (Retail Area 3 x 1.05 W/ft²) + (Retail Area 4 x 1.87 W/ft²)

For SI units:

Additional interior lighting power allowance = 1000 W + (Retail Area 1 x 4.8 W/m²) + (Retail Area 2 x 4.84 W/m²) + (Retail Area 3 x 11 W/m²) + (Retail Area 4 x 20 W/m²)

(Equation 4-11)

where:

Retail Area 1 = The floor area for all products not listed in Retail Area 2, 3 or 4.

Retail Area 2 = The floor area used for the sale of vehicles, sporting goods and small electronics.

Retail Area 3 = The floor area used for the sale of furniture, clothing, cosmetics and artwork.

Retail Area 4 = The floor area used for the sale of jewelry, crystal and china.

Exception: Other merchandise categories are permitted to be included in Retail Areas 2 through 4, provided that justification documenting the need for additional lighting power based on visual inspection, contrast, or other critical display is approved by the code official.

2. For spaces in which lighting is specified to be installed in addition to the general lighting for the purpose of decorative appearance or for highlighting art or exhibits, provided that the additional lighting power shall be not more than 0.9 W/ft² (9.7 W/m²) in lobbies and not more than 0.75 W/ft² (8.1 W/m²) in other spaces.

Reason: All lighting controls requirements should be located in C405.2, and all lighting power requirements should be located in C405.3 and C405.4. We should not have lighting control requirements buried in exceptions within C405.3. This proposal consolidates all lighting control requirements in C405.2.

Furthermore, we need a clear definition of the term general lighting, which is currently used at least 14 times in Section C405, but nowhere else in the code. The term general lighting establishes many of the lighting controls requirements in the code, so it is important that we have a meaning for this term which is clear and concise in all instances.

The current definition of general lighting includes technical requirements, which should not be located in a definition (by editorial convention). This proposal would relocate those technical requirements to C405.1, so that they will be applicable throughout Section C405.

Do the proposed section references in C405.1 create a circular reference with C405.2.4? No! Consider one example - "task lighting for medical and dental purposes that is in addition to general lighting". There are two ways you could interpret this in a dental exam room:

First, if you wanted to try to game the code and call all lighting in a dental exam room "task lighting for dental purposes" then

1. This lighting cannot be exempt from your power calculations in C405.3.1 (because it is not separate from the
2. This lighting is not exempt from the controls requirements in C405.2.1 and C405.2.2 (because it is not separate from the general lighting).

However, if you claim only the dental exam light as "task lighting for dental purposes" then

1. The dental exam light is exempt from your lighting power calculations in C405.3 (because it is separate from the general lighting), and

2. The dental exam light is required to be on a separate manual switch (only) by C405.2.4, while the general lighting in the room is required to comply with the automatic control requirements in C405.2.1 and C405.2.2.

A detailed review of the other references to general lighting in C405.2.4 is just as solid (but too tedious to include here!)

The exceptions under C405.2.1 and C405.2.2 are provided for clarity. For example, if you consider "lighting for plant growth", this is specifically required in C405.2.4 to have a time-switch control which is independent of the other lighting controls in the space. But if this lighting were located in an open office area that was required to have occupant sensor control per C405.2.1, then we need to clarify that the occupant sensor required under C405.2.1 does not control the "lighting for plant growth" (because a plant's need for lighting is unrelated to human occupancy in the space).

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

Revisions for clarity
2018 International Energy Conservation Code

Revise as follows:

C405.2.1.2 Occupant sensor control function in warehouses: warehouse storage areas. Lighting in warehouse storage areas shall be controlled as follows:

1. Lighting in each aisleway shall be controlled independently of lighting in all other aisleways and open areas.
2. Occupant sensors shall automatically reduce lighting power within each controlled area to an unoccupied setpoint of not more than 50 percent of full power within 20 minutes after all occupants have left the controlled area.
3. Lights shall be turned off during scheduled unoccupied periods by: occupant sensors or by time-switch control complying with Section C405.2.2.1.
4. Occupant sensors shall be permitted to automatically turn on lighting upon occupancy within each controlled area. During the occupied schedule period or during times when the manual time switch override is enabled, the time switch control will enable lighting to be controlled by occupant sensors as described in Item 2.
5. Where lighting is also controlled by daylight responsive controls, the controls shall be configured so that the fraction of full power of the lighting shall not exceed the lesser of: the fraction of power allowed by this section and the fraction of power allowed by Section C405.2.3.1.

In warehouses, the lighting in aisleways and open areas shall be controlled with occupant sensors that automatically reduce lighting power by not less than 50 percent when the areas are unoccupied. The occupant sensors shall control lighting in each aisleway independently and shall not control lighting beyond the aisleway being controlled by the sensor.

Reason: This proposal increases savings. Prior to this change lights could be left on at 50% of power during scheduled unoccupied periods. However the least cost control, an occupancy sensor that turns lights off, does not increase the cost beyond the current code requirements.

There are a number of different alternatives that will also comply and provide partial lighting of unoccupied aisles during occupied hours.

- A partial off occupancy sensing system (dim all the lights or turn at least half the lights off when occupancy is sensed) in conjunction with a timeclock control that turns lights off after hours and reverts to the occupancy control in item 2 during occupied hours or when the timeclock override switch is enabled.
- An occupancy sensing system that receives a time signal and varies the unoccupied light output to partial off during the scheduled occupied period and to full off during the scheduled unoccupied period (unless it is over ridden).

Almost all warehouses will have daylit areas due to skylights being prescriptively required by Section C402.4.2 for enclosed spaces larger than 2,500 square feet directly under a roof and with a ceiling height greater than 15 feet. As a result it is desirable to be clear how the required occupancy sensors controls interact with daylight responsive controls. The daylight control requirements in Item 5 of Section C405.2.3.1, "shall be configured to completely shut off all controlled lights." With a 3% prescriptive skylight to floor ratio for half of the warehouse, these spaces will have enough daylight to turn off the lights around half the daylight hours of the year. This proposal specifies that when the two controls interact, the resulting power level is the lesser of the power levels...
specified for each control.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. If the occupancy sensing control is turning lights off then there is no cost increase.

If occupancy sensing is not full off then compliance with this proposal will have the relatively small cost of adding a timeclock control.

The rest of the requirements are clarification of how the controls are intended to perform and thus do not add cost.
CE165-19

IECC: C405.2.1.2

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1.2 Occupant sensor control function in warehouses warehouse storage areas. Lighting in warehouse storage areas shall be controlled as follows:

1. Lighting in each aisleway shall be controlled independently of lighting in all other aisleways and open areas.
2. Occupant sensors shall automatically reduce lighting power within each controlled area to an unoccupied setpoint of not more than 50 percent of full power within 20 minutes after all occupants have left the controlled area.
3. Lights which are not turned off by occupant sensors shall be turned off by time-switch control complying with Section C405.2.2.1.
4. Occupant sensors shall be permitted to automatically turn on lighting upon occupancy within each controlled area. Time-switch controls shall not turn lights on to greater than 50 percent of full power.

In warehouses, the lighting in aisleways and open areas shall be controlled with occupant sensors that automatically reduce lighting power by not less than 50 percent when the areas are unoccupied. The occupant sensors shall control lighting in each aisleway independently and shall not control lighting beyond the aisleway being controlled by the sensor.

Reason: There are some gaps in the current code. Specifically:

1. We should refer to “warehouse storage areas” as this is the relevant space type in Table C405.3.2(2), and this is the space type which is listed in C405.2.1 (the charging language).
2. Current code does not require that lights ever be turned completely off. This proposal would require shutoff by either occupant sensor or time-switch control.
3. Current code does not specify how long it takes for lighting to set back to 50 percent when aisles become unoccupied. This proposal specifies 20 minutes, which conforms to other requirements in the code.
4. Current code does not specify how lights should be turned on. This proposal specifies that automatic-on occupant sensors are permitted, but that time-switch controls (if provided) cannot turn lights on to more than 50%.

We are using the language “to an unoccupied setpoint of not more than 50 percent of full power” for consistency with a separate proposal for Section C405.2.3.1 which clarifies how daylight responsive controls will interact with the partial-off occupancy sensors described here.

There are a variety of ways that people may implement lighting controls to comply with this requirement. At the low end, automatic-on, automatic-off occupant sensors are the cheapest way to comply. These are allowed under current code, and will continue to be allowed if this proposal is approved. At the high end, a time-switch will be used to turn all lights in the warehouse on to 50% (or lower) at the beginning of a shift, and off at the end of a shift. During the shift, occupant sensors will switch the lights from 50% (or lower) when no activity is sensed to 100% when activity is sensed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
As outlined above, the least expensive option for complying with current code will continue to be allowed as a strategy to comply with code if this revision is approved.
CE166-19

IECC: C405.2.1.2

**Proponent:** Marilyn Williams, representing National Electrical Manufacturers Association

(mar_williams@nema.org)

**2018 International Energy Conservation Code**

Revise as follows:

**C405.2.1.2 Occupant sensor control function in warehouses. warehouses storage areas.** Lighting in warehouse storage areas shall be controlled as follows:

1. Lighting in each aisleway shall be controlled independently of lighting in all other aisleways and open areas.
2. **Occupant sensors shall** In warehouses, the lighting in aisleways and open areas shall be controlled with occupant sensors that automatically reduce lighting power within each controlled area by not less than 50 percent within 20 minutes after all occupants have left the controlled area, when the areas are unoccupied. The
3. **Lights which are not turned off by occupant sensors shall be turned off by time-switch control complying with Section C405.2.2.1, control lighting in each aisleway independently and shall not control lighting beyond the aisleway being controlled by the sensor.**
4. A manual control shall be provided to allow occupants to turn off lights in the space.

**Reason:** Revising this language will:

1. Reduce inconsistency and application confusion with warehouse lighting control
2. Reduce energy use (as written could increase energy through interpretation errors)
3. Increase code interpretation
4. Resolve compliance in application, approval and inspection
5. Will not change the intent or requirements of the code provision

The proposal is editorial, and intended to clarify correct application of occupancy sensors, and associated controls for warehouse storage areas. Warehouse spaces were added to the occupancy controls list of space types (C405.2.1) in the 2015 IECC update. Yet, warehouses were excluded from the specific requirements of the main occupancy sensor control functions. Because of this, and the unique control requirements, several elements of how occupancy sensors should operate in the warehouse environment are given no direction or completely left out of the section. This created the following compliance confusion that is resolved with this proposed revision.

1. How long should the area remain unoccupied before lighting would reduce by at least 50% lighting power?
2. How should lighting in warehouses ultimately be turned off?
3. Do manual control devices apply to warehouses or not?

Similar to the enumerated items put into the 2018 IECC version for open office plan spaces, this editorial
change provides clarity to how to apply lighting controls in warehouses storage area spaces. The proposed change clarifies control by item numbers as follows:

1. Item one simplifies language on control independent between aisleways and open areas.

2. Item two language aligns the time delay or "time out" for occupants leaving the warehouse area and turning off or reducing the lighting to 20 minutes. This aligns with the time delay for all other occupancy sensor spaces (C405.2.1.1), newer open plan office spaces (405.2.1.3) and maintains energy efficiency by reducing lighting power.

3. Item three revised language clarifies that the warehouse lighting automatically turns off according to methods already presented in the code (occupancy sensor or time-switch controls) but leaves the decision of automatic shut-off control method to the building design professional.

4. Item four clarifies control is available for the end user to turn lighting off.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Proposed language is a clarification and editorial in nature. There is no cost impact for implementation and increases energy efficiency through reducing confusion and increasing compliance.

Proposal # 4372

CE166-19
CE167-19

IECC: C405.2.1.1

**Proponent:** Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

**2018 International Energy Conservation Code**

Revise as follows:

**C405.2.1.1 Occupant sensor control function.** Occupant sensor controls in warehouses shall comply with Section C405.2.1.2. Occupant sensor controls in open plan office areas shall comply with Section C405.2.1.3. Occupant sensor controls for all other spaces specified in Section C405.2.1 shall comply with the following:

1. They shall automatically turn off lights within 20 minutes after all occupants have left the space.
2. They shall be manual on or controlled to automatically turn on the lighting to not more than 50-percent power.
3. They shall incorporate a manual control to allow occupants to turn off lights.

**Exception:** Full automatic-on controls with no manual control shall be permitted to control lighting in public corridors, interior parking areas, stairways, restrooms, primary building entrance areas, and lobbies, locker rooms, lobbies, library stacks, and areas where manual operation would endanger the safety or security of the room or building occupants. They shall incorporate a manual control to allow occupants to turn off lights, occupant safety or security.

**Reason:** The code currently requires that readily accessible manual controls be provided to allow occupants to turn the lights off in the space types listed in this exception. We don't believe this should be required by the code, because the occupant sensors will already turn the lights off when no occupants are present, meaning that the accessible manual control would only be used to turn off lights when occupants are present. This could compromise safety for building occupants in these types of spaces. We have changed the terminology “primary building entrance areas and lobbies” to read “lobbies” because we believe that all space types listed in this section of the code should be correlated with the space-by-space LPD table C405.3.2(2).

The safety and security language that is currently in this section of the code is a bit odd. The language proposed here, “areas where manual operation would endanger occupant safety or security” matches the language in C405.2.2 exception 2.

**Cost Impact:** The code change proposal will decrease the cost of construction. This proposal will reduce the cost of construction by eliminating the requirement for a manual control device in the indicated space types. We anticipate only a minimal impact on energy efficiency because we expect these manual controls are rarely used.

Proposal # 4837

IECC: C405.2.1, C405.2.1.1, C405.2.1.2

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association

(email: mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1 Occupant sensor controls. Occupant sensor controls shall be installed to control lights in the following space types complying with Sections C405.2.1.1, C405.2.1.2, and C405.2.1.3:

1. Classrooms/lecture/training rooms.
2. Conference/meeting/multipurpose rooms.
3. Copy/print rooms.
4. Lounges/breakrooms.
5. Enclosed offices.
6. Open-plan office areas.
7. Restrooms.
8. Storage rooms.
9. Locker rooms.
10. Other spaces 300 square feet (28 m²) or less that are enclosed by floor-to-ceiling height partitions.
11. Warehouse storage areas.

C405.2.1.1 Occupant sensor control function in automatic-full-off spaces. Occupant sensor controls in warehouses shall comply with Section C405.2.1.2. Occupant sensor controls in open plan office areas shall comply with Section C405.2.1.3. Occupant sensor controls for all other spaces specified in Section C405.2.1 shall comply with the following:

Lighting in these space types shall be controlled as follows:

Classrooms/lecture/training rooms.

Conference/meeting/multipurpose rooms.

Copy/print rooms.

Lounges/breakrooms.

Enclosed offices.

Restrooms.

Storage rooms 1000 square feet (90 m²) or less that are enclosed by floor-to-ceiling height partitions.

Locker rooms.

Other spaces 300 square feet (28 m²) or less that are enclosed by floor-to-ceiling height partitions.

1. They shall automatically turn off lights. Lighting shall automatically turn off within 20 minutes after
all occupants have left the space.

2. Lighting shall be manual on or controlled to automatically turn on the lighting to not more than 50-percent power.

   **Exception:** Full automatic-on controls shall be permitted to control lighting in public corridors, stairways, restrooms, primary building entrance areas and lobbies, and areas where manual-on operation would endanger the safety or security of the room or building occupants.

3. They shall incorporate a manual control **shall be provided** to allow occupants to turn off lights in the space.

C405.2.1.2 Occupant sensor control function in warehouses **automatic-partial-off spaces.** Lighting in these space types shall be controlled as follows:

**Warehouse storage areas.**

Storage rooms greater than 1000 square feet (90 m²) that are enclosed by floor-to-ceiling height partitions.

**Classroom labs.**

**Corridors.**

1. Lighting shall in warehouses, the lighting in aisleways and open areas shall be controlled with occupant sensors that automatically reduce lighting power **within each controlled area** by not less than 50 percent when the areas are unoccupied. The power shall be reduced within 20 minutes after all occupants have left the controlled area.

2. Lights which are not turned off by occupant sensors shall be turned off by time-switch control complying with Section C405.2.21.

3. A manual control **shall be provided** to allow occupants to turn off lights in the space.

4. In warehouse storage areas, lighting in each aisleway shall be controlled independently and shall not control lighting beyond the aisleway being controlled by the sensor. Lighting in all other aisleways and open areas.

   **Exception:** Spaces where the lighting power is 150 Watts or less.

**Reason:** Revising this language will:

1. Increase energy efficiency in buildings

2. Reduce inconsistency and application confusion with warehouse lighting control.

3. Increase code interpretation and usability

4. Resolve compliance in application, approval and inspection.

**see attachment for further information for reason**

**Cost Impact:** The code change proposal will increase the cost of construction. The cost impact for added controls only applies to storage rooms greater than 1000 square feet, library stacks, classroom labs, and corridors. There will be no cost impact to warehouse storage areas or other space types as the revision is an editorial clarification for those spaces.
CE169-19

IECC: C405.2.1, C405.2.1.1, C405.2.1.4(New)

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1 Occupant sensor controls. Occupant sensor controls shall be installed to control lights in the following space types:

1. Classrooms/lecture/training rooms.
2. Conference/meeting/multipurpose rooms.
3. Copy/print rooms.
4. Lounges/breakrooms.
5. Enclosed offices.
6. Open plan office areas.
7. Restrooms.
8. Storage rooms.
9. Locker rooms.
10. Corridors
11. Warehouse storage areas
12. Other spaces 300 square feet (28 m²) or less that are enclosed by floor-to-ceiling height partitions.

C405.2.1.1 Occupant sensor control function. Occupant sensor controls in warehouses shall comply with Section C405.2.1.2. Occupant sensor controls in open plan office areas shall comply with Section C405.2.1.3. Occupant sensor controls in corridors shall comply with Section C405.2.1.4. Occupant sensor controls for all other spaces specified in Section C405.2.1 shall comply with the following:

1. They shall automatically turn off lights within 20 minutes after all occupants have left the space.
2. They shall be manual on or controlled to automatically turn on the lighting to not more than 50-percent power.
   Exception: Full automatic-on controls shall be permitted to control lighting in public corridors, stairways, restrooms, primary building entrance areas and lobbies, and areas where manual-on operation would endanger the safety or security of the room or building occupants.
3. They shall incorporate a manual control to allow occupants to turn off lights.

Add new text as follows:

C405.2.1.4 Occupant sensor control function in corridors Occupant sensor controls in corridors shall uniformly reduce lighting power to not more than 50 percent of full power within 20 minutes after all occupants have left the space.

Exception: Corridors provided with less than two foot-candles of illumination on the floor at the darkest point with all lights on.
**Reason:** To save energy. Current code requires that occupant sensors be installed in any corridor which is smaller than 300 square feet (60 feet long for a 5 foot wide corridor). These will usually be automatic-on, automatic-off occupant sensors with manual override switch. C405.2 exception 2 exempts corridors which are exit passageways (see IBC) are exempt.

There should be one uniform requirement for occupant sensor control of lights in corridors regardless of whether they are smaller than 300 square feet, and we propose that this requirement should allow for lights to remain continuously “on” at a reduced level to alleviate safety concerns about people entering dark corridors before the lights will turn on.

By allowing corridor lighting to remain “on” at 50% when unoccupied, this proposal will also avoid most potential conflicts with the IBC, which requires that lighting in a corridor be maintained at a minimum of 1 foot-candle (at the darkest point) whenever spaces served by the corridor are occupied. An exception is also provided for corridors with less than 2 foot-candies of illumination at the darkest point when all lights are on, so that we are not requiring controls in darker corridors where there will be no opportunity for light reduction. The majority of corridors are lighted to >2 fc minimum, so occupancy sensors will still be widely required in corridors.

This proposal is technology-neutral, in that it requires a 50% reduction in lighting power, but does not specify whether this is achieved by switching alternate fixtures, or by uniformly dimming all fixtures.

**Cost Impact:** The code change proposal will increase the cost of construction

Construction costs will be increased in projects which are required to add occupant sensors (i.e. those with corridors greater than 300 sf).

At 0.66 watts/sf (see C405.3.2(2)) a >300 sf corridor will have >200 watts of lighting installed. A 50% reduction would be >100 watt when lights are set back. Assuming 20 hours/day of light reduction (corridors are infrequently occupied), this yields a savings of at least 730 kwh/year ($77.82 per year at the national average rate of $0.1066/kwh).

See https://www.eia.gov/electricity/annual/html/epa/_02_07.html for national average cost of electricity.

A 60 foot corridor can be controlled from one $80 occupant sensor. Even with installation and wiring costs added in, this will have an attractive payback.

Proposal # 4776

CE169-19
CE170-19

IECC: C405.2.1.3, C405.2.3.1

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1.3 Occupant sensor control function in open plan office areas. Occupant sensor controls in open plan office spaces less than 300 square feet (28 m²) in area shall comply with Section C405.2.1.1. Occupant sensor controls in all other open plan office spaces shall comply with all of the following:

1. The controls shall be configured so that general lighting can be controlled separately in control zones with floor areas not greater than 600 square feet (55 m²) within the open plan office space.
2. The controls shall automatically turn off general lighting in all control zones within 20 minutes after all occupants have left the open plan office space.
3. The controls shall be configured so that general lighting power in each control zone is reduced by not less than 80 percent of the full zone general lighting power in a reasonably uniform illumination pattern within 20 minutes of all occupants leaving that control zone. Control functions that switch control zone lights completely off when the zone is vacant meet this requirement.
4. The controls shall be configured such that any daylight responsive control will activate open plan office space general lighting or control zone general lighting only when occupancy for the same area is detected.

C405.2.3.1 Daylight-responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit zones in accordance with Section C405.2.3.2.
2. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.
3. Calibration mechanisms shall be in a location with ready access.
4. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light output or lower.
5. Daylight responsive controls shall be configured to completely shut off all controlled lights.
6. When occupant sensor controls have reduced the lighting power to an unoccupied setpoint in accordance with Sections C405.2.1.2 through C405.2.1.4, daylight responsive controls shall continue to adjust electric light levels in response to available daylight, but shall be configured to not increase the lighting power above the specified unoccupied setpoint.
7. Lights in sidelit zones in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

Exception: Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

Reason: The code allows “partial-off” occupant sensors in warehouses and open office areas. A separate
Proposal being heard in this cycle would also require that partial-off occupant sensors be provided in corridors (although few corridors have >150W of lighting within a daylight zone).

For lights which will be controlled by both partial-off occupant sensors and daylight responsive controls, it is important that both controls work together to achieve maximum energy savings. Specifically that:

1. Daylight responsive controls continue to reduce light levels in response to daylight in spaces which are unoccupied.
2. Daylight responsive controls do not increase light levels above the unoccupied setpoint (either 50% or 20% depending on the space type) in spaces which are unoccupied.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Since “partial-off” occupant sensors are not required for warehouses and open office areas (auto-off is the cheaper way to comply with code), there is no added cost or complexity here for the code-minimum controls solution.

Proposal # 4989

CE170-19
CE171-19

IECC: C405.2.1.3

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1.3 Occupant sensor control function in open plan office areas. Occupant sensor controls in open plan office spaces less than 300 square feet (28 m²) in area shall comply with Section C405.2.1.1. Occupant sensor controls in all other open plan office spaces shall comply with all of the following:

1. The controls shall be configured so that general lighting can be controlled separately in control zones with floor areas not greater than 600 square feet (55 m²) within the open plan office space.

2. General lighting in each control zone shall be permitted to automatically turn on upon occupancy within the control zone. General lighting in other unoccupied zones within the open plan office space shall be permitted to turn on to no more than 20 percent of full power or remain unaffected.

2-3. The controls shall automatically turn off general lighting in all control zones within 20 minutes after all occupants have left the open plan office space.

3. The controls shall be configured so that general lighting power.

4. General lighting in each control zone is reduced by not less than 80 percent of the full zone general lighting power to a reasonably uniform illumination pattern within 20 minutes of all occupants leaving that control zone. Control functions that switch control zone lights completely off when the zone is vacant meet this requirement. The controls shall uniformly reduce lighting power to an unoccupied setpoint of not more than 20 percent of full power within 20 minutes after all occupants have left the control zone.

4-5. The controls shall be configured such that any daylight responsive control will activate open plan office space general lighting or control zone general lighting only when occupancy for the same area is detected.

Reason: The code is silent about how lights are to be turned on in open office areas. Since the “on” function in occupant sensors is something that we are usually quite concerned with in the code, this silence is unusual, and users of the code will make their own (different) assumptions about how to interpret this silence. The addition of new item 2 above clarifies this. Revision of item 4 is editorial in nature, and intended to conform the language in this section more closely with other code provisions related to occupant sensors. The language “to an unoccupied setpoint of not more than 20 percent of full power” is for consistency with a separate proposal for Section C405.2.3.1 which clarifies how daylight responsive controls will interact with the partial-off occupancy sensors described here. Regardless of whether that separate proposal is approved, this language still makes sense and describes the intended result.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. These changes reduce the potential for confusion and inconsistency in application of the code.

Proposal # 4774

CE171-19
Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1.3 Occupant sensor control function in open plan office areas. Occupant sensor controls in open plan office spaces less than 300 square feet (28 m²) in area shall comply with Section C405.2.1.1. Occupant sensor controls in all other open plan office spaces shall comply with all of the following:

1. The controls shall be configured so that general lighting can be controlled separately in control zones with floor areas not greater than 600 square feet (55 m²) within the open plan office space. 
   Exception: Where general lighting is turned off by time-switch control complying with Section C405.2.2.1

2. The controls shall automatically turn off general lighting in all control zones within 20 minutes after all occupants have left the open plan office space.

3. The controls shall be configured so that general lighting power in each control zone is reduced by not less than 80 percent of the full zone general lighting power in a reasonably uniform illumination pattern within 20 minutes of all occupants leaving that control zone. Control functions that switch control zone lights completely off when the zone is vacant meet this requirement.

4. The controls shall be configured such that any daylight responsive control will activate open plan office space general lighting or control zone general lighting only when occupancy for the same area is detected.

Reason: Private offices are often configured so that occupants need to pass through open office areas to get to restrooms, printers, pantries, etc. and to exit the building. When an occupant in a private office works later than the last occupant of the open office space, they will find the lights have been set back or turned off by the occupant sensors in the open office area that they need to pass through. This is not necessarily a safety or security issue, because there will likely be some night lighting, and lights can be turned on for safe passage through the space, but it does create a perception issue. If you are the person working in the private office when the rest of the lights shut off, you may feel like (a) it is unsafe to remain, or (b) you have worked too late and it is time to go home. Some organizations won’t like this. The reason why the code currently allows lights in unoccupied areas of an open office to remain on at a reduced level is to that the last person working late in the open office area does not feel like they are all alone in a pool of light in the middle of a dark room. The proposed change would apply the same reasoning for the last person working late in a private office. The situation is very similar, and especially if the private office has a glass office front.

It is possible to achieve this same result with networked lighting controls that tie private office occupant sensors together with open office occupant sensors, but this is quite expensive. Achieving this with time scheduling results in reduced energy savings, but also reduced first cost and less controls complexity

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This exception allows more flexibility, but does not alter the lowest-cost path of compliance (which remains automatic-on, automatic-off occupant sensors).
CE173-19

IECC: C405.2.1.3

Proponent: Jonathan McHugh, representing McHugh Energy Consultants Inc. (jon@mchughenergy.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.1.3 Occupant sensor control function in open plan office areas. Occupant sensor controls in open plan office spaces less than 300 square feet (28 m²) in area shall comply with Section C405.2.1.1. Occupant sensor controls in all other open plan office spaces shall comply with all of the following:

1. The controls shall be configured so that general lighting can be controlled separately in control zones with floor areas not greater than 600 square feet (55 m²) within the open plan office space.

2. General lighting in each control zone shall be allowed to automatically turn on upon occupancy within the control zone. General lighting in other unoccupied zones within the open plan office space shall be allowed to turn on to no more than 20 percent of full power or remain unaffected. Controls shall automatically return lighting to their previous settings if occupancy is detected within 30 seconds of lights being turned off.

3. The controls shall automatically turn off general lighting in all control zones within 20 minutes after all occupants have left the open plan office space. Controls shall automatically return lighting to their previous settings if occupancy is detected within 30 seconds of lights being turned off.

4. General lighting in each control zone shall turn off or uniformly reduce lighting power to no more than 20 percent of full power within 20 minutes after all occupants have left the control zone. Control functions that switch control zone lights completely off when the zone is vacant meet this requirement.

5. The general lighting also served by daylight responsive controls as required by Section C405.2.3, the occupant sensor control and the daylight responsive controls shall be configured such that any daylight responsive control will activate open plan office space general lighting or control zone general lighting only when occupancy for the same area is detected, so that power does not exceed the lesser of: the allowed power in Section C405.2.3.1 and the allowed power in Items 2 through 4 of this section.

Reason:

Item 2 clarifies what happen when occupancy is detected. Revision of item 3 addresses the concern that lights are turned completely off and manual-on sensors are used, this could be a safety issue as the last occupant either walks through a dark open office area or must find switches to turn the lights on. This proposal will address this safety issue with the specification that manual on control function is overridden to automatic on if the motion is sensed within 30 seconds of lights being turned off. This capability can be accomplished with networked controls and also simpler controls.

Item 5 clarifies that luminaires controlled by both occupancy sensors and daylight responsive controls are controlled to the lower power level of the two controls.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal has not effect on cost. This proposal clarifies the existing language.
Proponent: Marilyn Williams, representing National Electrical Manufacturers Association

(Proponent contact information)

**2018 International Energy Conservation Code**

Revise as follows:

**C405.2 Lighting controls (Mandatory).** Lighting systems shall be provided with controls that comply with one of the following:

1. Lighting controls as specified in Sections C405.2.1 through C405.2.6.
2. Luminaire level lighting controls (LLLC) and lighting controls as specified in Sections C405.2.1, C405.2.4, C405.2.3, C405.2.5, and C405.2.6. The LLLC luminaire shall be independently capable of:
   1. Monitoring occupant activity to brighten or dim lighting when occupied or unoccupied, respectively.
   2. Monitoring ambient light, both electric light and daylight, and brighten or dim artificial light to maintain desired light level.
   3. For each control strategy, configuration and reconfiguration of performance parameters including; bright and dim setpoints, timeouts, dimming fade rates, sensor sensitivity adjustments, and wireless zoning configurations.

**Exceptions:** Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted.
2. Interior exit stairways, interior exit ramps and exit passageways.
3. Emergency egress lighting that is normally off.

**C405.2.2 Time-switch controls.** Each area of the building that is not provided with **occupant sensor controls** complying with Section C405.2.1.1 shall be provided with **time-switch controls** complying with Section C405.2.2.1.

**Exception:** Where a **manual control** provides light reduction in accordance with Section C405.2.2.2, **time-switch controls** shall not be required for the following:

1. Spaces where patient care is directly provided.
2. Spaces where an automatic shutoff would endanger occupant safety or security.
3. Lighting intended for continuous operation.
4. Shop and laboratory classrooms.

**C405.2.2.1 Time-switch control function.** Each space provided with **time-switch controls** shall be provided with a **manual control** for light reduction in accordance with Section C405.2.2.2. **Time-switch controls** shall include an override switching device that complies with the following:

1. Have a minimum 7-day clock.
2. Be capable of being set for seven different day types per week.
3. Incorporate an automatic holiday “shutoff” feature, which turns off all controlled lighting loads for
not fewer than 24 hours and then resumes normally scheduled operations.

4. Have program backup capabilities, which prevent the loss of program and time settings for not fewer than 10 hours, if power is interrupted.

5. Include an override switch that complies with the following:

   5.1. The override switch shall be a manual control.
   5.2. The override switch, when initiated, shall permit the controlled lighting to remain on for not more than 2 hours.
   5.3. Any individual override switch shall control the lighting for an area not larger than 5,000 square feet (465 m²).

Exceptions:

1. Within mall concourses, auditoriums, sales areas, manufacturing facilities and sports arenas:

   1.1. The time limit shall be permitted to be greater than 2 hours, provided that the switch is a captive key device.
   1.2. The area controlled by the override switch shall not be limited to 5,000 square feet (465 m²) provided that such area is less than 20,000 square feet (1860 m²).

2. Where provided with manual control, the following areas are not required to have light reduction control:

   2.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   2.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
   2.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

\textbf{C405.2.2.2 Light-reduction controls.} Spaces required to have light reduction controls shall have a manual control that allows the occupant to reduce the connected lighting load in a reasonably uniform illumination pattern by not less than 50 percent. Lighting reduction shall be achieved by one of the following or another approved method:

   1. Controlling all lamps or luminaires.
   2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
   3. Switching the middle lamp luminaires independently of the outer lamps.
   4. Switching each luminaire or each lamp.

   \textbf{Exception:} Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

\textbf{C405.2.3 Daylight-responsive controls.} Daylight-responsive Each area of the building shall have light reduction controls complying with Section C405.2.3.1 shall be provided to control the electric lights within daylight zones in the following spaces.

\textbf{Exceptions:} Where provided with manual control, the following areas are not required to have light reduction control:

1. Spaces that have only one luminaire with a total rated power of less than 100 watts.
2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
3. Corridors, lobbies, electrical rooms and or mechanical rooms.
4. Daylight zones with daylight responsive controls complying with Section C405.2.4 more than 150 watts of general lighting within sidelit zones complying with Section C405.2.3.2 General
lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4. 2. Spaces with a total of more than 150 watts of general lighting within toplit zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance \( LPA_{adj} \) calculated in accordance with Equation 4-9

\[
LPA_{adj} = \frac{LPA_{norm} \times (1.0 - 0.4 \times UDZFA / TBFA)}{}
\]

(Equation 4-9)

where:

\( LPA_{adj} \) = Adjusted building interior lighting power allowance in watts.

\( LPA_{norm} \) = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.

\( UDZFA \) = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.

\( TBFA \) = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

C405.2.3.1 Daylight-responsive Light-reduction control function. Light-reduction controls shall have a manual control that allows the occupant to turn the lights completely off, and to an intermediate step that reduces the connected lighting load by not less than 50 percent. Lighting reduction shall be achieved by one of the following or another approved method:

1. Controlling all lamps or luminaires.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
3. Switching the middle lamp luminaires independently of the outer lamps.
4. Switching each luminaire or each lamp.

Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit zones in accordance with Section C405.2.3.2.
2. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.
3. Calibration mechanisms shall be in a location with ready access.
4. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light.
output or lower.

5. *Daylight responsive controls* shall be configured to completely shut off all controlled lights.

6. Lights in *sidelit zones* in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

**Exception:** Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

**Reason:** Revising this language will:

1. Reduce inconsistency and confusion with light-reduction control requirements

2. Reduce energy use

3. Increase code interpretation simplicity

4. Resolve compliance in application, approval and inspection

5. Improve the occupant's ability to operate their lighting

6. Will not change the intent or requirements of the code provision.

Beginning with the 2015 IECC, light reduction controls has been a significant area of confusion in the lighting control section. Much of this is founded in the editing from the 2012 IECC to the 2015 IECC. As an example, some of the exceptions to light reduction control are found in the C405.2.2.1 Time-switch control function section. This proposed change puts these exceptions under the light reduction control section, instead of the Time-switch control function section. This will simplify reading and interpretation of the code, as one would not expect to find code provision exceptions residing in a different section.

The proposal simplifies code language by eliminating confusing and redundant pre-condition phrases in the exceptions to C405.2.2 Time-switch control, and C405.2.2.1 Time-switch control function, by removing “in accordance with Section C405.2.2.2 Light reduction control”.

Removing the light reduction control from being a subsection of C405.2.2 Time-switch controls, into its own section C405.2.3, as was done with the C405.2.5 Manual Controls section in the 2018 IECC cycle, will help clarify ambiguity within the electrical and lighting design community. Some interpret that the light reduction control requirements only apply to spaces where the lighting shut-off is accomplished through time-switch control. Some jurisdictions, like the City of Houston, have written clarifying position statements to overcome the confusion with how this code section is written. The verbal interpretation given by the ICC technical support line has supported the interpretation that light reduction control applies to all spaces, regardless of lighting shut-off method, and regardless of its sub-paragraphing under the time-switch control provision.

The proposal applies light reduction control for good occupant controllability of lighting in the space and for increased energy efficiency to all buildings spaces not listed in the exceptions.
This would align the IECC with other energy efficiency codes and reduce the significant application and inspection confusion that currently exists with how this provision is written.

**Cost Impact:** The code change proposal will increase the cost of construction
Baselining the cost of construction at where light reduction control is applicable to all spaces, except spaces where exempt, the cost remains the same as current code and the energy efficiency benefits remain the same.

Proposal # 4382

---

2018 International Energy Conservation Code

Revise as follows:

C405.2 Lighting controls (Mandatory). Lighting systems shall be provided with controls that comply with one of the following.

1. Lighting controls as specified in Sections C405.2.1 through C405.2.6.
2. Luminaire level lighting controls (LLLC) and lighting controls as specified in Sections C405.2.1, C405.2.4, C405.2.5, and C405.2.6. The LLLC luminaire shall be independently capable of:
   2.1. Monitoring occupant activity to brighten or dim lighting when occupied or unoccupied, respectively.
   2.2. Monitoring ambient light, both electric light and daylight, and brighten or dim artificial light to maintain desired light level.
   2.3. For each control strategy, configuration and reconfiguration of performance parameters including; bright and dim setpoints, timeouts, dimming fade rates, sensor sensitivity adjustments, and wireless zoning configurations.

Exceptions: Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted.
2. Interior exit stairways, interior exit ramps and exit passageways.
3. Emergency egress lighting that is normally off.

C405.2.2 Time-switch controls. Each area of the building that is not provided with occupant sensor controls complying with Section C405.2.1.1 shall be provided with time-switch controls complying with Section C405.2.2.1.

Exception Exceptions: Where a manual control provides light reduction in accordance with Section C405.2.2.2, time-switch controls shall not be required for the following:

1. Spaces where patient care is directly provided.
2. Spaces where an automatic shutoff would endanger occupant safety or security.
3. Lighting intended for continuous operation.
4. Shop and laboratory classrooms.

C405.2.2.1 Time-switch control function. Each space provided with time-switch controls shall be provided with a manual control for light reduction in accordance with Section C405.2.2.2. Time-switch controls shall include an override switching device that complies with comply with the all of the following:

1. Automatically turn lights off when the space is scheduled to be unoccupied.
2. Have a minimum 7-day clock.
3. Be capable of being set for seven different day types per week.
4. Incorporate an automatic holiday “shutoff” feature, which turns off all controlled lighting loads for not fewer than 24 hours and then resumes normally scheduled operations.
5. Have program backup capabilities, which prevent the loss of program and time settings for not fewer than 10 hours, if power is interrupted.
6. Include an override switch that complies with the following:

   6.1. The override switch shall be a manual control.
   6.2. The override switch, when initiated, shall permit the controlled lighting to remain on for not more than 2 hours.
   6.3. Any individual override switch shall control the lighting for an area not larger than 5,000 square feet (465 m²).

**Exception**: Within mall concourses, auditoriums, sales areas, manufacturing facilities and sports arenas:

   1.1. The time limit shall be permitted to be greater than 2 hours, provided that the switch is a captive key device.
   1.2. The area controlled by the override switch shall not be limited to 5,000 square feet (465 m²) provided that such area is less than 20,000 square feet (1860 m²).

2. Where provided with manual control, the following areas are not required to have light reduction control:

   2.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   2.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
   2.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

*C405.2.2* C405.2.3.1 Light-reduction controls. **Control function.** Spaces required to have light-reduction controls shall have a manual control that allows the occupant to reduce the connected lighting load in a reasonably uniform illumination pattern by not less than 50 percent. Lighting reduction shall be achieved by one of the following or another approved method:

1. Controlling all lamps or luminaires.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
3. Switching the middle lamp luminaires independently of the outer lamps.
4. Switching each luminaire or each lamp.

**Exception**: Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

**Add new text as follows:**

*C405.2.3* Light reduction controls Where not provided with occupant sensor controls complying with Section C405.2.1.1, *general lighting* shall be provided with light reduction controls complying with C405.2.3.1.

**Exceptions:**

1. Luminaires controlled by daylight responsive controls complying with C405.2.4.
2. Luminaires controlled by special application controls complying with C405.2.5.

3. Where provided with manual control, the following areas are not required to have light reduction control:

   3.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   3.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
   3.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

Revise as follows:

**C405.2.4 C405.2.5 Specific application controls.** Specific application controls shall be provided for the following:

1. The following lighting shall be controlled by an occupant sensor complying with Section C405.2.1.1 or a time-switch control complying with Section C405.2.2.1. In addition, a manual control shall be provided to control such lighting separately from the general lighting in the space:
   1.1. Display and accent.
   1.2. Lighting in display cases.
   1.3. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting.
   1.4. Lighting equipment that is for sale or demonstration in lighting education.

2. *Sleeping units* shall have control devices or systems that are configured to automatically switch off all permanently installed luminaires and switched receptacles within 20 minutes after all occupants have left the unit.

**Exceptions:**

1. Lighting and switched receptacles controlled by card key controls.
2. Spaces where patient care is directly provided.

3. Permanently installed luminaires within *dwelling units* shall be provided with controls complying with Section C405.2.1.1 or C405.2.2.2. C405.2.3.1.

4. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a time switch control complying with Section C405.2.2.1 that is independent of the controls for other lighting within the room or space.

**C405.2.3 C405.2.4 Daylight-responsive controls.** *Daylight-responsive controls* complying with Section C405.2.3.1 shall be provided to control the electric lights within *daylight zones* in the following spaces:

1. Spaces with a total of more than 150 watts of general lighting within sidelit zones complying with Section C405.2.3.2. *General lighting* does not include lighting that is required to have specific application control in accordance with Section C405.2.4.

2. Spaces with a total of more than 150 watts of general lighting within toplit zones complying with Section C405.2.3.3.

**Exceptions:** Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance \( (LPA_{adj}) \) calculated in accordance with Equation 4-9

\[
LPA_{adj} = \frac{LPA_{norm} \times (1.0 - 0.4 \times UDZFA / TBFA)}{TBFA}
\]

(Equation 4-9)

where:

\( LPA_{adj} = \text{Adjusted building interior lighting power allowance in watts.} \)

\( LPA_{norm} = \text{Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.} \)

\( UDZFA = \text{Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.} \)

\( TBFA = \text{Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.} \)

**Reason:** The existing Section C405.2.2 is not straightforward. One of the biggest reasons is that it includes scoping and technical requirements for two different energy savings strategies: switching lights off by time scheduling, and light reduction controls to allow occupants to operate lights at a lower level. The applicability of the requirements for these two strategies is similar, but not identical, resulting in a lot of complicated exceptions. This proposal would untangle these requirements by putting the light reduction controls in a new section C405.2.3. This will dramatically improve the reading of Section C405.2.2 and eliminate several instances where we establish a new control requirement through an exception.

The deletion of exceptions language under C405.2.2 appears to remove the requirement for light reduction controls from the four listed applications, but this requirement is actually maintained (since these applications are not provided with occupant sensor controls, they would still be required to have light reduction controls).

This proposal does not change the applicability or stringency of controls requirements. It is a purely editorial change which makes the code easier to use and enforce.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This proposal does not change the applicability or stringency of controls requirements. It is a purely editorial change which makes the code easier to use and enforce.

2018 International Energy Conservation Code

Revise as follows:

C405.2 Lighting controls (Mandatory). Lighting systems shall be provided with controls that comply with one of the following.

1. Lighting controls as specified in Sections C405.2.1 through C405.2.6.
2. Luminaire level lighting controls (LLLC) and lighting controls as specified in Sections C405.2.1, C405.2.4 and C405.2.5. The LLLC luminaire shall be independently capable of:
   2.1. Monitoring occupant activity to brighten or dim lighting when occupied or unoccupied, respectively.
   2.2. Monitoring ambient light, both electric light and daylight, and brighten or dim artificial light to maintain desired light level.
   2.3. For each control strategy, configuration and reconfiguration of performance parameters including; bright and dim setpoints, timeouts, dimming fade rates, sensor sensitivity adjustments, and wireless zoning configurations.

Exceptions: Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted.
2. Spaces where an automatic shutoff would endanger occupant safety or security.
3. Interior exit stairways, interior exit ramps and exit passageways.
4. Emergency egress lighting that is normally off.

C405.2.2 Time-switch controls. Each area of the building that is not provided with occupant sensor controls complying with Section C405.2.1.1 shall be provided with time-switch controls complying with Section C405.2.2.1.

Exception: Where a manual control provides light reduction in accordance with Section C405.2.2.2, time-switch controls shall not be required for the following:

1. Spaces where patient care is directly provided.
2. Spaces where an automatic shutoff would endanger occupant safety or security.
3. Lighting intended for continuous operation.
4. Shop and laboratory classrooms.

Reason: The “safety” exception in C405.2 is quite important. If written too narrowly, it can compromise safety. But if written too broadly, it can become a loophole that creates unnecessary exceptions from the lighting controls requirements in the code. Let’s examine the current language.

Areas “designated as security or emergency areas”. Designated by whom? Such designations are shown on floor plans? Is this meant to be limited to 911 call centers and prisons? Or is this meant to include bank branches and fire stations? Refuge areas? Muster points?
“That are required to be continuously lighted”. Required by whom? What jurisdiction requires that lights operate continuously in buildings which are unoccupied? Jurisdictional *lighting* requirements are common – for bank ATM areas, hospitals, swimming pools, kitchens, parking lots, etc. as well as for egress lighting required by IBC. But these requirement are almost always limited in duration – either while the space or building is occupied, while a certain activity is occurring, or after dark for exterior areas. There is almost never a requirement that lights operate continuously. So if this “requirement” that the space be continuously lighted does not come from the jurisdiction, does it come from the building owner?

It is also possible that the current exception does not cover all spaces where lighting controls could endanger occupants. For example, dangerous work is performed in some (but not all) laboratories and workshops.

The proposed language, “Spaces where an automatic shutoff would endanger occupant safety or security” is already an exception from the time-switch controls requirements in section C405.2.2, and it makes sense to apply this language more broadly as the exception from occupant sensor and daylight responsive controls requirements as well.

An “automatic shutoff” could be planned or unplanned, and could be the result of a malfunctioning control system (e.g. occupant sensors shut off lights in an occupied space).

“Would” endanger is strong language. There is no guarantee that any shutoff would endanger occupants, but this is better than the permissive language alternates "could", "may" etc.

And finally, it is the “occupants” who would need to be endangered. We are not using this as an excuse to leave lights burning continuously for “security” lighting to secure an empty room. In the 21st century we have better ways to secure spaces than leaving the lights on all the time and having a guard walk by occasionally to look in.

Once we have made this change in C405.2 then we can eliminate some additional exceptions in C405.2.2.

- “Lighting intended for continuous operation” has always been problematic. “Intended” by whom? Since it is quite rare for an authority to have such a requirement, this is usually interpreted to mean that a building owner “requires” (i.e. “wants”) the lighting to be operated continuously. If an authority has such a requirement, then that requirement would supercede this code (per C101.3). But even if this is an owner “requirement” at the time the space is built, requirements change over time. A store which is intended to be 24-hour operation may well change to 18-hour operation during an economic downturn, or close and be re-opened by someone else who runs a 12-hour operation.
- “Shop and laboratory classrooms” – if there is a safety concern then the proposed Exception 1 to C405.2 would provide an exemption. It should be noted, however, that in practice many spaces of this type are currently provided with occupant sensors.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The intent of this proposal is to make existing exceptions clearer and more enforceable, not to change the scope of these exceptions.

Proposal # 4778

CE176-19
Proponent: Glenn Heinmiller, Lam Partners, representing Self (glenn@lampartners.com); Jack Bailey (jbailey@oneluxstudio.com)

2018 International Energy Conservation Code
Revise as follows:

C405.2.2.1 Time-switch control function. Each space provided with time-switch controls shall be provided with a manual control for light reduction control in accordance with Section C405.2.2.2. Time-switch controls shall include an override switching device that complies with the following:

1. Have a minimum 7-day clock.
2. Be capable of being set for seven different day types per week.
3. Incorporate an automatic holiday “shutoff” feature, which turns off all controlled lighting loads for not fewer than 24 hours and then resumes normally scheduled operations.
4. Have program backup capabilities, which prevent the loss of program and time settings for not fewer than 10 hours, if power is interrupted.
5. Include an override switch that complies with the following:
   5.1. The override switch shall be a manual control.
   5.2. The override switch, when initiated, shall permit the controlled lighting to remain on for not more than 2 hours.
   5.3. Any individual override switch shall control the lighting for an area not larger than 5,000 square feet (465 m²).

Exceptions:

1. Within mall concourses, auditoriums, sales areas, manufacturing facilities and sports arenas:
   1.1. The time limit shall be permitted to be greater than 2 hours, provided that the switch is a captive key device.
   1.2. The area controlled by the override switch shall not be limited to 5,000 square feet (465 m²) provided that such area is less than 20,000 square feet (1860 m²).
2. Where provided with manual control, the following areas are not required to have light reduction control:
   2.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   2.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
   2.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

Reason: This proposal clarifies of the intent of the code by replacing a confusing phrase with the correct term. The phrase “manual control for lighting reduction” is confusing. It should be replaced with “light-reduction control” which is what this paragraph is referring to. Light-reduction controls are described in C405.2.2.2

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is only a clarification.

Proposal # 4665
CE178-19
IECC: C405.2.2.1

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association
(mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C405.2.2.1 Time-switch control function. Each space provided with time-switch controls shall be provided with a manual control for light reduction in accordance with Section C405.2.2.2. Time-switch controls shall include an override switching device that complies with the following:

1. Have a minimum 7-day clock.
2. Be capable of being set for seven different day types per week.
3. Incorporate an automatic holiday “shutoff” feature, which turns off all controlled lighting loads for not fewer than 24 hours and then resumes normally scheduled operations.
4. Have program backup capabilities, which prevent the loss of program and time settings for not fewer than 10 hours, if power is interrupted.
5. Include an override switch that complies with the following:
   5.1. The override switch shall be a manual control.
   5.2. The override switch, when initiated, shall permit the controlled lighting to remain on for not more than 2 hours.
   5.3. Any individual override switch shall control the lighting for an area not larger than 5,000 square feet (465 m²).

Exceptions:

1. Within mall concourses, auditoriums, sales areas, manufacturing facilities and sports arenas:
   1.1. The time limit shall be permitted to be greater than 2 hours, provided that the switch is a captive key device.
   1.2. The area controlled by the override switch shall not be limited to 5,000 square feet (465 m²) provided that such area is less than 20,000 square feet (1860 m²).
2. Where provided with manual control, the following areas are not required to have light reduction control:
   2.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   2.2. Spaces that use less than 0.60.45 watts per square foot (6.5–4.9 W/m²).
   2.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

Reason: Revising this language will:
1. Update the code for use of LED lighting
2. Reduce energy use

As lighting has become more efficient with the use of LEDs, the lighting power density and wattage of luminaires has reduced significantly. However, the Light Reduction Control exception found under C405.2.2.1, has not adjusted accordingly. Both the one luminaire wattage exception (2.1) and the space lighting power density exception (2.2), are the same values as published under the 2009 IECC version. These values use a florescent lighting power baseline that is not consistent with either current lighting allowances used in the code.
today, nor with the solid state technology that is now the building standard.

The wattage exception for a single luminaire is adjusted to 60 watts, well above the wattage of a standard single 2x4 LED fixture found on the market today. The lighting power exception has been adjusted down by 25% to 0.45 watts per square foot. This aligns with the reduction changes in lighting power density allowance from the 2009 IECC to the proposed values from ASHRAE 90.1-2019.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost impact. This editorial change clarifies the code intent and will improve compliance and consistency for energy efficient control of lighting.

Proposal # 4386

CE178-19
CE179-19

IECC: C405.2.2.2

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, representing International Association of Lighting Designers (glenn@lamppartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.2.2 Light-reduction controls. Spaces required to have light-reduction controls shall have manual controls that allow the occupant to turn the lights off, and reduce the connected lighting load in a reasonably uniform illumination pattern by not less than 50 percent. Lighting reduction shall be achieved by using one of the following or another approved method:

1. Controlling all lamps or luminaires. Continuous dimming of all luminaires from full output to less than 20 percent of full power.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps. Switching all luminaires to a reduced output of not less than 30 percent, and not more than 70 percent of full power.
3. Switching the middle lamp luminaires independently of the outer lamps. Switching alternate luminaires or alternate rows of luminaires to achieve a reduced output of not less than 30 percent, and not more than 70 percent of full power.
4. Switching each luminaire or each lamp.

Exception: Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

Reason: The existing code language referring to switching of "lamps" is outdated. Modern LED luminaires no longer have lamps and are not referred to in this way. When the 2021 IECC is adopted in 2022 and 2023 this terminology will seem archaic. The proposed language is technology neutral, in that it describes a result which can be achieved using either LED or obsolete lighting technologies like fluorescent. This proposal also incorporates the word "dimming" to clarify that dimming is an acceptable strategy for "light reduction controls". While dimming is permitted by #1 in the existing code, a surprisingly large number of code users do not understand this because the word "dimming" is not specifically used.

Finally, this proposal fixes a problem with the existing language. As currently written, there is not actually a requirement for an intermediate step between "on" and "off" because "off" is "a reduction of not less than 50 percent". This proposal specifically requires that an intermediate step be provided between "on" and "off".

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is editorial.

Proposal # 4781
CE180-19

IECC: C405.2.2.1

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, representing Self (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.2.1 Time-switch control function. Each space provided with time-switch controls shall be provided with a manual control for light reduction in accordance with Section C405.2.2.2. Time-switch controls shall include an override switching device that complies with all of the following:

1. Automatically turn off the lights when the space is scheduled to be unoccupied.
2. Have a minimum 7-day clock.
3. Be capable of being set for seven different day types per week.
4. Incorporate an automatic holiday “shutoff” feature, which turns off all controlled lighting loads for not fewer than 24 hours and then resumes normally scheduled operations.
5. Have program backup capabilities, which prevent the loss of program and time settings for not fewer than 10 hours, if power is interrupted.
6. Include an override switch that complies with the following:
   6.1. The override switch shall be a manual control.
   6.2. The override switch, when initiated, shall permit the controlled lighting to remain on for not more than 2 hours.
   6.3. Any individual override switch shall control the lighting for an area not larger than 5,000 square feet (465 m²).

Exceptions:

1. Within mall concourses, auditoriums, sales areas, manufacturing facilities and sports arenas:
   1.1. The time limit shall be permitted to be greater than 2 hours, provided that the switch is a captive key device.
   1.2. The area controlled by the override switch shall not be limited to 5,000 square feet (465 m²) provided that such area is less than 20,000 square feet (1860 m²).
2. Where provided with manual control, the following areas are not required to have light reduction control:
   2.1. Spaces that have only one luminaire with a rated power of less than 100 watts.
   2.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m²).
   2.3. Corridors, lobbies, electrical rooms and or mechanical rooms.

Reason: Somehow this section of the code fails to state the obvious: that time-switch controls automatically turn lights off when the space is scheduled to be unoccupied. Instead there is a confusing statement about an “override switching device”, which is describes a relay, but which is usually interpreted by users of the code to be describing a switch which is accessible to occupants. This is doubly-confusing because the list of requirements under C405.2.2.1 is described as establishing requirements for the “override switching device” only, and not for the time-switch system as a whole.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This editorial change clarifies the code intent and will improve compliance and consistency for energy efficient...
automatic lighting shut off control.
IECC: C405.2.2.2

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C405.2.2.2 Light-reduction controls. Spaces required to have light-reduction controls shall have a manual control that allows the occupant to reduce the connected lighting load by not less than 50 percent in a reasonably uniform illumination pattern by not less than 50 percent, with an intermediate step in addition to full on or off, or with continuous dimming control. Lighting reduction shall be achieved by one of the following or another approved method:

1. Controlling all lamps or luminaires.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
3. Switching the middle lamp luminaires independently of the outer lamps.
4. Switching each luminaire or each lamp.

Exception: Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

Reason: Revising this language will:

1. Increase energy efficiency
2. Reduce inconsistency and confusion with light-reduction control requirements
3. Increase code interpretation, application and enforcement
4. Correct an unintended loophole

The ability to reduce light level either by lighting load on/off switch control or by continuous dimming, provides energy savings as well as lighting adjustibility benefits for the occupant. The intent of the provision is to allow space occupants to manually reduce their lighting level by at least 50% of lighting load for personal preference, to avoid glare or simply because full lighting levels is not needed in the space. The light-reduction control requirement has a loophole which allows provision compliance without meeting the intent. Manual lighting controls which turns lighting all the way off, can be interpreted as a reduction of the lighting load of "not less than 50 percent." The way the language is written, full shut off would comply with the provision, but would not meet the intent of the code.

The proposed language would indicate light-reduction control is an intermediate step, in addition to lighting full on and full off control steps, typically provided by manual control requirements. This language eliminates the present loop hole allowing no light reduction control, as the code intends just the opposite. The proposed language also clarifies that continuous dimming would comply with the control requirement while providing further adjustibility benefits to the space occupants.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is an editorial change to clarify the code's intent. It will improve compliance and consistency for energy efficient control of lighting.
CE182-19
IECC: C405.2.2.2

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association
(mar_williams@nema.org)

2018 International Energy Conservation Code
Revise as follows:

C405.2.2.2 Light-reduction controls. Spaces required to have light-reduction controls shall have a manual control that allows the occupant to reduce the connected lighting load in a reasonably uniform illumination pattern by not less than 50 percent. Lighting reduction shall be achieved by one of the following or another approved method:

1. Controlling all lamps or luminaires.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
3. Switching the middle lamp luminaires independently of the outer lamps.
4. Switching each luminaire or each lamp.

Exception: Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

Reason: Revising this language will:
1. Reduce inconsistency and confusion with light-reduction control requirements
2. Reduct energy use
3. Increase code interpretation simplicity
4. Resolve compliance in application, approval and inspection
5. Improve the occupant’s ability to operate their lighting

As the controllability of lighting with LED luminaires has simplified both light reduction and automatic daylight responsive controls, this exception is no longer warranted. Removing this exception allows the light-reduction control provision to become more consistent with user controllability of lighting in areas that have automatic daylight responsive controls. This is a win-win, as the occupants retain more controllability in the space and allows the space to operate more energy efficient by giving occupants control to reduce lighting below levels that daylighting responsive control may adjust them.

A practical example is in an office building. Light level reduction control provides the space user manual control to reduce the lighting through dimming the luminaire or uniformaly switching off some fixtures. However, when the space is required to have daylight responsive controls, the controllability and energy savings may be unnecessarily removed due to this exception. The cost of the lighting controls to accomplish both provisions are the same devices with today’s LED lighting control technology.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is an editorial change to clarify the code’s intent. It will improve compliance and consistency for energy efficient control of lighting.
IECC: C405.2.2.2

Proponent: Marilyn Williams, National Electrical Manufacturers Association, representing National Electrical Manufacturers Association

2018 International Energy Conservation Code

Revise as follows:

C405.2.2.2 Light-reduction controls. Spaces required to have light-reduction controls shall have a manual control that allows the occupant to reduce the general lighting connected lighting load in a reasonably uniform illumination pattern by not less than 50 percent. Lighting reduction shall be achieved by one of the following or another approved method:

1. Controlling all lamps or luminaires.
2. Dual switching of alternate rows of luminaires, alternate luminaires or alternate lamps.
3. Switching the middle lamp luminaires independently of the outer lamps.
4. Switching each luminaire or each lamp.

Exception: Light reduction controls are not required in daylight zones with daylight responsive controls complying with Section C405.2.3.

Reason: Revising this language will:
1. Reduce inconsistency and confusion with light-reduction control requirements
2. Increase code interpretation simplicity.
3. Will not change the intent or requirements of the code provision.

The International Energy Conservation Code has never clarified which type of lighting the C405.2.2.2 Light Reduction Control requirement applies. Other energy efficiency codes explicitly indicate that light reduction control only applies to what is defined as the "general lighting" (defined in the section C202 General Definitions) in the space. It has been common practice and common interpretation of the IECC light reduction control section to only apply it requirements to space general lighting. Yet, since this is not specifically stated, it could be endorsed on other lighting in the space and cause inappropriate confusion and added cost to the construction of buildings.

Application specific lighting or other lighting considered "non-general" lighting, typically cannot be uniformly controlled, nor does it offer a uniform level of illumination to a space that could be easily reduced by at least 50%. These types of lights include under cabinet, supplemental task luminaires, decorative luminaires, wall sconces, display lighting, case lighting, accent lighting and others. The definition of general lighting, states in part, "shall not include decorative lighting or lighting that provides a dissimilar level of illumination to serve a specialized application or feature with such area", highlights lighting not conductive to "reasonably uniform illumination pattern" that is required by the provision.

Specifically including and explicitly providing the language, "general language" in the requirement will reduce the interpretation issues and have the code state correctly, what lighting is required to follow light reduction controls. It will also stop mis-application of the requirement intent and reduce construction cost where this mis-application would have otherwise occurred.
This editorial change clarifies the code intent and will improve compliance and consistency for energy efficient control of lighting.

**Cost Impact:** The code change proposal will decrease the cost of construction. The decrease in the cost of construction is a result of clarifying the appropriate lighting required to have reduced level lighting control and not include the cost of controls for non-general lighting unnecessary, where it is a clear mis-application.

Proposal # 4903

CE183-19
Proponent: Marilyn Williams, representing National Electrical Manufacturers Association

2018 International Energy Conservation Code

Revise as follows:

C405.2.3 Daylight-responsive controls. Daylight-responsive controls complying with Section C405.2.3.1 shall be provided to control the electric lights general lighting within daylight zones in the following spaces:

1. Spaces with a total of more than 150 watts of general lighting within sidelit zones complying with Section C405.2.3.2. General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4.
2. Spaces with a total of more than 240 watts of general lighting within the primary and secondary sidelit zones complying with Section C405.2.3.2.
3. Spaces with a total of more than 150 watts of general lighting within toplit zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance (LPAadj) calculated in accordance with Equation 4-9

\[ LPA_{adj} = \frac{LPA_{norm} \times (1.0 - 0.4 \times UDZFA / TBFA)}{\text{[Equation 4-9]}} \]

where:

- \( LPA_{adj} \) = Adjusted building interior lighting power allowance in watts.
- \( LPA_{norm} \) = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.
- \( UDZFA \) = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.
- \( TBFA \) = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

C405.2.3.1 Daylight-responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:
1. Lights in *toplit zones* in accordance with Section C405.2.3.3 shall be controlled independently of lights in *sidelit zones* in accordance with Section C405.2.3.2.

2. Lights in the primary *sidelit zone* shall be controlled independent of lighting in the secondary *sidelit zone*.

3. *Daylight responsive controls* within each space shall be configured so that they can be calibrated from within that space by authorized personnel.

4. Calibration mechanisms shall be in a location with *ready access*.

5. Where located in offices, classrooms, laboratories and library reading rooms, *daylight responsive controls* shall dim lights continuously from full light output to 15 percent of full light output or lower.

6. *Daylight responsive controls* shall be configured to completely shut off all controlled lights.

7. Lights in *sidelit zones* in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

**Exception:** Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

### C405.2.3.2 Sidelit zone.

The *sidelit zone* is the floor area adjacent to vertical *fenestration* that complies with all of the following:

1. Where the fenestration is located in a wall, the primary *sidelit zone* shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2-feet (610 mm), 1/2 the height from the floor to the top of the fenestration, whichever is less, as indicated in Figure C405.2.3.2.

2. The secondary *sidelit zone* is directly adjacent to the primary *sidelit zone* and shall extend laterally up to 2.0 times, the height from the floor to the top of the fenestration, or to the nearest full height wall, and longitudinally from the edge of the fenestration to the nearest full height wall, or up to 0.5 times the height from the floor to the top of the fenestration, whichever is less, as indicated in Figure C405.2.3.2.

3. The area of the fenestration is not less than 24 square feet (2.23 m²).

4. The distance from the fenestration to any building or geological formation that would block *access to daylight* is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.

5. The visible transmittance of the fenestration is not less than 0.20.
FIGURE C405.2.3.2
SIDELIT ZONE

Reason: Increases energy efficiency and aligns with ASHRAE 90.1 and Title 24 Part 6. General lighting is what must be controlled in a daylight zone, controlled task lighting or decorative lighting can be controlled too but should not be mandatory to do so. Also, the proposal strikes this sentence, "General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4" because it's not needed as the definition of general lighting already says this.

The proposal also slightly lowers the wattage threshold to match what's already been vetted in the Title 24 Part 6 standard. The new 120W threshold better aligns with the use of energy efficient LED lighting and still provide for increased cost-effective energy savings (see cost impact in the attachment).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposed change increases energy efficiency cost-effectively by reducing additional lighting load when lighting is offset by daylight. It increases the cost of construction through the addition of daylight responsive controls for the spaces that use at least 120W of lighting power in a daylight zone, instead of the existing IECC threshold of 150W. Also, note that the addition of a secondary daylight zone does not increase the cost as the same daylight responsive control system to control the lighting in the primary daylight zone can be used to control the lighting in the secondary daylight zone. So, no addition equipment is needed.
Proponent: Jack Bailey, One Lux Studio, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

**C405.2.3.1 Daylight-responsive control function.** Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit zones in accordance with Section C405.2.3.2.
2. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.
3. Calibration mechanisms shall be in a location with ready access.
4. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light output or lower.
5. Daylight responsive controls shall be configured to completely shut off all controlled lights.
6. Lights in sidelit zones in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

**Exception:** Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

**Reason:** Currently daylight responsive controls are only required to dim lights in offices, classrooms, laboratories, and library reading rooms. In all other spaces, daylight responsive controls are only required to switch lights off. Switching lights off leaves a lot of potential energy savings "on the table", as the daylight responsive controls will only save energy when there is sufficient daylight to entirely replace the electric lights. In some installations this may never happen. By contrast, when dimming is required, there will be energy savings whenever there is any useful daylight in the space. Making this change will result in additional energy savings in literally every installation.

This change is feasible today because of the incredibly fast penetration of LED technology into the marketplace. LED luminaires are already almost universally dimmable, and taking advantage of this capability will usually mean running a couple of additional wires. This cost is trivial compared to the cost of installing and commissioning the control systems to begin with.

Functionally, we know that dimming is preferred by building occupants, since the change in light levels is less noticeable, so this will also qualitatively improve the lighting, and increase user acceptance of the controls.

**Cost Impact:** The code change proposal will increase the cost of construction.

Dimming is already the preferred strategy for daylight responsive control of interior lights, and is almost universally used in new construction. With increasing penetration of LED technology in coming years, the cost increase compared to switching will be trivial. But still, there will be some additional cost.
2018 International Energy Conservation Code

Revise as follows:

C405.2.3 Daylight-responsive controls. *Daylight-responsive controls* complying with Section C405.2.3.1 shall be provided to control the electric lights within *daylight zones* in the following spaces:

1. Spaces with a total of more than 150 watts of *general lighting* within sidelit zones complying with Section C405.2.3.2. *General lighting* does not include lighting that is required to have specific application control in accordance with Section C405.2.4.

2. Spaces with a total of more than 150 watts of *general lighting* within toplit zones complying with Section C405.2.3.3.

**Exceptions:** Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance \((LPA_{adj})\) calculated in accordance with Equation 4-9.

\[
LPA_{adj} = \frac{LPA_{norm} \times (1.0 - 0.4 \times UDZFA)}{TBFA}
\]

*(Equation 4-9)*

where:

- \(LPA_{adj}\) = Adjusted building interior lighting power allowance in watts.
- \(LPA_{norm}\) = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.
- \(UDZFA\) = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.
- \(TBFA\) = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

**Reason:** Exception #4 was added to IECC 2018. It created unnecessary complexity with no benefit. It does not improve energy efficiency or the usability of the code -- and actually does the opposite. Exception #4 attempts to solve a problem that does not exist. The “problem” is assumed to be that the installation of daylight responsive controls is an unreasonable burden. This was not the case three years ago, and is not the case.
today. Designers have not, and are not, asking for this exception. We believe that this exception will hurt energy efficiency in the long run by discouraging the use of daylight responsive controls. While designers welcome alternate paths around unreasonable requirements, we do not welcome alternate paths that provide no benefit and only make the code more complex and confusing.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

Because this proposal eliminates an option to avoid the small cost of installing daylight responsive controls (if certain power density limits are met), it could conceivably increase the cost of construction slightly. But this assumes that the option would commonly be taken. We believe that the option currently in the code is unlikely to be used. Daylight responsive controls are standard practice today and we believe will likely be installed anyhow, regardless of whether or not this option is available. Therefore a possible small increase in construction cost is only a hypothetical and not a given.
2018 International Energy Conservation Code

Revise as follows:

C405.2.3 Daylight-responsive controls. Daylight-responsive controls complying with Section C405.2.3.1 shall be provided to control the electric lights general lighting within the following daylight zones in the following spaces:

1. Spaces with Primary sidelit zones where a total of more than 150 watts of general lighting per space are within sidelit zones complying with Section C405.2.3.2 General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4.
2. Secondary sidelit zones where a total of more than 300 watts of general lighting per space are within the primary and secondary sidelit zones complying with Section C405.2.3.2.
3. Toplit zones where spaces with a total of more than 150 watts of general lighting per space are within toplit zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance (LPA_adj) calculated in accordance with Equation 4-9

\[
LPA_{\text{adj}} = \frac{LPA_{\text{norm}} \times (1.0 - 0.4 \times UDZFA / TBFA)}
\]

(Equation 4-9)

where:

- \(LPA_{\text{adj}}\) = Adjusted building interior lighting power allowance in watts.
- \(LPA_{\text{norm}}\) = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.
- \(UDZFA\) = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.
- \(TBFA\) = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

C405.2.3.1 Daylight-responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:
1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit zones in accordance with Section C405.2.3.2.

2. Lights in the primary sidelit zone shall be controlled independently of lights in the secondary sidelit zone.

3. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.

4. Calibration mechanisms shall be in a location with ready access.

5. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light output or lower.

6. Daylight responsive controls shall be configured to completely shut off all controlled lights.

7. Lights in sidelit zones in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

Exception: Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.

2. The secondary sidelit zone is directly adjacent to the primary sidelit zone and shall extend laterally to 2.0 times the height from the floor to the top of the fenestration or to the nearest full height wall whichever is less, and longitudinally from the edge of the fenestration to the nearest full height wall, or up to 2 feet whichever is less, as indicated in Figure C405.2.3.2. If the adjacent primary sidelit zone ends at a full height wall, there is no secondary sidelit zone beyond the wall.

3. The area of the fenestration is not less than 24 square feet (2.23 m$^2$).

4. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.

5. The visible transmittance of the fenestration is not less than 0.20.
Figures C405.2.3.2

**Primary and Secondary Sidelit Zone**

**Reason:** The addition of the secondary sidelit zone to the 2021 IECC would align the IECC with ASHRAE 90.1, California's Title 24 and the Washington State Energy Code. Adding the secondary sidelit zone would increase the energy savings from sidelighting by approximately 33% for little marginal cost since many daylight controls are multi-channel and can use one photosensor and one controller to set different daylight response curves for each channel.

Exception 4 to C405.2.3 is not needed as the measure is cost-effective whenever the total wattage in the daylit zones exceed the 150 watt threshold. Removing this exception would reduce the complexity of enforcing the code.

**Cost Impact:** The code change proposal will increase the cost of construction.

The PNNL cost study found that the secondary sidelit zone only requires an extra power pack since the same sensor and a multi-channel controller can be used. From the CASE study they documented that the addition of the power pack increased the cost of the control system by 25% while doubling the controlled area (but saving about a third of the energy as the secondary zone is further away from windows).
CE188-19

IECC: C405.2.3.1

Proponent: Jonathan McHugh, representing McHugh Energy Consultants Inc. (jon@mchughenergy.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.3.1 Daylight responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of lights in sidelit zones in accordance with Section C405.2.3.2.

2. Daylight responsive controls within each space shall be configured so that they can be calibrated from within that space by authorized personnel.

3. Calibration mechanisms shall be in a location with ready access.

4. Where located in offices, classrooms, laboratories and library reading rooms, daylight responsive controls shall dim lights continuously from full light output to 15 percent of full light output or lower. In all other spaces, daylight responsive controls shall dim lights continuously from full output to 20 percent of full light output or reduce power to between 30 and 70 percent of full power by controlling all luminaires to a reduced light output or by switching alternate luminaires.

5. Daylight responsive controls shall be configured to completely shut off all controlled lights.

6. Lights in sidelit zones in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

Exception: Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

Reason: Currently the IECC daylight-responsive controls requirements includes dimming for a few spaces and for all other spaces, a minimally compliant daylight-responsive control only need turn the lights off under full daylight availability. For light sources that are difficult to dim continuously (such as HID), the savings associated with daylight controls is substantially less than it could be with multi-level controls. Multi-level controls increase energy savings by approximately 50% as compared to on/off controls. This is documented in the CASE sidelifiting and skylighting reports. By allowing other forms of multi-level controls besides continuous dimming, the code is being technology neutral and accommodating light sources that are hard to dim. Requiring multi-levels switching or continuous dimming for daylighting controls is aligned with most other energy codes in the United States including ASHRAE 90.1.

Bibliography:

CASE (Codes and Standards Enhancement Updates to Title 24 Treatment of Skylights. 2005 California Title 24 Building Energy Efficiency Standards. May 2002.

HMG/PNNL 90.1 Skylighting Requirements Code Change Proposal, Submitted to ASHRAE 90.1 Standard
Cost Impact: The code change proposal will increase the cost of construction.

As documented in the HMG/PNNL (2008) report “As a result of discussion with the ASHRAE 90.1 Lighting Subcommittee, the following variable and fixed costs were associated with dimming and switching controls systems. For switching control systems the additional circuiting costs associated with bi-level switching is $0.108/sf..." In comparison for warehouse spaces, the added life cycle savings from using multi-level controls instead of On/Off controls are around $0.25/sf (CASE 2002) and in sidelit spaces the life cycle savings are around $0.50/sf. (CASE 2006). Thus the added costs are well outweighed by the life cycle savings.

2018 International Energy Conservation Code

Revise as follows:

C405.2.3 Daylight-responsive controls. Daylight-responsive controls complying with Section C405.2.3.1 shall be provided to control the electric lights within daylight zones in the following spaces:

1. Spaces with a total of more than 150 watts of general lighting within the primary sidelit zones complying with Section C405.2.3.2. General lighting does not include lighting that is required to have specific application control in accordance with Section C405.2.4.
2. Spaces with a total of more than 300 watts of general lighting within toplit the primary and secondary sidelit zones complying with Section C405.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Lighting that is required to have specific application control in accordance with Section C405.2.4.
3. Sidelit zones on the first floor above grade in Group A-2 and Group M occupancies.
4. New buildings where the total connected lighting power calculated in accordance with Section C405.3.1 is not greater than the adjusted interior lighting power allowance ($LPA_{adj}$) calculated in accordance with Equation 4-9.

$$LPA_{adj} = \left[ LPA_{norm} \times (1.0 - 0.4 \times UDZFA / TBFA) \right]$$

(Equation 4-9)

where:

$LPA_{adj}$ = Adjusted building interior lighting power allowance in watts.

$LPA_{norm}$ = Normal building lighting power allowance in watts calculated in accordance with Section C405.3.2 and reduced in accordance with Section C406.3 where Option 2 of Section C406.1 is used to comply with the requirements of Section C406.

$UDZFA$ = Uncontrolled daylight zone floor area is the sum of all sidelit and toplit zones, calculated in accordance with Sections C405.2.3.2 and C405.2.3.3, that do not have daylight responsive controls.

$TBFA$ = Total building floor area is the sum of all floor areas included in the lighting power allowance calculation in Section C405.3.2.

C405.2.3.1 Daylight-responsive control function. Where required, daylight-responsive controls shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplit zones in accordance with Section C405.2.3.3 shall be controlled independently of
lights in sidelit zones in accordance with Section C405.2.3.2.

2. Lights in the primary sidelit zone shall be controlled independent of lighting in the secondary sidelit zone.

3. *Daylight responsive controls* within each space shall be configured so that they can be calibrated from within that space by authorized personnel.

4. Calibration mechanisms shall be in a location with *ready access*.

5. Where located in offices, classrooms, laboratories and library reading rooms, *daylight responsive controls* shall dim lights continuously from full light output to 15 percent of full light output or lower.

6. *Daylight responsive controls* shall be configured to completely shut off all controlled lights.

7. Lights in *sidelit zones* in accordance with Section C405.2.3.2 facing different cardinal orientations [within 45 degrees (0.79 rad) of due north, east, south, west] shall be controlled independently of each other.

**Exception:** Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

**C405.2.3.2 Sidelit primary and secondary zone.** The sidelit zone is the floor area adjacent to vertical *fenestration* that complies with all of the following:

1. Where the fenestration is located in a wall, the primary sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2-feet (610 mm) 0.5 times the height from the floor to the top of the fenestration, whichever is less, as indicated in Figure C405.2.3.2.

2. The secondary sidelit zone is directly adjacent to the primary sidelit zone and shall extend laterally from 1.0 times to 2.0 times the height from the floor to the top of the fenestration to the nearest full height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full height wall, or up to 0.5 times the height from the floor to the top of the fenestration, whichever is less, as indicated in Figure C405.2.3.2. If the adjacent primary sidelit zone ends at a full height wall, there is no secondary sidelit zone beyond such obstruction.

3. The area of the fenestration is not less than 24 square feet (2.23 m²).

4. The distance from the fenestration to any building or geological formation that would block *access to daylight* is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.

5. The visible transmittance of the fenestration is not less than 0.20.

*Delete and substitute as follows:*
FIGURE C405.2.3.2
SIDELIT-ZONE

(a) Section A
(b) Front view of daylight zone under a rooftop monitor
FIGURE C405.2.3.2
SIDELIT ZONE

**Reason:** Revising this language will:
1. Reduce inconsistency and application confusion with daylight responsive controls
2. Reduce energy use
3. Increase code interpretation
4. Resolve compliance in application, approval and inspection
5. Simplify design and compliance by aligning with other energy efficiency codes.

The contribution of daylight through vertical fenestration (windows) into a space, extends laterally much further into the space than the current code’s defined area for a single sidelight daylight zone. In many applications, the change in the 2015 IECC definition of daylighting zones reduced the daylighting area, yet daylight can still project much further into the side lighting space. A secondary sidelit daylighting zone can further reduce the electric lighting level in response to daylighting contribution to this area, saving added energy.

Evaluation studies performed by the Pacific Northwest National Laboratory extensively reviewed the viability of a secondary daylighting zone across six climate zones, four common window to wall ratios, with and without blinds, and with nine visual lighting transmission ratios. A secondary daylighting zone was determined to be cost effective down to 120 watts of controlled power.

For simplicity of the code and compliance, this secondary sidelit zone is the same dimension, and sits adjacent to the primary sidelit zone, and parallel to the wall fenestration. The primary and secondary daylighting controls operate independently to adjust electric lighting given the differing daylight level contributions in each zone. The controls maintain space occupant visual acuity and comfort by maintaining the design foot candle levels.

By requiring the toplit and sidelit daylight zones to be shown on the construction documents, it simplifies inspection and enforcement of this provision.

**Cost Impact:** The code change proposal will increase the cost of construction. This proposed change increases energy efficiency by reducing additional space lighting power with the offset of daylight further into the building space than the primary sidelit zone.

Feasibility and cost studies were conducted in the cited research “Daylighting Analysis for ASHRAE 90.1 Code Development”. In the cost feasibility, the research incorporated the added cost of photocontrols, installation and commissioning. This cost analysis comprehensively included both the fixed control costs and variable costs of wiring and installation, with the number of fixtures, at standard Union Electrician Labor Rates. Averaging across climate zones, typical window to wall ratios, and average building orientations, the study showed adding a secondary daylight area increases cost effectiveness over just a primary sidelight daylight area. Using the typical nine-year scaler, the benefit to cost ratio for a building with 0.2 visible light transmittance (fairly low transmittance) demonstrated a breakeven point at 120W of lighting controlled with only a primary daylighting area. When the secondary daylighting area was included, the breakeven point dropped to 100W of lighting controlled. The current code threshold is at 150W controlled lighting, well above the cited breakeven points, thus putting the Benefit Cost Ratio at 1.2 for adding the secondary daylighting area at 150W of lighting controlled.
2018 International Energy Conservation Code

Revise as follows:

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.
2. The area of the fenestration is not less than 24 square feet (2.23 m²).
3. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than one half of the height from the bottom of the fenestration to the top of the building or geologic formation.
4. The visible transmittance of the fenestration is not less than 0.20.

Reason: This change would greatly expand the applicability of daylight responsive controls requirements in cities, where there is significant overshadowing from adjacent buildings, and would conform the requirements in the IECC to those in Standard 90.1 and California T24. For buildings in urban areas, daylight responsive controls would be required on lower floors of buildings where they are currently not required.

Cost Impact: The code change proposal will increase the cost of construction

This proposal would increase the cost of construction by expanding the scope daylight responsive controls requirements.

Proposal # 4785

Revise as follows:

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the primary sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2-feet (610 mm) 1/2 the height from the floor to the top of the fenestration, whichever is less, as indicated in Figure C405.2.3.2.
2. The area of the fenestration is not less than 24 square feet (2.23 m²).
3. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.
4. The visible transmittance of the fenestration is not less than 0.20.

Delete and substitute as follows:
FIGURE C405.2.3.2
SIDELIT ZONE
Figure C405.2.3.2

**SIDELIT ZONE**

**Reason:** Revising this language will:
1. Reduce inconsistency and application confusion with daylight responsive controls
2. Reduce energy use for taller vertical fenestrations
3. Resolve compliance in application, approval and inspection.
4. Simplify design and compliance by aligning with other energy efficiency codes.

By changing the sidelit daylighting zone horizontal dimension from two feet from the vertical fenestration, to one half times the window head height, the provision aligns with the sidelit zone dimension of other energy codes. The changes will simplify application and enforcement through consistent sidelit zone dimensioning across energy codes. In many cases, the sidelit daylighting zone area becomes either smaller or larger depending on the head height of the window. The proposed change allows the horizontal dimension beyond the vertical fenestration to dynamically scale based on the amount of daylight entering the space due to vertical fenestration head height instead of being a static two feet which could be too much or not enough distance for daylighting to enter the space.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Changing the definition of the daylighting area to align with other codes will slightly expand the instances when the sidelit daylighting area will reach the 150W lighting power threshold. As a result, some sidelit daylighting...
areas which would not have had to apply the cost of daylighting controls before this change, will now require daylighting controls in the building construction. The benefit for energy efficiency increases in these instances, and the cost effectiveness for the controls remains the same as before this code change. As cited in daylighting research study “Daylighting Analysis for ASHRAE 90.1 Code Development” by PNNL and Heschong Mahone Group, a cost to benefit ratio of 1.2 (1.0 or less is breakeven) is achieved in buildings of average window to wall ratio, averaged climate zones and with visual light transmittance of 0.2.

Proposal # 4442

2018 International Energy Conservation Code

Revise as follows:

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.
2. The area of the fenestration is not less than 24 square feet (2.23 m²).
3. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.
4. The visible transmittance of the fenestration is not less than 0.20.
5. Where the fenestration is shaded by an overhanging projection and the projection factor determined in accordance with Equation 4-5 is not greater than 1.0 for fenestration oriented 45 degrees or less from true north and not greater than 1.5 for all other orientations.

Reason: Currently there is no exception from daylight responsive controls requirements for windows shaded by deep overhangs. This proposal would create an exception, by stating that a daylight zone is not established if the exterior overhang is too deep.

The exception varies based on façade orientation, with a shallower projection required on the north façade than on the east, south, and west. The language proposed here “oriented 45 degrees or less from true north” is very similar to the language in Table C402.4 “oriented within 45 degrees of true north”. We prefer “45 degrees or less” because it is clear how to treat a building façade oriented exactly 45 degrees from true north.

Cost Impact: The code change proposal will decrease the cost of construction Where there is a deep overhanging projection, there will no longer be a requirement to install daylight responsive controls.

Proposal # 4988

2018 International Energy Conservation Code

Revise as follows:

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.
2. Where the fenestration is located in a rooftop monitor, the sidelit daylight zone shall extend laterally to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 1.0 times the height from the floor to the bottom of the fenestration, whichever is less, and longitudinally from the edge of the fenestration to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.25 times the height from the floor to the bottom of the fenestration, whichever is less, as indicated in Figures C405.2.3.2(1) and C405.2.3.2(2).
3. The area of the fenestration is not less than 24 square feet (2.23 m²).
4. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.
5. The visible transmittance of the fenestration is not less than 0.20.

C405.2.3.3 Toplit zone. The toplit zone is the floor area underneath a roof fenestration assembly that complies with all of the following:

1. The toplit zone shall extend laterally and longitudinally beyond the edge of the roof fenestration assembly to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.7 times the ceiling height, whichever is less, as indicated in Figure C405.2.3.3(1).
2. Where the fenestration is located in a rooftop monitor, the toplit zone shall extend laterally to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 1.0 times the height from the floor to the bottom of the fenestration, whichever is less, and longitudinally from the edge of the fenestration to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.25 times the height from the floor to the bottom of the fenestration, whichever is less, as indicated in Figures C405.2.3.3(2) and C405.2.3.3(3).
3. Direct sunlight is not blocked from hitting the roof fenestration assembly at the peak solar angle on the summer solstice by buildings or geological formations.
4. The product of the visible transmittance of the roof fenestration assembly and the area of the rough opening of the roof fenestration assembly divided by the area of the toplit zone is not less than 0.008.
FIGURE C405.2.3.3 C405.2.3.3(2.1)
DAYLIGHT ZONE UNDER A ROOFTOP MONITOR

(a) Section view
(b) Plan view of daylight zone under a rooftop monitor
Reason: The language describing daylight zones under rooftop monitors was relocated from the “sidelit” to the “toplit” section in the 2018 IECC. This was a mistake. The requirements for overshadowing, VT, and fenestration area in the toplit section cannot be sensibly applied to rooftop monitors, and were never intended to be applied to rooftop monitors. By contrast, the requirements for overshadowing, VT, and fenestration area in the sidelit section are applicable.

This proposal also clarifies that “vertical fenestration” is a defined term, by adding italics. For rooftop monitors with sloped glazing, this definition is beneficial because it creates a clear distinction between a “rooftop monitor” and a skylight (i.e. a “rooftop monitor” has vertical fenestration which, by definition, is “installed at a slope of not less than 60 degrees from the horizontal”).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposed change is a clarification of code intent.

Proposal # 4786
CE194-19
IECC: FIGURE C405.2.3.2

(mar_williams@nema.org)

2018 International Energy Conservation Code
Revise as follows:
(b) Plan view of daylight zone under a rooftop monitor

(b) Plan view

FIGURE C405.2.3.2
SIDELIT ZONE

Reason: Editorial change to correct mis-label of daylighting sidelit zone figure.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost impact. This change is editorial.

Proposal # 4396

CE194-19
2018 International Energy Conservation Code

Revise as follows:

C405.2.3.2 Sidelit zone. The sidelit zone is the floor area adjacent to vertical fenestration that complies with all of the following:

1. Where the fenestration is located in a wall, the sidelit zone shall extend laterally to the nearest full-height wall, or up to 1.0 times the height from the floor to the top of the fenestration, and longitudinally from the edge of the fenestration to the nearest full-height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.2.3.2.
2. The area of the fenestration is not less than 24 square feet (2.23 m²).
3. The distance from the fenestration to any building or geological formation that would block access to daylight is greater than the height from the bottom of the fenestration to the top of the building or geologic formation.
4. The visible transmittance of the fenestration is not less than 0.20.
5. For fenestration shaded by an overhang projection with vertical fenestration above the projection, the projection factor, as determined in accordance with Equation 4-5 in Section C402.4.3, is not greater than 1.0 for fenestration oriented less than 45 degrees from North and not greater than 1.5 for all other orientations.

Reason: Revising this language will:

1. Clarify how a daylighting sidelit zone is determined when there is an overhang or shading projection associated with the sidelit zone vertical fenestrations.
2. Eliminate daylighting sidelit zones where adequate daylight is not available to justify daylight responsive controls installation.
3. Increase code interpretation simplicity for sidelit daylight zones.

Cost Impact: The code change proposal will decrease the cost of construction
Where there is an overhang of adequate projection factor (PF), it will not be required to install daylight responsive controls.
2018 International Energy Conservation Code

Add new text as follows:

**C405.2.3.4 Atriums** Daylight zones at atrium spaces shall be established at the top floor surrounding the atrium and at the floor of the atrium space, and not on intermediate floors, as indicated in Figure C405.2.3.4.
**FIGURE C405.2.3.4**

**DAYLIGHT ZONES AT A MULTISTORY ATRIUM**

**Reason:** Currently the code provides no guidance as to how daylight zones would be established in multistory atrium spaces. This proposal provides clarity.
It seems reasonable that roof-mounted fenestration would not establish daylight zones on intermediate floors of an atrium, because of shadowing from each floor slab onto the floor below.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposed change is a clarification
CE197-19

IECC: C405.2.6, C405.2.6.2

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code

Revise as follows:

C405.2.6 Exterior lighting controls. Exterior lighting systems shall be provided with controls that comply with Sections C405.2.6.1 through C405.2.6.4. Decorative lighting systems shall comply with Sections C405.2.6.1, C405.2.6.2 and C405.2.6.4.

Exceptions:

1. Lighting for covered vehicle entrances and exits from buildings and parking structures where required for eye adaptation.
2. Lighting controlled from within dwelling units.

C405.2.6.2 Decorative lighting shutoff. Building facade and landscape lighting. Building facade and landscape lighting shall automatically shut off from not later than 1 hour after business closing to not earlier than 1 hour before business opening.

Reason: The use of the term “decorative” lighting for exterior applications is confusing. We have interior “decorative” lighting described in CC405.3.2.2.1, but no exterior “decorative” lighting. The requirements of Section C405.2.6.2 refer specifically to building façade and landscape lighting, and these are the terms we should use. The second sentence in C405.2.6 is not necessary, as it has no effect.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is an editorial clarification.

Proposal # 4789
CE198-19
IECC: C405.2.6.3

Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

Revise as follows:

C405.2.6.3 Lighting setback. Lighting that is not controlled in accordance with Section C405.2.6.2 shall be comply with the following:

1. Be controlled so that the total wattage of such lighting is automatically reduced by not less than 50 percent by selectively switching off or dimming luminaires at one of the following times:
   1.1. From not later than midnight to not earlier than 6 a.m.
   1.2. From not later than one hour after business closing to not earlier than one hour before business opening.
   1.3. During any time where activity has not been detected for 15 minutes or more.

2. Luminaires serving outdoor parking areas and having a rated input wattage of greater than 78 W and a mounting height of 24 feet or less above the ground shall be controlled so that the total wattage of such lighting is automatically reduced by not less than 50 percent during any time where activity has not been detected for 15 minutes or more. No more than 1500 W of lighting power shall be controlled together.

Reason: Parking lot lighting offers more controllability and energy efficiency through the prolific use of solid state light sources. In prior versions of the IECC, the lighting setback control to reduce lighting wattage was limited to just 30% due to legacy lighting source limitations. Solid state lighting sources now allow a greater control range and dimmability of exterior luminaires than in the past. Changing the wattage reduction from 30 to 50% maintains sufficient exterior illumination after business operating hours when occupancy is reduced, yet is able to save an additional 20% in lighting wattage over the prior IECC versions. A 50% lighting setback wattage reduction has been part of other energy codes for a number of years. This change allows the IECC to remain consistent with the practice and efficiency of other codes.

Providing lighting when it is needed, through activity detection, has been long proven as one of the most efficient and effective ways to control lighting. In outdoor environments, as parking lots, detection technology is widely available. Many outdoor luminaires come with options to include detection technology directly integrated in the luminaire. These controls add some cost to the parking lot luminaires, but offer good payback. The amount of occupancy in parking lots ranges by exterior use type. Office building exteriors show 29% occupancy (using the proposed 15 minute time delay) during normally scheduled occupancy of 6pm to midnight. This allows lighting that might normally be at 100% to be reduced to 50% for 71% of the time, when controlled by activity detection. By comparison, an outdoor shopping center experiences a 79% occupancy. Even with this broad range of exterior occupancy rates, there still remains consider opportunity to reduce the lighting level with minimal impact to use.

Bibliography: Nonresidential Outdoor Lighting Controls, Codes and Standards Enhancement Initiative, Measure Number: 2019-NR-LIGHT3F, September 2017

Outdoor Lighting and Controls, Codes and Standards Enhancement Initiative, California Utilities Statewide Codes and Standards Team, October 2011
Cost Impact: The code change proposal will increase the cost of construction.
This proposal increases the cost of construction due to the lighting controls needed for this requirement. This proposed change increases energy efficiency by an additional 20% during after hour periods and when there is no occupancy in the occupancy sensor-controlled area and provides payback for the increased cost of construction.

Proposal # 4855

CE198-19
CE199-19
IECC: C405.2.7 (New)

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association
(mar_williams@nema.org)

2018 International Energy Conservation Code

Add new text as follows:

C405.2.7 Parking Garage Lighting Control. Lighting for parking garage shall comply with the following:

1. Parking garage lighting shall have automatic time-switch shutoff in accordance with Section C405.2.2.1.
2. Lighting power of each luminaire shall be automatically reduced by not less than 30% when there is no
   activity detected within a lighting zone for 20 minutes. Lighting zones for this requirement shall be no
   larger than 3600 ft².
3. Where lighting for eye adaptation is provided at covered vehicle entrances and exits from buildings and
   parking structures, such lighting shall be separately controlled by a device that automatically reduces
   lighting power by at least 50% from sunset to sunrise.
4. The power to luminaires within 30 ft of perimeter wall openings or fenestration shall automatically reduce
   in response to daylight by at least 50%.

Exceptions:

1. Where the opening or fenestration-to-wall-ratio is less than 40% as viewed from the interior
   and encompassing the vertical distance from the driving surface to the lowest structural
   element.
2. Where the distance from the opening or fenestration to any exterior daylight blocking
   obstruction is less than one-half the height from the bottom of the opening or fenestration to
   the top of the obstruction.
3. Where openings are obstructed by permanent screens or architectural elements restricting
   daylight entering the interior space.

Reason: Adding this language will:
1. Reduce inconsistency and confusion with the application of lighting controls in parking garages.
2. Align code language and implementation with other energy efficiency codes.
3. Reduce energy use.
4. Resolve compliance in application and inspection.

Currently there is confusion on how to apply the requirements of the 2018 IECC to parking garage applications. Is it to be treated as a interior space, and if so, how are the control requirements applied that has different use needs that building interior spaces? The Daylight Responsive Controls of section C405.2.3 do not provide proper guidance for how to control lighting in a parking garage setting. This proposal provides proper daylight responsive control and exceptions that meet the design needs and operation of parking garages.

There is some relative increase in cost due to adding occupancy sensing control to reduce the lighting level when there is no activity in controlled lighting zones.
Adding a parking garage specific control section, there is improved clarity in parking garage application, increased energy efficiency in lighting operation and better compliance through requirements that meet the application needs of parking garages.

**Cost Impact:** The code change proposal will increase the cost of construction
The code change proposal will increase the cost of construction. Proposed language is mostly a clarification and editorial in nature. There is a small increase in construction cost with the added controls for partial automatic off that provide a payback during the long operating hours of a parking garage structure.
CE200-19
IECC: C405.3, C405.4

Proponent: Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com); Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

2018 International Energy Conservation Code
Revise as follows:

C405.3 Interior lighting power requirements (Prescriptive). A building complies with this section where its total connected interior lighting power calculated under Section C405.3.1 is not greater than the interior lighting power allowance calculated under Section C405.3.2. For the purposes of this determination, all building floor area which is under the horizontal projection of the roof or floor above shall be considered interior, and all lighting serving that floor area shall be considered interior lighting.

C405.4 Exterior lighting power requirements (Mandatory). The total connected exterior lighting power calculated in accordance with Section C405.4.1 shall be not greater than the exterior lighting power allowance calculated in accordance with Section C405.4.2. For the purposes of this determination, all building floor area which is not under the horizontal projection of the roof or floor above shall be considered exterior, and all lighting serving that floor area shall be considered exterior lighting.

Reason: Under the current code how do we know whether lighting is “interior” or “exterior”? This is not discussed anywhere in the code, so users are currently free to make their own assumptions. Consider these examples:

1. Unenclosed lobbies, corridors, and retail and airport concourses in milder climates are most often considered “interior” spaces if they are under a roof, even though they are not conditioned.
2. Lower floors of open air parking garages are considered “interior” spaces (and the allowance for these is located in the interior lighting power tables C405.3.2(1) and C405.3.2(2).
3. The roof of a parking garage is considered “exterior” space, and the allowance for this is located in the exterior lighting power table C405.4.2(2).
4. Rooftop terraces are most often considered “exterior” even though this is occupiable building floor area.
5. Spaces under trellises and canopies on building sites are most often considered exterior.
6. Rooftop terraces and open air courtyards are most often considered exterior.

The proper classification of lighting is important for both lighting power and controls determinations under the code.

Any proposal on this subject matter is bound to challenge some people’s assumptions about how lighting should be classified, and this is inevitable when we try to bring everyone to a common understanding of this topic. It is also inevitable that some of the determinations will seem arbitrary.

The proposed language “under the horizontal projection of the roof or floor above” is borrowed from the IBC definition of “gross floor area” which uses similar language:

From the 2018 IBC:

**[BE] FLOOR AREA, GROSS.** The floor area within the inside perimeter of the exterior walls of the building under consideration, exclusive of vent shafts and courts, without deduction for corridors, stairways, ramps, closets, the thickness of interior walls, columns or other features. The floor area of a building, or portion thereof,
not provided with surrounding exterior walls shall be the usable area under the horizontal projection of the roof or floor above. The gross floor area shall not include shafts with no openings or interior courts.

This proposal is clear, and should align the language of the code with the way it is most often interpreted for the most common applications.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This aligns the text of the code with the way it is most often applied.

Proposal # 4791

CE200-19
CE201-19

IECC: C405.3.1

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association
(mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C405.3.1 Total connected interior lighting power. The total connected interior lighting power shall be
determined in accordance with Equation 4-10.

\[ TCLP = [LVL + BLL + LED + TRK + Other] \]  
(Equation 4-10)

where:

- **TCLP** = Total connected lighting power (watts).
- **LVL** = For luminaires with lamps connected directly to building power, such as line voltage lamps, the rated wattage of the lamp.
- **BLL** = For luminaires incorporating a ballast or transformer, the rated input wattage of the ballast or transformer when operating that lamp.
- **LED** = For light-emitting diode luminaires with either integral or remote drivers, the rated wattage of the luminaire.
- **TRK** = For lighting track, cable conductor, rail conductor, and plug-in busway systems that allow the addition and relocation of luminaires without rewiring, the wattage shall be one of the following:
  1. The specified wattage of the luminaires, but not less than 8 W per linear foot (25 W/lin m).
  2. The wattage limit of the permanent current-limiting devices protecting the system.
  3. The wattage limit of the transformer supplying the system.
- **Other** = The wattage of all other luminaires and lighting sources not covered previously and associated with interior lighting verified by data supplied by the manufacturer or other approved sources.

The connected power associated with the following lighting equipment and applications is not included in
calculating total connected lighting power.

1. Television broadcast lighting for playing areas in sports arenas.
2. Emergency lighting automatically off during normal building operation.
3. Lighting in spaces specifically designed for use by occupants with special lighting needs, including those with visual impairment and other medical and age-related issues.
4. Casino gaming areas.
5. Mirror lighting in dressing rooms.
6. Task lighting for medical and dental purposes that is in addition to general lighting and controlled by an independent control device.
7. Display lighting for exhibits in galleries, museums and monuments that is in addition to general lighting and controlled by an independent control device.
8. Lighting for theatrical purposes, including performance, stage, film production and video production.
10. Lighting integral to equipment or instrumentation and installed by the manufacturer.
11. Task lighting for plant growth or maintenance.
12. Advertising signage or directional signage.
13. Lighting for food warming.
14. Lighting equipment that is for sale.
15. Lighting demonstration equipment in lighting education facilities.
16. Lighting approved because of safety considerations.
17. Lighting in retail display windows, provided that the display area is enclosed by ceiling-height partitions.
18. Furniture-mounted supplemental task lighting that is controlled by automatic shutoff.
19. Exit signs.
20. Antimicrobial lighting used for the sole purpose of disinfecting a space.

Reason: One traditional type of indoor connected power exemptions has been the use of lighting for non-human, non-visual applications as exampled by food warming or plant growth. New technology is emerging for another non-human, non-visual application using narrow-wavelength high density violet light just above 400 nm to disinfect a space by eliminating a range of common pathogens susceptible to this band. Lighting developed specifically for this purpose is on during times of vacancy and off during occupancy. This type of application is not only important in medical facilities but can also be used in locker rooms, restrooms, and kitchen areas to improve the general health and well being of those in a space. Without a directly defined exemption, this new technology for improving the general health could come into conflict with today’s energy codes, depending on interpretation.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal will neither increase or decrease the cost of construction. No cost impact to the normally specified architectural lighting installation with a space. Customers looking for this type of implementation would buy separate of specified architectural lighting.
IECC: C405.3.2, C405.3.2.2

Proponent: Glenn Heinmiller, Lam Partners, representing Self (glenn@lampartners.com); Jack Bailey, representing International Association of Lighting Designers (jbailey@oneluxstudio.com)

2018 International Energy Conservation Code

Revised as follows:

C405.3.2 Interior lighting power allowance. The total interior lighting power allowance (watts) is determined according to Table C405.3.2(1) using the Building Area Method, or Table C405.3.2(2) using the Space-by-Space Method, for all areas of the building covered in this permit. Buildings with unfinished spaces shall use the Space-by-Space Method.

C405.3.2.2 Space-by-Space Method. For the Space-by-Space Method, the interior lighting power allowance is determined by multiplying the floor area of each space times the value for the space type in Table C405.3.2(2) that most closely represents the proposed use of the space, and then summing the lighting power allowances for all spaces. Where a building has unfinished spaces, the lighting power allowance for the unfinished spaces shall be the total connected lighting power for those spaces, or 0.2 watts per square foot, whichever is less. Tradeoffs among spaces are permitted.

Reason: This proposal clarifies how the lighting power allowance is to be determined for Core and Shell buildings. This is the source of much legitimate confusion. While there are a variety of strategies for permitting and obtaining certificate of occupancy in core and shell buildings with unfinished spaces, we are concerned about one scenario in particular: where tenant spaces are provided with minimal lighting to meet the egress requirements of the IBC so that a permit can be “closed out”, with the intention that this lighting will be replaced when a tenant leases the space and does their own fitout with permanent lighting. In these situations it is quite easy to "game" the code by taking an allowance for the intended use of the space (i.e. retail, office, etc.) while only counting the minimal lighting that is installed to obtain a certificate of occupancy. This is a major loophole.

This change requires that the space-by-space method be used for buildings with unfinished spaces. The Building Area Method cannot be used in this case because the power allowances for each Building Area Type are based on the allocation of space types in a typical building of that building type (Office, Retail, etc.) and it is assumed that all spaces are finished. The space-by-space method is the only way to break out the unfinished spaces and assign a power allowance for those spaces.

The proposed language will be clear in all instances, and will prevent people from claiming credit for fictitious savings in lighting power in unfinished spaces.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This proposal provides clarity on the application of the code and closes a potential loophole.

Proposal # 4790

CE202-19
2018 International Energy Conservation Code

Revise as follows:

C405.3.2 Interior lighting power allowance. The total interior lighting power allowance (watts) for an entire building shall be determined according to Table C405.3.2(1) using the C405.3.2.1 Building Area Method, or Table C405.3.2(2) using the Space-by-Space Method, for all areas of the building covered in this permit.

C405.3.2.2 Space-by-Space method. The interior lighting power allowance for projects that only involve portions of a building shall be determined according C405.3.2.2 Space-by-Space Method.

Delete and substitute as follows:

C405.3.2.1 Building Area Method. For the Building Area Method, the interior lighting power allowance is the floor area for each building area type listed in Table C405.3.2(1) times the value from Table C405.3.2(1) for that area. For the purposes of this method, an “area” shall be defined as all contiguous spaces that accommodate or are associated with a single building area type, as listed in Table C405.3.2(1). Where this method is used to calculate the total interior lighting power for an entire building, each building area type shall be treated as a separate area.

C405.3.2.1 Building Area Method. For the Building Area Method, the interior lighting power allowance is calculated as follows:

1. For each building area type inside the building, determine the applicable building area type and the allowed lighting power density for that type from Table C405.3.2(1). For building area types not listed, select the building area type that most closely represents the use of that area. For the purposes of this method, an "area" shall be defined as all contiguous spaces that accommodate or are associated with a single building area type.

2. Determine the floor area for each building area type listed in Table C405.3.2(1) and multiply this area by the applicable value from Table C405.3.2(1) to determine the lighting power (watts) for each building area type.

3. The total interior lighting power allowance (watts) for the entire building is the sum of the lighting power from each building area type.

C405.3.2.2 Space-by-Space Method. For the Space-by-Space Method, the interior lighting power allowance is determined by multiplying the floor area of each space times the value for the space type in Table C405.3.2(2) that most closely represents the proposed use of the space, and then summing the lighting power allowances for all spaces. Tradeoffs among spaces are permitted.

C405.3.2.2 Space-by-Space Method. For the Space by-Space Method, the interior lighting power allowance is calculated as follows:

1. For each space enclosed by partitions that are not less than 80 percent of the ceiling height, determine the applicable space type from Table C405.3.2(2). For space types not listed, select the space type that most closely represents the proposed use of the space. Where a space has multiple functions, that space may be divided into separate spaces.

2. Determine the total floor area of all the spaces of each space type and multiply by the value for the space type in Table C405.3.2(2) to determine the lighting power (watts) for each space type.
3. **The total interior lighting power allowance (watts) shall be the sum of the lighting power allowances for all space types.**

**Reason:** This proposal clarifies the application and calculation procedures for the Building Area Method and the Space-by-Space Method. Currently the code does not provide clear or complete direction. There is no change in stringency.

This proposal specifically clarifies these items which have been a source of confusion and misunderstanding:

- The Building Area Method may only be used to determine compliance for an entire building. This is because the Building Area method power allowances are based on the typical mix of space types within an entire building of that building type.
- The Space-by-Space Method does not require the determination of the area and power of each individual space, but rather the total area and total power for all of the spaces of each space type.

This proposal makes this calculation procedure easier to understand and will increase the usability of the code. Codes which are usable are more likely to be complied with and are easier to enforce.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This proposal is a re-write to clarify code requirements.

**Reason:** This proposal updates the LPD tables in the IECC to reflect advancements in lighting technology and lighting design practices. A majority of these values are from ASHRAE 189.1-2018 but some values were modified based on discussions with lighting designers and other stakeholders as part of the New York Stretch.
Code development process. A majority of these changes are driven by how IALD space type definitions have not kept pace with how spaces and lighting needs are evolving. Airport concourses is one such notable examples.

**Cost Impact:** The code change proposal will increase the cost of construction. This proposal may represent an increase in cost for affected space and building types depending on current practice of the lighting designer and lighting suppliers. Higher efficacy light sources will be required to meet the proposed lighting power densities which may cost more than was is currently used in particular market.

Proposal # 5191

CE204-19
2018 International Energy Conservation Code

a. Where sleeping units are excluded from lighting power calculations by application of Section R405.1, neither the area of the sleeping units nor the wattage of lighting in the sleeping units is counted.

b. Where dwelling units are excluded from lighting power calculations by application of Section R405.1, neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.

c. Dwelling units are excluded. Neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.

**Reason:** The results here reflect advances in lighting technology from a number of sources including the New York stretch code, California's Title 24 and ASHRAE 90.1 and 189.1.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The LPDs here reflect LED technology. Almost all new lighting projects are using LEDs. The costs of LEDs have dropped significantly and the market share of competing technologies has declined. Since some lighting designers "design to code" in some cases this may result in less products being installed for a cost savings.
Proponent: Connor Barbaree, representing ASHRAE (cbarbaree@ashrae.org)

2018 International Energy Conservation Code

Where sleeping units are excluded from lighting power calculations by application of Section R405.1, neither the area of the sleeping units nor the wattage of lighting in the sleeping units is counted.

Where dwelling units are excluded from lighting power calculations by application of Section R405.1, neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.

dwelling units are excluded. Neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.

Reason: Building Area Method Lighting Power Densities (LPDs) are based on the Space-by-Space LPDs assigned proportionally for the building type. The LPD values proposed here are a continuation of the extensive work done on the Space-by-Space LPD values. The Space-by-space LPD values are not just an update to existing models, but instead, include an extensive review and upgrade of those models. The work included: · Evaluation of current Illuminating Engineering Society (IES) guidelines for lighting of commercial interiors (recommended footcandles, or illuminance, at the work plane) for all spaces. The ANSI/IES Recommended Practice (RP28-2016 for Seniors and the Low Vision Population) was used to inform both illuminance levels and fixture selection for space types in Facilities for the Visually Impaired. · Expansion of categories used to assign room surface reflectance for each space type, based on actual usage, not just design “rules of thumb.”· Previously, most spaces were assumed to have ceiling surfaces of 70% reflectance, wall surfaces of 50% reflectance and floor surfaces of 20% reflectance (70/50/20). Through a consensus process, the developers of this proposal agreed to select the wall surface reflectance as the primary surface. Many spaces were reassigned to the category of 50/30/20 reflectance and some were reassigned to the 30/10/20 category. · Update and expansion of the lighting fixture database. 100% of the fixtures are solid state (LED), using current off-theshelf technology (fixture efficacy) · Improvement of the high color quality data set for LED fixtures used in spaces that previously had incandescent, halogen or premium HID · Standardization on a Light Loss Factor for LED of 0.85, not the End of Useful Life metric of 0.70 · Improvement of the wallwashing methodology for spaces where vertical surface illumination was deemed important Additionally, the building data set, developed using Dodge Data & Analytics and the National Construction Database, was reviewed to assure that the actual buildings assigned to each Building type better reflected that Building type. It was agreed by the developers of this proposal that a filter should be applied (where possible) based on the criteria that at least 33% of the underlying space-by-space data must represent spaces that are the larger Building Area category. Previously, if the space-by-space mixture contained a large portion of spaces that differed from the larger Building Area category, it could result in a Building Area LPD value that was significantly different from the appropriate Space-by-Space LPDs. The values proposed here are a better composite of the spaces. The overall reduction across all building types will result in energy savings of approximately 5% over IECC 2018.

Bibliography: Addendum CG to ASHRAE Standard 90.1-2016

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The code change proposal will not increase or decrease the cost of construction. The Lighting Power Density values proposed in this code change proposal utilize off-the-shelf current LED technology and do not require additional or more expensive luminaries. The efficacy chosen for the models was based on the average of a fixture data set using luminaires from multiple manufacturers. Specifiers and users can find light fixtures that will allow the project to meet code at reasonable price points. Data gathered from industry partners indicates that product development is all directed at solid-state (LED) lighting with many traditional fixtures and lamp sources being discontinued.

a. In cases where both a common space type and a building area specific space type are listed, the building area specific space type shall apply.
b. A ‘Facility for the Visually Impaired’ is a facility that is licensed or will be licensed by local or state authorities for senior long-term care, adult daycare, senior support or people with special visual needs.
c. Where sleeping units are excluded from lighting power calculations by application of Section R405.1, neither the area of the sleeping units nor the wattage of lighting in the sleeping units is counted.
d. Where dwelling units are excluded from lighting power calculations by application of Section R405.1, neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.
e. Class I facilities consist of professional facilities; and semiprofessional, collegiate, or club facilities with seating for 5,000 or more spectators.
f. Class II facilities consist of collegiate and semiprofessional facilities with seating for fewer than 5,000 spectators; club facilities with seating for between 2,000 and 5,000 spectators; and amateur league and high-school facilities with seating for more than 2,000 spectators.
g. Class III facilities consist of club, amateur league and high-school facilities with seating for 2,000 or fewer spectators.
h. Class IV facilities consist of elementary school and recreational facilities; and amateur league and high-school facilities without provision for spectators.

**Reason:** This proposal revises the lighting power density allowances to the best available values. “Best” means values that will lead to high energy-efficiency while still allowing high-quality lighting and sufficient light levels. We believe that the best source for these values is the process of the ASHRAE/IES 90.1 Lighting Subcommittee supported by PNNL/DOE. The IALD participates in the development of these values through our representation on the 90.1 Lighting Subcommittee and through the ANSI/ASHRAE/IES public review commenting process.
During this code cycle a detailed review and upgrade of the Space-by-space LPD models was performed by the 90.1 Lighting Subcommittee, rather than a simple update as in past code cycles. Because of this, we have even more confidence in these numbers.

The basis of the values in our proposal is Addendum BB to ASHRAE/IES Standard 90.1 Second Public Review Draft (November 2018). Addendum BB to Standard 90.1 is still a work-in-progress at the time of the submission of this code change proposal for IECC. We know that some of the LPD values will be revised before the publication of 90.1-2019. These values in our proposal are based on our involvement in the ongoing public comment process for Addendum BB and our understanding of the work of the 90.1 Lighting Subcommittee since the Addendum BB Second Public Review Draft was published last November. This proposal contains values that will more closely match the final values that we expect will be 90.1-2019, and are appropriate for inclusion in IECC-2021.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Complying with these new lighting power allowances will require more careful design but will not require the use of more expensive lighting fixtures than would be used otherwise.

e. Class I facilities consist of professional facilities; and semiprofessional, collegiate, or club facilities with seating for 5,000 or more spectators.
f. Class II facilities consist of collegiate and semiprofessional facilities with seating for fewer than 5,000 spectators; club facilities with seating for between 2,000 and 5,000 spectators; and amateur league and high-school facilities with seating for more than 2,000 spectators.
g. Class III facilities consist of club, amateur league and high-school facilities with seating for 2,000 or fewer spectators.
h. Class IV facilities consist of elementary school and recreational facilities; and amateur league and high-school facilities without provision for spectators.

**Reason:** Based on data gathered from industry partners and design professionals, practical LPD values have been determined. These LPD values are not just an update to existing models, but instead, include an extensive review and upgrade of those models. The work included:

- Evaluation of current Illuminating Engineering Society (IES) guidelines for lighting of commercial interiors (recommended footcandles, or illuminance, at the work plane) for all spaces. The ANSI/IES Recommended Practice (RP28-2016 for Seniors and the Low Vision Population) was used to inform both illuminance levels and fixture selection for space types in Facilities for the Visually Impaired.

- Expansion of categories used to assign room surface reflectance for each space type, based on actual usage,
not just design “rules of thumb.” Previously, most spaces were assumed to have ceiling surfaces of 70% reflectance, wall surfaces of 50% reflectance and floor surfaces of 20% reflectance (70/50/20). Through a consensus process, the developers of this proposal agreed to select the wall surface reflectance as the primary surface. Many spaces were reassigned to the category of 50/30/20 reflectance and some were reassigned to the 30/10/20 category.

- Update and expansion of the lighting fixture database. 100% of the fixtures are solid state (LED), using current off-the-shelf technology (fixture efficacy)

- Improvement of the high color quality data set for LED fixtures used in spaces that previously had incandescent, halogen or premium HID

- Standardization on a Light Loss Factor for LED of 0.85, not the End of Useful Life metric of 0.70

- Improvement of the wallwashing methodology for spaces where vertical surface illumination was deemed important

This methodology resulted in reductions in many LPDs, and increases in some. The overall reduction across all space types will result in energy savings of approximately 5% over IECC 2018.

Two space types were eliminated based on input from industry professionals: Audience Seating in a Convention Center and Corridor in a Manufacturing Facility. They were eliminated for similar reasons; the lighting specifier has to design for the entire space in a Convention Center or Manufacturing Facility. The seating area in a convention center is completely flexible based on user preference for each event. Similarly, corridors in Manufacturing Facilities are most often the circulation created between pieces of equipment or workbenches. Specifiers and users have allowances to use for Convention Centers and Manufacturing Facilities.

**Bibliography:** Addendum BB to ANSI/ASHRAE/IES Standard 90.1-2016, Energy Standard for Buildings Except Low-Rise Residential Buildings

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The Lighting Power Density values proposed in this code change proposal utilize off-the-shelf current LED technology and do not require additional or more expensive luminaires. The efficacy chosen for the models was based on the average of a fixture data set using luminaires from multiple manufacturers. Specifiers and users can find light fixtures that will allow the project to meet code at reasonable price points. Data gathered from industry partners indicates that product development is all directed at solid-state (LED) lighting with many traditional fixtures and lamp sources being discontinued.

Proposal # 5522

CE208-19
CE209-19

IECC: C405.4 (New), ASABE Chapter 6

Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute (ericM@newbuildings.org)

2018 International Energy Conservation Code

Add new text as follows:

C405.4 Lighting for plant growth and maintenance. Not less than 95 percent of the permanently installed luminaires used for plant growth and maintenance shall have a photon efficiency of not less than 1.6 μmol/J rated in accordance with ANSI/ASABE S640.

Add new standard(s) as follows:

S640-2017: Quantities and Units of Electromagnetic Radiation for Plants (Photosynthetic Organisms)

Reason: Indoor agriculture energy usage is projected to grow substantially over the next several years, driven in large part (but not entirely) by the legalization of medical and recreational marijuana. As more and more states legalize medical and recreational marijuana, this will become an increasing national issue. If the ICC does not take action on this, industry is likely to see a patchwork of different and even conflicting local solutions.

The Northwest Power and Conservation Council projects that indoor marijuana growing operations alone will add as much as 300 average megawatts by 2030. That is equivalent to 1.5% of total regional electricity
demand. Indoor agriculture operations not related to marijuana are expanding too. Indoor horticulture facilities can have EUIs that exceed even data centers.

![PACIFIC NORTHWEST CANNABIS ENERGY LOAD FORECAST](image)

The price of LEDs has fallen dramatically in the past few years and local food movements in cities are driving increased demand for fresh high-quality produce that is grown close to the point of consumption. More restaurants are interested in sourcing ingredients directly from the producer, and in dense urban areas a growing number of new indoor agriculture operations have begun to meet this demand. This potent combination of policy, technology, and market factors is driving a dramatic expansion in indoor agriculture. As written, the 2018 IECC leaves lighting in this growing energy load completely exempt from efficiency requirements.

This proposal removes the loophole by requiring lighting used for plant growth or maintenance to either meet an efficiency metric. The efficiency metric of 1.6 μmol/J (micromoles per Joule) was developed in collaboration with the American Society of Agricultural and Biological Engineers and was developed specifically for lighting used for plant growth. It measures the number of photons emitted from the fixture per Joule of energy consumed. Lighting Power Density was developed as a metric to evaluate the light usable for visual tasks relative to the power consumed. Likewise, this metric was developed specifically to measure the light usable for
plant growth relative to the power consumed. This metric is codified as an ANSI standard (ANSI/ASABE S640 – Quantities and Units of Electromagnetic Radiation for Plants (Photosynthetic Organisms)) and is already seeing wide adoption in the industry with over 84 products available that meet this requirement when surveyed in 2016. More information on the metric can be found in the ANSI Standard: ANSI/ASABE S640.

Using a typical High Pressure Sodium lamps (a common growing light) as the baseline, this requirement will result in 78% savings. That is a substantially lower lighting load and a reduction in the cooling load.

**Cost Impact:** The code change proposal will increase the cost of construction

The proposal could marginally add to the cost of construction. The cost of horticultural lighting fixtures is actually driven to a large extent by reflectors and ventilation needs (horticultural lighting is positioned very close to the plants and venting the heat is essential) and not just lighting technology. Therefore, fixture cost can very dramatically, from $25/fixture to almost $1000/fixture for High Pressure Sodium fixtures and from $75/fixture to well over $1000/fixture for LED. And advancements and expanding market share of LED lighting has narrowed the impact of lighting technology. Therefore, lighting that meets this requirement can be obtained for less than lighting that does not. The only projects that will see an increase in cost are those using the absolute cheapest lighting that does not meet the requirement.
2018 International Energy Conservation Code

Revise as follows:

C405.4.1 Total connected exterior building exterior lighting power. The total exterior connected lighting power shall be the total maximum rated wattage of all lighting that is powered through the energy service for the building, applications listed in Table C405.4.2(2) and Table C405.4.2(3).

Exception: Lighting used for the following applications shall not be included.

1. Lighting approved because of safety considerations.
2. Emergency lighting automatically off during normal business operation.
3. Exit signs.
4. Specialized signal, directional and marker lighting associated with transportation.
5. Advertising signage or directional signage.
6. Integral to equipment or instrumentation and installed by its manufacturer.
7. Theatrical purposes, including performance, stage, film production and video production.
8. Athletic playing areas.
10. Industrial production, material handling, transportation sites and associated storage areas.
11. Theme elements in theme/amusement parks.
12. Used to highlight features of art, public monuments, and the national flag.
13. Lighting for water features and swimming pools.
14. Lighting controlled from within dwelling units, where the lighting complies with Section R404.1.

C405.4.2 Exterior lighting power allowance. The total exterior lighting power allowance is the sum of the base site allowance plus the individual allowances for areas that are to be illuminated by lighting that is powered through the energy service for the building. Lighting power allowances are as specified in Table C405.4.2(2). The lighting zone for the building exterior is determined in accordance with Table C405.4.2(1) unless otherwise specified by the code official.

Reason: This proposal would increase the scope of outdoor lighting requirements to all commercial lighting applications in Table C405.4.2(2) and Table 405.4.2(3) regardless of whether the power to these outdoor lighting applications passes through a building’s service. Examples of outdoor lighting energy efficiency that is "falling between the cracks" of effective regulation include:

- parking lot lighting for malls where the service entrance is not associated with any building on the site.
- parking lot lighting not associated with any building, such as might be adjacent to ball fields, fairgrounds etc.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal will increase the scope of the current IECC lighting requirements to more applications but the stringency and cost are not being increased.
IECC: C405.4.2, C405.4.2.1

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com); Jack Bailey (jbailey@oneluxstudio.com)

2018 International Energy Conservation Code

Delete and substitute as follows:

C405.4.2 Exterior lighting power allowance. The total exterior lighting power allowance is the sum of the base site allowance plus the individual allowances for areas that are to be illuminated by lighting that is powered through the energy service for the building. Lighting power allowances are as specified in Table C405.4.2(2). The lighting zone for the building exterior is determined in accordance with Table C405.4.2(1) unless otherwise specified by the code official.

C405.4.2 Exterior lighting power allowance. The exterior lighting power allowance (watts) is calculated as follows:

1. Determine the Lighting Zone (LZ) for the building according to Table C405.4.2(1) unless otherwise specified by the code official.
2. For each exterior area that is to be illuminated by lighting that is powered through the energy service for the building, determine the applicable area type from Table C405.4.2(2). For area types not listed, select the area type that most closely represents the proposed use of the area.
3. Determine the total area or length of each area type and multiply by the value for the area type in Table C405.4(2) to determine the lighting power (Watts) allowed for each area type.
4. The total exterior lighting power allowance (Watts) is the sum of the base site allowance determined according to Table C405.4.2(2), plus the Watts from each area type.

Revise as follows:

C405.4.2.1 Additional exterior lighting power. Any increase in the Additional exterior lighting power allowance is limited to allowances are available for the specific lighting applications indicated listed in Table C405.4.2(3). The additional power allowances shall be used only for the luminaires that are serving these specific applications and shall not be used for to increase any other purpose lighting power allowance.

Reason: This proposal clarifies the calculation procedures for compliance with exterior lighting power requirements. Currently the code does not provide clear or complete direction. There is no change in stringency. This proposal makes this calculation procedure easier to understand and will increase the usability of the code. Codes which are usable are more likely to be complied with and are easier to enforce.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is a re-write to clarify code requirements.

Proposal # 4617
2018 International Energy Conservation Code

Revise as follows:

C405.8.1 Elevator cabs (Mandatory). For the luminaires in each elevator cab, not including signals and displays, the sum of the lumens divided by the sum of the watts shall be not less than 35 lumens per watt. Ventilation fans in elevators that do not have their own air-conditioning system shall not consume more than 0.33 watts/cfm at the maximum rated speed of the fan. Controls shall be provided that will de-energize ventilation fans and lighting systems when the elevator is stopped, unoccupied and with its doors closed for over 15 minutes.

C405.8.2 Escalators and moving walks (Mandatory). Escalators and moving walks shall comply with ASME A17.1/CSA B44 and shall have automatic controls configured to reduce speed to the minimum permitted speed in accordance with ASME A17.1/CSA B44 or applicable local code when not conveying passengers.

Exception: A variable voltage drive system that reduces operating voltage in response to light loading conditions is an alternative to the reduced speed function.

C405.8.2.1 Regenerative drive (Mandatory). An escalator designed either for one-way down operation only or for reversible operation shall have a variable frequency regenerative drive that supplies electrical energy to the building electrical system when the escalator is loaded with passengers whose combined weight exceeds 750 pounds (340 kg).

C405.9 Voltage drop in feeders and branch circuits (Mandatory). The total voltage drop across the combination of feeders and branch circuits shall not exceed 5 percent.

C407.2 Mandatory requirements. Compliance with this section requires compliance with Sections C402.5, C403.2, C403.3 through C403.3.2, C403.4 through C403.4.2.3, C403.5.5, C403.7, C403.8.1 through C403.8.4, C403.10.1 through C403.10.3, C403.11, C403.12, C404 and C405.1, C405.2, C405.4 through C405.9.

Reason: The provisions of C405.8.1, C405.8.2, and C405.9 are a combination of performance requirements and references to standards, with no associated performance metrics or values available to model or trade in the performance path. For this reason C405.8.1, C405.8.2, and C405.9 are mandatory. This is consistent with the parallel provisions of ASHRAE 90.1 10.4.3, 10.4.4, and 8.4.1, which are identified as ‘mandatory.’

Note that the SEHPCAC has a proposal to eliminate the use of the labels "prescriptive “and "mandatory" in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction
Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at:
http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx
(http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx)

Cost Impact: The code change proposal will increase the cost of construction
As commonly interpreted, these items are already considered mandatory, and therefor should have no impact on cost. However, it may increase the cost of construction for a subset of buildings designed to comply with Section C407 that do not include the specifications for vertical and horizontal transportation systems as included in Section C405.8 and C405.9.

Proposal # 4190

CE212-19
Proponent: Kevin Brinkman, representing National Elevator Industry, Inc. (klbrinkman@neii.org)

2018 International Energy Conservation Code
Revise as follows:

C405.8.2 Escalators and moving walks. Escalators and moving walks shall comply with ASME A17.1/CSA B44 and Where a traffic analysis indicates that an escalator or moving walk application will have sufficient periods with no riders while it is operating, it shall have automatic controls configured to that reduce speed to the minimum as permitted speed in accordance with ASME A17.1/CSA B44 or applicable local code when not conveying passengers.

Exception: A variable voltage drive system that reduces operating voltage in response to light loading conditions is an alternative to the reduced speed function.

C405.8.2.1 Regenerative drive. Power Recovery. An escalator designed either for one way down operation only or for reversible operation shall have a variable frequency regenerative drive that supplies electrical energy to the building electrical system when the escalator is loaded Where a traffic analysis indicates that an escalator application will have sufficient periods in the down direction with passengers whose combined weight exceeds 750 pounds (340 kg), the escalator shall be designed to recover, on average, more power than is consumed by the power recovery feature of its motor controller system.

Reason: The universal application of technology designed for energy efficiency improvement imposed by the current requirement may actually increase energy consumption in many applications. The proposed revision would require a traffic analysis to determine whether the technology would actually be beneficial or detrimental. The proposed language also uses more prescriptive language for the power recovery to allow designers and manufacturers to select the most energy efficient technology for the application.

C405.8.2: Depending on the escalator or moving walk application, varying speeds may actually increase energy usage. Each time the escalator or moving walk returns to the normal operating speed from its reduced speed condition, more energy is consumed to create the acceleration needed. In applications where the amount of time that there are no riders is very short, the energy consumed during the acceleration stage may actually exceed what is saved during the reduced speed segments. The traffic analysis can be used to calculate the anticipated savings, if any, to determine whether the technology should be applied and the return on investment.

C405.8.2.1: It should be noted that most, if not all, escalators are designed to be reversible, so the provision in the current edition would be applied to all escalators, including those that always run in the up direction. Depending on the escalator application, there may be only marginal gains in applying one technical solution over another and therefore no single technical solution should be prescribed for all escalators as stated in the current standard. The proposed language uses more prescriptive language for the power recovery to allow designers and manufacturers to select the most energy efficient technology for the application and ensure that if applied it actually recovers more power on average than the added feature would consume. [Note: some examples may include direct induction motor regeneration, variable frequency regeneration motor controller, or various combinations of the two.]

To further illustrate the deficiencies in the current language and support the need for an analysis to determine the best option for energy usage, three hypothetical scenarios are provided below with three configurations of motor controller-motor energy recovery arrangements. In each configuration, power recovery (regen power) back to the supply system can only be realized when the escalator is running in the down direction with a

ICC COMMITTEE ACTION HEARINGS :: April, 2019  CE564
sufficient load to overcome friction. (See sample motor controller configuration diagrams under Technical Backup).

**Electrical DATA**

Rise: 18’ (approx. 6m)

Power: 15Hp/11kW

Power factor (Pf) 0.75

Voltage: 480VAC

**Configuration 1** is an electro-mechanical motor controller with an AC induction motor that can feed direct power back to the power supply system when the escalator is running in the down direction with sufficient load.

**Configuration 2** is an electronic motor controller with no regeneration capability but can reduce escalator speed when there are no riders on it, and uses the AC motor to feed direct power back to the power supply system when the escalator is running in the down direction with sufficient load.

**Configuration 3** is an electronic motor controller with regeneration capability back to the power supply system when the escalator is running in the down direction with sufficient load driving an AC induction motor.

**A) Approximate additional energy consumption (kW/hr.) by the controller for the four types of motor controls considered (electro-mechanical is baseline):**

1. Electro-mechanical motor controller with AC induction motor ~ 0 kW

2. Electronic motor controller (VVVF) without regen and with AC induction motor ~ 0.285 kW

3. Electronic motor controller (VVVF Pf1 regen type) with AC induction motor ~ 0.430 kW

**B) Approximate energy saved (kW/hr.) at reduced speed for the three types of motor controls considered:**

1. Electro-mechanical motor controller with AC induction motor ~ 0 kW (reduced speed not possible)

2. Electronic motor controller (VVVF) without regen and with AC induction motor ~ 1.5 kW

3. Electronic motor controller (VVVF Pf1 regen type) with AC induction motor ~ 1,5 kW

**C) Approximate energy recovered (kW/hr) by the escalator for the three types of motor controls considered:**

1. Electro-mechanical motor controller with AC induction motor ~ 3 kW

2. Electronic motor controller (VVVF) without regen and with AC induction motor ~ 3 kW

3. Electronic motor controller (VVVF Pf1 regen type) with AC induction motor ~ 4 kW
Summary: From the three application scenarios below, it will be seen that the energy savings from each configuration very much depends upon the application and use of the escalator:

- The single dedicated down airport escalator in Scenario 1 with the VVVF Pf1 regenerative motor controller of Configuration 3 provides the best energy efficiency. This configuration is specified by the current standard.
- The single up escalator with a peak hour down direction in scenario 2 is better suited with the VVVF motor controller in Configuration 2 that can reduce the speed of the escalator when no riders are present but uses the AC motor to feed direct power back to the power supply system when the escalator is moving in the down direction with sufficient load.
- The heavily used bi-directional shopping mall escalators in Scenario 3 will consume more energy with the added speed reduction and power recovery features of Configuration 2 and 3 than they would by simply allowing the AC induction motor of Configuration 1 to recover direct energy from the induction motor whenever possible.

The NEII proposed code modifications address the application sensitivity in achieving energy recovery and savings by making the application of the conveyance a factor in selecting the best suited energy saving configuration.

Application Scenario 1

An airport is open 18 hours per day with a dedicated down escalator to baggage claim. When flights arrive, it is loaded with more than 75% capacity for 5 minutes for each flight and zero load the remainder of the time. One hundred and twenty arriving flights per day use this baggage claim escalator.

Escalators load during the 18 operating hours:

1. 0% load for 8 hours (=Total time where reduced speed can be applied)
2. > 0%, < 75% load for 0 hours
3. 75% load or more for 10 hours

Application Scenario 2
A subway station open 22 hour per day has one escalator for each platform. Typically, the escalator runs in the up direction most of the time and in the down direction during peak rush hour. Scenario for reduced power consumption and regen power is as follows:

### Escalators load during the 22 operating hours (20hrs up and 2hrs down):

1. 0% load for 10 hours up direction (Total time where reduced speed can be applied)

2. > 0%, < 75% load for 10 hours up direction

3. 75% load or more for 2 hours down direction

### Application Scenario 3

A busy outdoor mall is open 12 hours per day has two escalators. Typically, one of the escalators will be running up and the other in the down direction. Both escalators can run down and each may be used for that direction from time to time. Scenario for reduced power consumption and regen power is as follows:

### Escalators load during the 12 operating hours:

1. 0% load for 0 hours (Total time where reduced speed can be applied)

2. > 0%, < 75% load for 12 hours

3. 75% load or more for 0 hours

Technical backup.

Energy is utilized by escalators for the following:

1. to overcome friction,
2. transport the load, and
3. inertia (starting) (insignificant for configuration 1 minimum for the others)

Because of the angle of inclination, transport of the escalator load is the dominate energy consumption area of the system to move a load up the inclination. However, the converse is true that when the load is being transported in the down direction, energy can be produced by the overhauling of the drive motor from the downward moving load and returned to the power system.

In general, an AC induction motor used to drive an escalator will produce power when it is in overhauling in the down direction with sufficient passenger loading to overcome the friction in the system. AC induction motors may be applied with simple electro-mechanical or fully electronic motor controllers and still provide this capability. Other variations of motor types, such as permanent magnet motors and variable voltage variable frequency motor control are also possible, and may also provide an energy saving reduced speed feature in the application. However, the electronics required for the various technologies to provide these motor control functions also consumes energy and must be weighed against the possible energy saving under the application and use of the escalator.

It should also be pointed out that in certain applications, escalators and moving walks with a speed reduction feature are confronted with flows of traffic that can cause the escalator or moving walk to continually switch between full to reduced speed and back to full speed. With a high enough frequency, this switching between slow to full speed will consume more energy than saved by the feature because of the need to accelerate the mass to full speed each time.

Example configurations (basic diagrams)

Cost Impact: The code change proposal will decrease the cost of construction
The code change proposal will decrease the cost of construction because it would allow alternate designs to achieve energy conservation.
CE214-19

IECC: C405.9

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C405.9 Voltage drop in feeders and branch circuits. The total voltage drop across the combination of feeders, customer-owned service conductors, feeder conductors and branch circuits conductors shall not exceed 5 percent.

Reason: Revising this language will:
1. Increase energy efficiency
2. Reduce inconsistency and application confusion in compliance

The current requirement for voltage drop in feeder conductors does not include customer-owned service conductors. These are runs, owned by customers, from the utility service to the building main disconnect. These runs can be quite long which result in significant voltage drop and efficiency losses.

An editorial change adding the word “conductors” to feeder and branch circuits, provides greater clarity.

Cost Impact: The code change proposal will increase the cost of construction
The increased cost in construction would only apply when the service feeder conductors are customer-owned and only if they would not have been designed to the 5% voltage drop allowance of the present code. This should represent a small subset of building construction projects. Additionally, the cost effectiveness of this code change remains the same as for all other service conductors under the present provision. This is not adding to stringency of this requirement. It only expands the conditions where the requirement is applied and maintains the cost effectiveness, as has been the case for the current voltage drop requirement.

Proposal # 4445
CE215-19

IECC: C405.10 (New), C405.10.1 (New), C405.10.2 (New),
TABLE C405.10.2 (New), C405.10.2 (New), C405.10.4 (New), C405.10.5(New)

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association
(mar_williams@nema.org)

2018 International Energy Conservation Code

Add new text as follows:

C405.10 Energy Monitoring (Mandatory) New buildings with a gross conditioned floor area of 25,000 square feet or larger shall be equipped to measure, monitor, record and report energy consumption data in compliance with Section C406.10.1 through C406.10.5.

Exception: Individual tenant spaces are not required to comply with this section provided the space has its own utility services and meters and has less than 5,000 square feet of conditioned floor area.

C405.10.1 Electrical energy metering. For electrical energy, including all electrical energy supplied to the building and its associated site, including but limited to site lighting, parking, recreational facilities, and other areas that serve the building and its occupants, meters or other measurement devices shall be provided to collect energy consumption data for each end-use category required by Section C405.10.2.

C405.10.2 End-use metering categories. Meters or other approved measurement devices shall be provided to collect energy use data for each end-use category indicated in Table 405.10.2. Where multiple meters are used to measure any end-use category, the data acquisition system shall total all of the energy used by that category. Not more than 5 percent of the measured load for each of the end-use categories indicated in Table 405.10.2 shall be permitted to be from a load that is not within that category.

Exceptions:

1. HVAC and water heating equipment serving only an individual dwelling unit shall not require end-use metering.
2. End-use metering shall not be required for fire pumps, stairwell pressurization fans or any system that operates only during testing or emergency.
3. End-use metering shall not be required for an individual tenant space having a floor area not greater than 2,500 square feet where a dedicated source meter complying with Section C405.10.3 is provided.

</tbody>
</table>

**C405.10.3 Meters.** Meters or other measurement devices required by this section shall be configured to automatically communicate energy consumption data to the data acquisition system required by Section C405.10.4. Source meters shall be allowed to be any digital-type meter. Lighting, HVAC, or other building systems that can monitor their energy consumption shall be permitted instead of meters. Current sensors shall be permitted, provided that they have a tested accuracy of plus or minus 2 percent. Required metering systems and equipment shall have the capability to provide at least hourly data that is fully integrated into the data acquisition system and graphical energy report in accordance with Sections C405.10.4 and C405.10.5.

**C405.10.4 Data acquisition system** A data acquisition system shall have the capability to store the data from the required meters and other sensing devices for minimum of 36 months. The data acquisition system shall have the capability to store real-time energy consumption data and provide hourly, daily, monthly, and yearly logged data for each end-use category required by Section C405.10.2.

**C405.10.5 Graphical energy report** A permanent and readily accessible reporting mechanism shall be provided in the building that is accessible by building operation and management personnel. The reporting mechanism shall have the capability to graphically provide the energy consumption for each end-use category required by Section C405.10.2 at least every hour, day, month, and year for the previous 36 months.

**Reason:** The investment made for the infrastructure of a building to comply with the IECC is significant. The assumption that is currently made upon commissioning a facility is that energy efficiency measures will not degrade, or go out of calibration, over time and their energy consumption will not increase as time passes from the time they were commissioned. Such assumption is completely inaccurate and any payback assumed for energy efficient infrastructure investments will be lengthened, thereby reducing the ROI and increasing the payback period. The only means to retain the energy performance of a building is to continuously monitor energy consumption levels of various energy consuming systems and compare them to previous leavel. Monitorin sub-systems provides key indications when changes have been made or systems are not operating to specification, which increases energy consumption. Examples include, but are not limited to:

1. Increase energy consumption in HVAC system loads will point to failures in motors, drive systems, bearings, etc.

2. Degrading building envelope.

3. Configuration changes to the building that may drive increased energy consumption.

4. Increase of energy consumption from lighting loads may indicate changes in arrangement of the office space that resulted in reduced lighting driving the installation of more lighting above permitted energy code levels, failure of occupant sensors, inappropriate lighting schedules, lamps that need to be replaced or cleaned, etc.
5. Monitoring plug loads will indicate when computer equipment is left on during non-working hours and use of space heaters that compromise the efficiency of the facility due to set points on the HVAC system.

The requirements in this proposal save energy by continually monitoring and reporting actionable energy consumption data to building owners and operators. For large buildings, this data is further broken out by the major sub-systems (HVAC, lighting, process loads, and plus loads). There are well documented studies that demonstrates the energy savings from metering and monitoring systems. The 2013 version of ASHRAE Std. 90.1 and several state energy codes have recognized the benefits and require energy monitoring to support a continual high level of performance from the energy efficient investment.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The code change proposal “will” increase the cost of construction because it will require additional hardware, software and labor during installation. Providing specific cost would violate antitrust laws, however the following link to a report provided by the GSA demonstrates an example of cost and savings: https://www.gsa.gov/cdnstatic/Energy_Submetering_Finance_Paper_Knetwork_2012_11_269%28508%29.pdf
C405.10 Automatic Receptacle Control The following shall be automatically controlled:

1. At least 50% of all 125 V, 15 and 20-amp receptacles installed in enclosed offices, conference rooms, rooms used primarily for copy or print functions, breakrooms, classrooms, and individual workstations, including those installed in modular partitions and module office workstation systems.
2. At least 25% of branch circuit feeders installed for modular furniture not shown on the construction documents.
3. Either split controlled receptacles shall be provided, with the top receptacle controlled, or a controlled receptacle shall be located within 12 inches of each uncontrolled receptacle.

This control shall function on:

1. A scheduled basis using a time-of-day operated control device that turns receptacle power off at specific programmed times and can be programmed separately for each day of the week. The control device shall be configured to provide an independent schedule for each portion of the building of not more than 5000 ft² and not more than one floor. The occupant shall be able to manually override an area for not more than two hours. Any individual override switch shall control the receptacles of not more than 5000 ft².
2. An occupant sensor control that shall turn receptacles off within 20 minutes of all occupants leaving a space; or
3. An automated signal from another control or alarm system that shall turn receptacles off within 20 minutes after determining that the area is unoccupied.

All controlled receptacles shall be permanently marked in accordance with NFPA 70 and be uniformly distributed throughout the space. Plug-in devices shall not comply.

Exceptions: Receptacles for the following shall not require an automatic control device:

1. Receptacles specifically designated for equipment requiring continuous operation (24/day, 365 days/year).
2. Spaces where an automatic control would endanger the safety or security of the room or building occupants.
3. Within a single modular office workstation, non-controlled receptacles are permitted to be located more than 12 inches, but not more than 72 inches from the controlled receptacles serving that workstation.

Reason: This proposal will:
1. Increase building energy efficiency
2. Offer a well-studied, cost effective efficiency measure
3. Maintain building occupant's safe usability

4. Keep enforceability simple

5. Align with other energy efficiency codes, increasing design compliance.

**Cost Impact:** The code change proposal will increase the cost of construction.
Costs estimated to be $0.26/ft\(^2\) for small office implementation and $0.19/ft\(^2\) for large office. Payback estimated at 4.2 years for small office buildings (10,000sqft) and 2.4 years for large office buildings (100,000sqft). 2018 International Energy Conservation Code

Add new definition as follows:

ELECTRIC VEHICLE SUPPLY EQUIPMENT (EVSE). The conductors, including the ungrounded, grounded, and equipment grounding conductors, and the Electric Vehicle connectors, attachment plugs, and all other fittings, devices, power outlets, or apparatus installed specifically for the purpose of transferring energy between the premises wiring and the Electric Vehicle.

EV CAPABLE SPACE. Electrical panel capacity and space to support a minimum 40-ampere, 208/240-volt branch circuit for each EV parking space, and the installation of raceways, both underground and surface mounted, to support the EVSE.

EV READY SPACE. A designated parking space which is provided with one 40-ampere, 208/240-volt dedicated branch circuit for EVSE servicing Electric Vehicles. The circuit shall terminate in a suitable termination point such as a receptacle, junction box, or an EVSE, and be located in close proximity to the proposed location of the EV parking spaces.

Add new text as follows:

C405.10. Electric Vehicle (EV) charging for new construction. New construction shall facilitate future installation and use of Electric Vehicle Supply Equipment (EVSE) in accordance with the NFPA 70.

C405.10.1. New commercial buildings. EV Ready Spaces and EV Capable Spaces shall be provided in accordance with Table C405.10.1. Where the calculation of percent served results in a fractional parking space, it shall be shall rounded up to the next whole number. The service panel or sub panel circuit directory shall identify the spaces reserved to support EV charging as “EV Capable” or “EV Ready”. The raceway location shall be permanently and visibly marked as “EV Capable”.

EV READY SPACE AND EV CAPABLE SPACE REQUIREMENTS
C405.10.2. Identification. Construction documents shall indicate the raceway termination point and proposed location of future EV spaces and EV chargers. Construction documents shall also provide information on amperage of future EVSE, raceway methods, wiring schematics and electrical load calculations to verify that the electrical panel service capacity and electrical system, including any on-site distribution transformers, have sufficient capacity to simultaneously charge all EVs at all required EV spaces at the full rated amperage of the EVSE.
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

**ELECTRIC VEHICLE SUPPLY EQUIPMENT (EVSE).** The conductors, including the ungrounded, grounded, and equipment grounding conductors, and the Electric Vehicle connectors, attachment plugs, and all other fittings, devices, power outlets, or apparatus installed specifically for the purpose of transferring energy between the premises wiring and the Electric Vehicle.

**EV CAPABLE SPACE.** Electrical panel capacity and space to support a minimum 40-ampere, 208/240-volt branch circuit for each EV parking space, and the installation of raceways, both underground and surface mounted, to support the **EVSE**.

**EV READY SPACE.** A designated parking space which is provided with one 40-ampere, 208/240-volt dedicated branch circuit for **EVSE** servicing Electric Vehicles. The circuit shall terminate in a suitable termination point such as a receptacle, junction box, or an **EVSE**, and be located in close proximity to the proposed location of the EV parking spaces.

Add new text as follows:

**R404.2 (IRC N1104.2) Electric Vehicle (EV) charging for new construction.** New construction shall facilitate future installation and use of **Electric Vehicle Supply Equipment (EVSE)** in accordance with the National Electrical Code (NFPA 70).

**R404.2.1 (IRC N1104.2.1) One- to two-family dwellings and townhouses.** For each dwelling unit, provide at least one **EV Ready Space**. The branch circuit shall be identified as “EV Ready” in the service panel or subpanel directory, and the termination location shall be marked as “EV Ready”.
**Exception:** **EV Ready Spaces** are not required where no parking spaces are provided.

**R404.2.2 (IRC N1104.2.2) Multifamily dwellings (three or more units).** **EV Ready Spaces** and **EV Capable Spaces** shall be provided in accordance with Table R404.2.2. Where the calculation of percent served results in a fractional parking space, it shall round up to the next whole number. The service panel or subpanel circuit directory shall identify the spaces reserved to support EV charging as “EV Capable” or “EV Ready”. The raceway location shall be permanently and visibly marked as “EV Capable”.

**R404.2.3 (IRC N1104.2.3) Identification.** Construction documents shall indicate the raceway termination point and proposed location of future EV spaces and EV chargers. Construction documents shall also provide information on amperage of future EVSE, raceway methods, wiring schematics and electrical load calculations to verify that the electrical panel service capacity and electrical system, including any on-site distribution transformers, have sufficient capacity to simultaneously charge all EVs at all required EV spaces at the full rated amperage of the EVSE.

**Reason:** In the United States, electric vehicle (EV) sales increased by 80 percent from 2017 to 2018 (1). According to a November 2018 forecast from the Edison Electric Institute, the number of EVs on U.S. roads is projected to grow from 1 million vehicles at the end of 2018, to 18.7 million by 2030. To recharge these new EVs, the U.S. will need 9.6 million charge ports, a substantial portion of which will be installed in single and multi-family residential buildings (2).

![EV Charging Infrastructure by Location (2030)](image)

Figure 1. EV Charging Infrastructure in 2030 Based on EEI/IEI Forecast.

EVs provide significant economic benefits for consumers through fuel and maintenance cost savings, and have been identified as a key climate strategy to reduce GHG emissions from the U.S. transportation sector. The interest in EVs has grown alongside greater EV model availability and increased vehicle range. Every major auto manufacturer in the world has announced a plan to electrify a significant portion of their vehicle fleets over the next 3-5 years. Ford recently announced an $11 billion investment to reach their goal of 40 EV models by 2022 (3). The goal for GM: 20 EV models by 2023 (4); for VW: 27 EV models by 2022 (5); for Toyota: 10 BEVs by the early 2020’s (6); and similar goals for Volvo, Daimler, Nissan, BMW, and Fiat-Chrysler.
However, the lack of access to EV charging stations continues to be a critical barrier to EV adoption. In particular, there are significant logistical barriers for residents of multi-family dwellings to upgrade existing electrical infrastructure and install new EV charging stations.

A lack of pre-existing EV charging infrastructure, such as electrical panel capacity, raceways, and pre-wiring, can make the installation of a new charging station cost-prohibitive for a potential EV-owner. The installation of an EV charging station is made three to four times less expensive when the infrastructure is installed during the initial construction phase as opposed to retrofitting existing buildings to accommodate the new electrical equipment.

New residential buildings are constructed to last for decades, and so it is critical that EV charging infrastructure is incorporated at the pre-construction stage to ensure that new buildings can accommodate the charging needs of future EV-owners.

Bibliography:

Cost Impact: The code change proposal will increase the cost of construction
The code change proposal will increase the cost of initial construction, but provide long-term savings for EV owners through the avoided retrofit costs of installing EV charging infrastructure.

One- and two-family dwellings: additional costs include the price and labor associated with the installation of one 40-ampere, 208/240-volt dedicated branch circuit and a circuit terminating in a receptacle, junction box, or EVSE. The proposed code will allow current and future EV-owners to avoid the cost of electrical equipment upgrades, demolition, and permitting for future retrofits.

Multi-family residential (3 or more units): The chart below compares the cost of installing the necessary electrical infrastructure to support EV-Ready spaces (complete circuit) and an EV-Capable spaces (PEV-capable) at the time of new construction versus a building retrofit. In one example, the cost estimate to retrofit
an existing building with two EV-Capable spaces is $5,640, and $4,800 or 85 percent of that cost would be avoided if EV-Capable infrastructure was included during the initial construction of the parking lot. These additional retrofit costs typically include labor expenses for demolition, trenching and boring, balancing the circuits, and new permitting costs.

Why Adopt EV Infrastructure Building Codes?

Cost Savings Modeled for the City of Oakland

In April, 2018, the California Air Resources Board published a cost analysis for a proposed code change to increase the required percentage of EV-Capable spaces. (8)

“Avoided Retrofit Costs: Significant retrofit costs can be avoided by installing EV charging infrastructure in new construction. CARB staff reviewed multiple sources to obtain average retrofit costs of installing infrastructure to support Level 2 charging stations in existing buildings. An estimated $7,000 per parking space can be avoided with multiple installations of Level 2 charging stations. An estimated $8,000 per parking space can be avoided when an individual Level 2 charging station is installed. These retrofit costs do not include the cost of the electrical vehicle supply equipment (EVSE). Retrofit costs are focused on parking lot trenching, adding electrical service and/or panel upgrades. The 10 percent requirement would result in the installation of an additional 38,000 to 47,000 parking spaces with EV charging infrastructure beyond the current 3 percent requirement. If the proposed 10% requirement is not adopted, CARB staff assumed that every one of these parking spaces would need the basic EV charging infrastructure (raceway and panel capacity) to become EV Capable and support future installation of Level 2 charging stations. CARB staff estimates that the avoided retrofit costs range from $272 million to $386 million between 2020 and 2025.”

2018 International Energy Conservation Code

Revise as follows:

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency credit requirements. Buildings shall comply with one or more of the following:
1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.

New buildings shall achieve a total of 10 credits from Tables C406.1(1) through C406.1(5). Where a building contains multiple use groups, credits from each use group shall be weighted by floor area of each group to determine the weighted average building credit.

** C406.1

Table C406.1(5) Additional Energy Efficiency Credits for Other* Occupancies

* Other occupancy groups include all Groups except for Groups B, R, I, E, and M.

** for occupancy groups listed in C406.7.1

Revise as follows:

**C406.1.1 Tenant spaces.** Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, Where the entire building complies using credits from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the
entire building is in compliance with this section.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. 9) and Variable refrigerant flow systems shall exceed list in the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent, in accordance with Sections C406.2.1, C406.2, C406.2.3 or C406.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) and Variable refrigerant flow systems not listed in the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 shall be limited to 10 percent of the total building system capacity, capacity for heating equipment where selecting C406.2.1 or C406.2.3 and cooling equipment where selecting C406.2.2 or C406.2.4.

Add new text as follows:

C406.2.1 More efficient HVAC heating performance. Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

C406.2.2 More efficient HVAC cooling performance. Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

C406.2.3 High efficiency HVAC heating performance. Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

C406.2.4 High efficiency HVAC cooling performance. Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

Revise as follows:

C406.3 Reduced lighting power. Buildings shall comply with Section C406.3.1 or C406.3.2.

C406.3.1 Reduced lighting power 10 percent. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90 percent of the total lighting power allowance calculated in accordance with Section C405.3.2.

Add new text as follows:

C406.3.2 Reduced lighting power more than 15 percent. Where the total connected interior lighting power calculated in accordance with Section C405.3.1 is less than 85 percent of the total lighting power allowance calculated in accordance with Section C405.3.2, additional energy efficiency credits shall be determined based on Equation 4-12, rounded to the nearest whole number.

\[ AEEC_{LPA} = AEEC_{10} \times 10 \times (LPA - LPD) / LPA \] (Equation 4-12)

Where:

\[ AEEC_{LPA} = C406.3.2 \text{ additional energy efficiency credits} \]

\[ LPD = \text{total connected interior lighting power calculated in accordance with Section C405.3.1} \]
LPA = total lighting power allowance calculated in accordance with Section C405.3.2

AEEC_{10} = C406.3.1 credits from Tables C406.1(1) through C406.1(5)

Revise as follows:

C406.5 On-site renewable energy. Buildings shall comply with Section C406.5.1 or C406.5.2.

C406.5.1 Basic Renewable Credits. The total minimum ratings of on-site renewable energy systems shall be one of the following:

1. Not less than 4.71-0.86 Btu/h per square foot (5.4-2.7 W/m²) or 0.50-0.25 watts per square foot (5.4-2.7 W/m²) of conditioned floor area.
2. Not less than 3 percent of the annual energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Add new text as follows:

C406.5.2 Enhanced Renewable Credits. Where the total minimum ratings of on-site renewable energy systems exceeds the rating in C406.5.1(1), additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

\[ AEEC_{RRa} = AEEC_{2.5} \times RRa / RR_f \] (Equation 4-13)

Where:

\[ AEEC_{RRa} = C406.5.2 \text{ additional energy efficiency credits} \]

\[ RRa = \text{actual total minimum ratings of on-site renewable energy systems in Btu/h, watts per square foot or W/m}^2) \]

\[ RR_f = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) in Btu/h, watts per square foot or W/m}^2 \]

\[ AEEC_{2.5} = C406.5.1 \text{ credits from Tables C406.1(1) through C406.1(5)} \]

Revise as follows:

C406.7 Reduced energy use in service water heating. Buildings shall comply with Sections C406.7.1 and either C406.7.2, C406.7.3 or C406.7.4.

C406.7.1 Building type. To qualify for this credit, the building shall contain one of shall be of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following use groups.

Types to use this compliance method:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Group E: Schools with full-service kitchens or locker rooms with showers
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.
Load fraction - Recovered or renewable water heating

The building service water-heating system shall have one or more of the following that are sized to provide not less than 60–30 percent of the building’s annual hot water requirements, or sized to provide 100–70 percent of the building’s annual hot water requirements if the building shall otherwise be required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. On-site renewable energy water-heating systems.

Add new text as follows:

**C406.7.3 Efficient fossil fuel water heater.** The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95% Et or 0.95 EF. This option shall receive only half the listed credits for buildings required to comply with C404.2.1.

**C406.7.4 Heat pump water heater.** Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average EF of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

Reason: The C406 Option Packages was introduced into the IECC in 2012 as part of the prescriptive method to achieve an additional 4% energy savings over the prescriptive requirements of the code. The original proposal included three additional options (reduced lighting power density, increased HVAC efficiency and renewables). The 2018 IECC now has eight options to select from. In 2018, PNNL performed an analysis to determine the energy savings potential for each of the eight options and found significant savings differences.

**How does the proposed measure compare to what’s required in current codes?**

The current additional efficiency package options are all considered equal in the 2018 IECC, and any one item must be selected to comply with the extra efficiency provision. However, there is a great deal of variation in the energy savings, as shown in Figure 1.
To address this issue PNNL developed a points based option that provides equity across the efficiency measure options. The analysis is presented in their technical brief “Relative Credits for Extra Efficiency Measures”

C406 – Additional Efficiency Credits

**Technical Analysis**

The technical analysis was conducted as follows:

- Prototype models are used in the analysis. Their development, and associated climate locations, are described in detail in the quantitative determination[1] and are available for download.[2] Four building prototypes were used to capture the difference between building types:
  - Medium office
  - Primary School

![Variation in Building Cost Savings for Options](image-url)
– Mid-rise Apartment

– Stand Alone Retail

EnergyPlus™ was used to evaluate each measure in the four prototypes in all U.S. climate zones, except in cases where there is not a strong interaction with building HVAC systems, where standard engineering calculations were used. This applies to service hot water and renewable energy. Dedicated outdoor air systems (DOAS) savings were estimated rather than modeled, as discussed in the “Relative Credits for Extra Efficiency Measures”.

- Using average annual commercial energy prices, cost savings for each measure are calculated as a percentage of building total annual energy cost.

- The cost percentages are converted to credit points, with the goal of not being exactly equivalent, but to provide approximate relative equivalency between measures. One point is assigned for each 0.25% of building energy cost savings.

Extra efficiency measures save energy by reducing energy use directly or reducing the heating or cooling loads in the building, resulting in lower HVAC energy use. The measure would require different items to be added to construction, depending on the combination of credits selected. The requirements for each measure are discussed under the individual items.

Why is an energy efficiency credit assignment method superior to other approaches?

The extra efficiency credit approach allows for designer and builder flexibility. While it is slightly more complicated to select multiple items and add up points, in many cases credit would be given for measures that are often included in buildings. Furthermore, using points rather than “just pick one” puts the options on more of a level consideration and better accounts for the impact of climate.

The climate zone impact is fairly broad, especially for cooling efficiency and building envelope measures. The spread is also broad for lighting reduction and plug load controls, as the reduced heat load must be made up by the heating system in colder climates, while in warmer climates there is added savings in the cooling system. Assigning the points relative to building energy cost savings and climate zone will reward savings measures appropriate to the location of the building, and more fairly across measures.
The points resulting from averaging four typical C406 measures (10% HVAC, 10% LPA, Renewable and 85% UA) are shown as the last item on the right side of Figure 2. These four average around 10 points across climate zones, while lighting power allowance—a popular option selection—averages around 8 points across climate zones. Selecting 10 points or 2.5% savings of building energy cost as the target of a point-based system makes sense as being slightly ahead or roughly equal to the approach followed in the 2018 IECC.

What strategies are considered to minimize compliance burdens?

To achieve savings from a combination of multiple measures under the 2018 IECC, the only recourse is to follow the performance path that requires a building model. Having a simple table of points for measures in different building types and climate zones bypasses the need for full performance modeling, which can be expensive relative to savings for smaller buildings. The end result is a performance-based approach that can be applied with the simplicity of a prescriptive approach.

Are there existing codes and standards that take a similar approach?

The outlined approach is based on the structure currently employed in the IECC for commercial buildings. It just
shifts from a “pick one” approach to one that selects adequate measures from the options to meet a required point level. It is also similar to packages of measures that have been utilized in both residential and commercial energy codes, particularly in the Pacific Northwest. The Washington code has successfully used such a structure to balance energy performance, design flexibility, and evolving technologies.

The existing measures were modified to better fit within the points option and to provide more flexibility.

**More efficient HVAC heating performance** (C406.2) There has been industry feedback that it is difficult to comply with the 10% increase in efficiency for the More Efficient HVAC Option because both the heating and cooling equipment must comply. The points option allows either heating or cooling or both to comply. This measure would be modified to provide separate credits for the following:

– Medium efficiency HVAC heating performance (C406.2.1) is a 5% improvement in efficiency over the existing minimum requirement.

– Medium efficiency HVAC cooling performance (C406.2.2) is a 5% improvement in efficiency over the existing minimum requirement.

– High Efficiency HVAC heating performance (C406.2.3) is a 10% improvement in efficiency over the existing minimum requirement.

– High Efficiency HVAC cooling performance (C406.2.4) is a 10% improvement in efficiency over the existing minimum requirement.

Note: If equipment efficiency tables for VRF or other items are added by another proposal, then remove the reference to the ASHRAE 90.1 tables and adjust the table number reference range to include all HVAC equipment tables.

– **C406.3 Reduced lighting power.** The proposal keeps the 10% reduced lighting power allowance threshold and adds a threshold of 15%. Lighting designers that want to design to lower LPD levels can also use the calculation (Equation 4-12) to achieve more points giving them more flexibility.

– **C406.5 On-site renewable energy.** The onsite renewable energy credit has been modified to allow for additional credit from increased system size over the base level requirement for this credit.

– **C406.7.1 Reduced energy use in service water heating.** The water heating option allows for credit for high efficiency gas and electric water heaters in addition to heat recovery.

Hart R and Y Xie. 2014. *End-Use Opportunity Analysis from Progress Indicator Results for ASHRAE Standard 90.1-2013.* PNNL-24043, Pacific Northwest National Laboratory, Richland, WA.
Cost Impact

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The current proposal does not require more investment, but rather expands existing options permitted under the 2018 IECC. The intention is to assess relative savings equity amongst current options, and identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as several of the evaluated options are included in current code. In some cases, costs may be reduced, as the outlined approach provides partial credit for selected items as well as credit for items that may have previously been included in the building design without credit. Costs, and cost effectiveness, are not evaluated for individual measures due to the vast number of potential combinations amongst building types, climates, and selected options. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.
CE219-19

IECC: C406.1

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code

Revise as follows:

C406.1 Requirements. Buildings shall comply with one or two or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

Reason: Section C406.1 establishes a set of additional efficiency measure options above base code requirements. The present code requires compliance with only one measure, yet the list of efficiency options has continued to grown without adding any efficiency to buildings. This proposal would modify the requirement so buildings would comply with two packages instead of just one to increase the energy efficiency of buildings.

Cost Impact: The code change proposal will increase the cost of construction. The impact would be the cost of the added measure which increases the energy efficiency of the building.
CE220-19

IECC: C406.1

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

C406.1 Requirements. Buildings shall comply with one or two or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

Reason: The purpose of this code change proposal is to improve the efficiency of the prescriptive compliance path by requiring the selection of two additional efficiency package options instead of only one. Section C406 was adopted in the 2012 IECC not only as an immediate efficiency improvement, but also as a means of facilitating code improvements in the future. As new technologies become available, the package options can be updated or the list of options can be expanded (as it was in the 2018 IECC) to provide more flexibility for code users. As additional efficiency is needed, the number of required options can be increased. Several states have adopted a package- or points-based approach similar to Section C406, and as more efficiency is needed, the number of options (or points) has been increased. We note that this proposal deals only with the prescriptive path, and that a separate proposal will address needed efficiency improvements in the performance path.

Cost Impact: The code change proposal will increase the cost of construction. The proposal requires additional efficiency measures to be installed in the building which will increase costs. However, we expect that design professionals and builders will select the package options that are the most cost-effective and the easiest to implement into specific designs.
Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute
(srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

**C406.2 More efficient HVAC equipment performance.** Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. *Variable refrigerant flow systems* shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent. Equipment* Building designers or owners using equipment* not listed in Tables C403.3.2(1) through C403.3.2(7.9) shall be limited to 10 percent of the total building system capacity. Provide documentation of equivalent energy efficiency performance to the satisfaction of the code official.

**Reason:** There are numerous problems with the current language that need to be fixed. This proposal improves the language in this section and provides more high-efficiency options.

1) VRF system limits

Under the current language, high-efficiency VRF systems are allowed to be used, but since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity.

2) Cooling Tower limits

Under the current language, cooling towers are shown in Table C403.2.3(8). Since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity. So a building could have a 500-ton water chiller system, but would only be allowed to install a 50-ton cooling tower. This is not technically feasible.

3) Computer Room AC limits

Under the current language, computer room AC units are shown in Table C403.2.3(9). Since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity. So if a building with a data center has 500 tons of cooling needed, with 250 tons needed for the data center, under the current language, you are only allowed to have 50 tons of computer room AC systems. Again, this is not feasible.

4) Limits on other high-efficiency HVAC equipment that is not listed in tables

Under the current language and tables in the IECC, many types of high-efficiency technologies are limited by the current language. The following is a partial list of technologies that are restricted by the current arbitrary 10% limit:

- Chilled Beam Systems
- Radiant Systems
- DX-DOAS units, without energy recovery
- DX-DOAS units, with energy recovery
- Vapor Compression Based Indoor Pool Dehumidifiers
- Floor-mounted computer room AC units (not listed in current tables)
- Ceiling-mounted computer room AC units (not listed in current tables)
- Combined space heating / water heating systems
- Heat Pump and Heat Reclaim Chiller Packages

Building owners and designers should be allowed to use other high-efficiency equipment to meet the criteria for additional HVAC energy efficiency without having to go to a full performance path option. This proposal allows the use of advanced technologies to improve the efficiency of the HVAC equipment (and the building) with the condition that proof must be provided to show energy savings.

**Cost Impact:** The code change proposal will increase the cost of construction
As an additional efficiency option allowing more technologies to be used, the impact on construction costs will depend on the technology that is chosen. To be conservative, it is assumed that the newer high-efficiency technologies have higher costs since they may not have achieved economies of scope and/or scale.

Proposal # 4707

CE221-19
Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute
(srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C406.2 More efficient HVAC equipment performance. Equipment with a rated heating or cooling capacity of less than 300,000 Btu/hour (87.9 kW) shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Equipment with a rated heating or cooling capacity of 300,000 Btu/hour (87.9 kW) or greater shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 5 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 5 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity.

Reason: New federal energy efficiency standards and new provisions in ASHRAE 90.1 continue to increase the minimum energy efficiency of many HVAC products. For an increasing number of products, especially in the larger sizes, the difference in energy efficiency between the required baseline models and the higher efficiency models is less than 10%. To provide options for buildings with larger equipment, this proposal requires smaller commercial equipment to increase efficiency by 10%, while larger equipment has to increase efficiency by 5%. For both heating and cooling systems, 300,000 Btu/hour (or 25 tons of cooling capacity) is a reasonable "break point" for additional efficiency requirements.

Cost Impact: The code change proposal will decrease the cost of construction. For larger buildings with larger HVAC equipment, this proposal makes the requirement more reasonable and achievable. For buildings using smaller HVAC equipment, this proposal will have no impact on the construction costs, as the requirement for smaller equipment is not changed.
CE223-19

IECC: C406.2

**Proponent:** Charles Foster, Self, representing self (cfoster20187@yahoo.com)

**2018 International Energy Conservation Code**

Revise as follows:

**C406.2 More efficient HVAC equipment performance.** Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity.

**Reason:** Under the current language, high-efficiency VRF systems are allowed to be used, but since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity.

2) Cooling Tower limits

Under the current language, cooling towers are shown in Table C403.2.3(8). Since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity. So a building could have a 500-ton water chiller system, but would only be allowed to install a 50-ton cooling tower. This is not technically feasible.

3) Computer Room AC limits

Under the current language, computer room AC units are shown in Table C403.2.3(9). Since they are not listed in Tables C403.2.3(1) through C403.2.3(7), they are limited to 10% of the building system capacity. So if a building with a data center has 500 tons of cooling needed, with 250 tons needed for the data center, under the current language, you are only allowed to have 50 tons of computer room AC systems. Again, this is not feasible.

4) Limits on other high-efficiency HVAC equipment that is not listed in tables

Under the current language and tables in the IECC, many types of high-efficiency technologies are limited by the current language. The following is a partial list of technologies that are restricted by the current arbitrary 10% limit:

- Chilled Beam Systems
- Radiant Systems
- DX-DOAS units, without energy recovery
- DX-DOAS units, with energy recovery
- Vapor Compression Based Indoor Pool Dehumidifiers
- Floor-mounted computer room AC units (not listed in current tables)
- Ceiling-mounted computer room AC units (not listed in current tables)
- Combined space heating / water heating systems
- Heat Pump and Heat Reclaim Chiller Packages

Building owners and designers should be allowed to use other high-efficiency equipment to meet the criteria for additional HVAC energy efficiency without having to go to a full performance path option. This proposal allows the use of advanced technologies to improve the efficiency of the HVAC equipment (and the building) with the condition that proof must be provided to show energy savings.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal would add flexibility which typically leads to lower costs. On the other hand, it could also lead to higher costs if owners chose to install higher efficiency equipment.
IECC: C406.2, TABLE C406.2 (New)

Proponent: Mark Lessans, Ingersoll Rand, representing Ingersoll Rand (mark.lessans@irco.com)

2018 International Energy Conservation Code

Revise as follows:

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent following requirements, as applicable, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent.

1. Package unitary air-cooled systems with cooling capacity greater than 65,000 Btu/h shall meet or exceed the applicable efficiency requirements listed in Table C406.2, or shall exceed the mandatory federal minimum efficiency requirements for IEER by not less than 10 percent, whichever is greater.
2. All other electrically operated unitary air conditioners and heat pumps with cooling capacity less than 760,000 Btu/h shall exceed the mandatory federal minimum efficiency requirements by not less than 10 percent.
3. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by not less than 10 percent.
4. All other systems shall exceed the applicable minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by not less than 10 percent. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity.

**Reason:** The purpose of this code change proposal is to ensure that next-generation commercial unitary air conditioners and heat pumps - those which are high-efficiency by future standards - are effectively promoted by Section C406.2 of the IECC. In doing so, this proposal will better align the energy code with DOE appliance and equipment standards, above-code programs, and manufacturer plans to improve their product offerings in response to them.

As written, C406.2 requires that all minimum efficiency requirements listed in the equipment efficiency tables of Section C403 be exceeded 10 percent. This requirement is appropriate for new buildings which utilize multiple equipment types for space conditioning, as well as for equipment that has multiple performance compliance paths. However, for package air-cooled unitary systems, conventionally referred to as rooftop units (RTUs), there are typically three different efficiency metrics listed in the equipment efficiency tables, all of which must be met. Exceeding these efficiencies proportionally does not make sense given updated standards and the capabilities of RTUs, and creates conflicting as well as commercially unattainable requirements.

This proposal solves this issue for package RTUs by focusing their requirements in C406.2 predominantly on cooling efficiency as defined by IEER, as this equipment operates primarily in cooling mode, even in cold climates. Additionally, IEER is the metric used by DOE for federal appliance standards covering this equipment. This proposal aligns efficiency requirements for commercial unitary air conditioners with those in the Consortium for Energy Efficiency (CEE) Advanced Tier specification, which took effect on January 1, 2019. CEE does not develop an Advanced Tier specification for commercial package heat pumps, so improvements proportionally similar are used in this proposal.

If approved, this proposal would raise IEER for package air-cooled unitary systems by roughly 25-40% above the requirements of Section C403, as well as roughly 10-20% above the efficiencies required by updated DOE appliance standards that take effect in 2023. Additionally, this proposal creates a “backstop” of 10% above federal appliance standards, so that the intent of Section C406.2 is met if DOE standards for this equipment is updated prior to revisions to Table C406.2. All other efficiency metrics governing RTUs will remain in place, as the equipment still must comply with all requirements of Section C403.

This code change is necessary to avoid conflicting requirements between EER and IEER, as well as commercially unattainable requirements for AFUE. Regarding EER (full-load performance) and IEER (blended part- and full-load performance), optimizing for one performance condition will yield sub-optimal performance at
another. While new products may improve both EER and IEER, one can only be improved incrementally at the expense of the other, and therefore requiring both to improve proportionally is not appropriate. Regarding AFUE, the requirements placed on furnaces and gas heating elements by C406.2 requires moving to a condensing technology, which is not commercially available in RTUs outside of highly niche applications. The product availability gap is related to condensate disposal; in rooftop applications there is no industry-accepted practice to dispose of condensing furnace condensate discharge, and inappropriate applications will lead to roof damage.

This code change proposal makes significant improvements to package air-cooled unitary system cooling efficiencies, and removes conflicting requirements that would prevent premium efficiency, next-generation equipment from being used in new construction. It maintains the intent of Section C406, while also keeping C406.2 relevant given changes to appliance standards and industry innovation since its original inclusion in the 2012 IECC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This is an editorial change only.
CE225-19

IECC: C406.2, TABLE C406.2 (New)

Proponent: Mark Lessans, Ingersoll Rand, representing Ingersoll Rand (mark.lessans@irco.com)

2018 International Energy Conservation Code

Revise as follows:

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity.

Exception: Electrically operated unitary and applied heat pumps that do not utilize electric resistance heating elements and utilize a gas-fired furnace for supplemental heating shall comply with the minimum efficiency requirements in Table C406.2, in addition to the requirements of Section C403.

Reason: For mechanical equipment to comply with Section C406.2 of the 2018 IECC, it must exceed by 10 percent the efficiencies listed in Tables C403.3.2(1) through C403.3.2(7), which require that gas-fired commercial warm air furnaces have an efficiency rating of at least 88 AFUE. However, in order for a furnace to meet this efficiency level, it must utilize a condensing technology, and in rooftop applications it is difficult to safely and effectively dispose of furnace condensate. By contrast, residential condensing furnaces typically dispose of condensate through a side wall of a home. As a result, condensing furnaces are niche, non-commercialized products in commercial applications, which severely limits the ability to use a furnace when complying with Section C406.2. The only realistic option for small commercial buildings with rooftop units is to use heat pumps which meet the efficiency requirements of Section C406.2, but even at these improved performance ratings, it does not make sense to forego the use of warm air furnaces in cold climates. The proposed code change will remove this barrier for dual fuel commercial rooftop units – packaged units which contain both a heat pump and a furnace for heating. In these systems, the heat pump is the primary source of heating, but when the outdoor ambient temperature is too low for the heat pump to operate...
effectively, the compressor disengages, and rather than relying on an electric resistance source, a natural gas furnace provides supplementary heating. This approach allows the rooftop unit to utilize a heat pump when it is efficient to do so, such as during shoulder seasons and mild winter days, and switch to a natural gas furnace at very low outdoor temperatures when the heat pump cannot perform efficiently, if at all. The result is a mechanical system that can be optimized for energy efficiency and lower operating costs, as well as for effective electric demand management without loss of heating utility.

This proposed code change is necessary to fully enable buildings in cold climates to benefit from the optimized utilization of both a heat pump and furnace to provide heating. Dual fuel commercial rooftop units are available from multiple equipment manufacturers in 3-10 ton (36,000-120,000 Btu/h) capacities, and much of the small commercial market segment served by these units uses the prescriptive path to comply with the energy code. This proposed code change increases the heat pump performance requirements beyond 10 percent, as would otherwise be required by C406.2, to make up for the use of a standard efficiency furnace to ensure the intent of this provision is met. As a result, the prescriptive path in the IECC will enable improved HVAC performance while maintaining comfort and cost-effectiveness – the intent of Section C406.2.

Because this change is part of an optional path, designers will be able to select a system that is optimized for a particular building design in order to maximize the energy-savings benefit. The requirement for additional efficiency measures is intended to provide flexibility in design with optimized costs; including the dual fuel heat pump option brings another technology to the table. It does not replace other options, it simply provides greater opportunity for efficient HVAC system selections – and energy efficiency.

The only reasonable alternative to this code change proposal is to maintain the status quo requirements in Section C406.2 of the IECC, which does little to recognize the energy efficiency benefit of dual fuel rooftop units. As written, C406.2 directs the building designer to select either a high efficiency heat pump or high efficiency furnace, both of which have their own technical limitations:

- Heat pump coefficient of performance (COP) declines as outdoor ambient temperatures get colder. At very low ambient temperatures, the heat pump compressor will completely disengage, and instead rely on a resistance heating element, which results in a COP < 1.0.
- Furnaces complying with C406.2 must have an annual fuel utilization efficiency (AFUE) ≥ 88, which requires moving to a condensing technology not commercially available in rooftop units.

Dual fuel RTUs solve these limitations by operating in heat pump heating mode when it is efficient to do so, and furnace heating mode when the heat pump cannot run efficiently. In many buildings, this will yield improved source efficiency, significantly lower energy costs, and lower combined emissions when compared to any other practical alternative.

Cost Impact: The code change proposal will decrease the cost of construction.

The proposed code change will decrease construction costs by providing additional options for equipment to comply with Section C406.2 and allowing the designer to select the optimal solution. It will also decrease utility costs for building owners and occupants by utilizing the most efficient heating source for a given outdoor ambient temperature, and has the potential to decrease utility costs further by enabling more effective demand response during peak electricity periods.

Proposal # 4503
SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional efficiency requirements. Buildings shall comply where new buildings shall achieve a total of 10 credits from Tables C406.1(1) through C406.1(5) where the table is selected based on the use group of the building. Where a building contains multiple use groups, credits from each use group shall be weighted by floor area of each group to determine the weighted average building credit. Credits may also be calculated in accordance with the relevant subsection of C406. Credits from the tables or calculation shall be achieved where a building complies with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

a. Other occupancy groups include all Groups except for Groups B, R, I, E, and M.

b. For occupancy groups listed in C406.7.1.
C406.1.1 Tenant spaces. Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, where the entire building complies using credits from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance; this section.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the listed in the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent in accordance with Sections C406.2.1, C406.2.2, C406.2.3 or C406.2.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) shall be limited to 10 percent of the total building system capacity for heating equipment where selecting C406.2.1 or C406.2.3 and cooling equipment where selecting C406.2.2 or C406.2.4.

Add new text as follows:

C406.2.1 Five percent heating efficiency improvement Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

C406.2.2 Five percent cooling efficiency improvement Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

C406.2.3 Ten percent heating efficiency improvement Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

C406.2.4 Ten percent cooling efficiency improvement Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

Revise as follows:

C406.3 Reduced lighting power. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90 percent of the total lighting power allowance calculated in accordance with Section C405.3.2. Buildings shall comply with Section C406.3.1 or C406.3.2 and dwelling units and sleeping units within the building shall comply with C406.3.3.

C406.3 C406.3.1 Reduced lighting power, power by more than 10 percent. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90 percent of the total lighting power allowance calculated in accordance with Section C405.3.2.

Add new text as follows:

C406.2.3 Reduced lighting power by more than 15 percent. Where the total connected interior lighting power calculated in accordance with Section C405.3.1 is less than 85 percent of the total lighting power allowance calculated in accordance with Section C405.3.2, additional energy efficiency credits shall be determined based on Equation 4-12, rounded to the nearest whole number.

\[ AEEC_{IP} = AEEC_{10} \times 10 \times (LPA - LPD) / LPA \] (Equation 4-12)
Where:

\[ \text{AE\textit{E ECC}_L P_4} = \text{C406.3.2 additional energy efficiency credits} \]

\[ \text{LPD} = \text{total connected interior lighting power calculated in accordance with Section C405.3.1} \]

\[ \text{LPA} = \text{total lighting power allowance calculated in accordance with Section C405.3.2} \]

\[ \text{AE\textit{E ECC}_10} = \text{C406.3.1 credits from Tables C406.1(1) through C406.1(5)} \]

C406.3.3 Lamp efficacy Not less than 95 percent of the interior lighting power (watts) from lamps in permanently installed light fixtures in dwelling units and sleeping units shall be provided by lamps with a minimum efficacy of 65 lumens per watt.

C406.5 On-site renewable energy. Buildings shall comply with Section C406.5.1 or C406.5.2

C406.5.1 On-site renewable energy. Basic Renewable Credits The total minimum ratings of on-site renewable energy systems not including systems used for credits under Section C406.7.2 shall be one of the following:

1. Not less than 1.71 \(0.86\) Btu/h per square foot (5.4 \(2.7\) W/m\(^2\)) or 0.50 \(0.25\) watts per square foot (5.4 \(2.7\) W/m\(^2\)) of conditioned floor area.
2. Not less than \(3\) percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Add new text as follows:

C406.5.2 Enhanced Renewable Credit Where the total minimum ratings of on-site renewable energy systems exceeds the rating in C406.5.1(1), additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

\[ \text{AE\textit{E ECC}_{RRa}} = \text{AE\textit{E ECC}_{2.5}} \times \frac{\text{RRa}}{\text{RR1}} \text{ (Equation 4-13)} \]

Where:

\[ \text{AE\textit{E ECC}_{RRa}} = \text{C406.5.2 additional energy efficiency credits} \]

\[ \text{RRa} = \text{actual total minimum ratings of on-site renewable energy systems (in Btu/h, watts per square foot or W/m}^2) \]

\[ \text{RR1} = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) (in Btu/h, watts per square foot or W/m}^2) \]

\[ \text{AE\textit{E ECC}_{2.5}} = \text{C406.5.1 credits from Tables C406.1(1) through C406.1(5)} \]

C406.7 Reduced energy use in service water heating. Buildings shall comply with Sections C406.7.1 and either C406.7.2, C406.7.3 or C406.7.4, be of the following types to use this compliance method:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

C406.7 C406.7.1 Reduced energy use in service water heating. Building Type Buildings shall be. To qualify for this credit, the building shall contain one of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following types to use this compliance method groups:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Group E: Schools with full-service kitchens or locker rooms with showers
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

C406.7.2 Load fraction. Recovered or renewable water heating The building service water-heating system shall have one or more of the following that are sized to provide not less than 60-30 percent of the building’s annual hot water requirements, or sized to provide 100-70 percent of the building’s annual hot water requirements if the building shall otherwise is required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. On-site renewable energy water-heating systems.

Add new text as follows:

C406.7.3 Efficient fossil fuel water heater The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95% Et or 0.95 EF. This option shall receive only half the listed credits for buildings required to comply with C404.2.1.

C406.7.4 Heat pump water heater Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average EF of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

Reason: C406 Credits for Dwelling Lighting Efficacy
This proposal builds on top of a proposal that assigns energy efficiency credits to each option in Section C406 (CE218-19). For clarity, that entire base proposal is included here with additional provisions and table row additions that provide additional energy efficiency credits when:

- The lighting power density is reduced by more than 15% below the required lighting power allowance. For this option the 10% reduction credits in Section C406.3.1 are multiplied by the ratio of actual lighting power density reduction to lighting power allowance
- The efficacy of lamps installed in sleeping and dwelling units is higher than required in the residential section of the code and appropriate credits for that improvement are added as new lines in the credit tables.

The provision expands the available credits for more than 10% lighting power reduction where the lighting
power density is reduced by more than 15%.

Currently, a 10% lighting reduction in lighting power allowance is required for this extra efficiency option; however dwelling units and sleeping units can follow the residential lighting efficacy requirements. As a result, the applicability of option C406.3 is unclear for multi-family buildings. This measure would make clear the 10% lighting reduction applies to areas in a multi-family building that are not dwelling units and sleeping units and would apply a higher efficacy rating in the dwelling and sleeping units than is required in the residential lighting requirements.

To achieve this extra efficiency credit, this measure would increase the efficacy requirement for lamps in permanently installed fixtures and make them more in line with lamps available today.

This measure provides more clarity for multi-family buildings for the extra efficiency credit. Lamps meeting the higher efficacy requirement are readily available and appropriate for an optional credit.

Bibliography:

www.1000bulbs.com for lamp prices

Cost Impact: The code change proposal will not increase or decrease the cost of construction
To achieve the lighting credit in multi-family buildings, this proposal will require higher efficicacy lamps in dwelling units and sleeping units. However, these lamps are readily available in the market place, and checking internet sources has found them to actually be less costly than the slightly lower efficacy alternative required under the residential code. LED lamps were found to be about 85% the cost of similar output compact fluorescent lamps. If compared to incandescent lamps, there may be a cost increase, but the life of either the CFL or LED lamps is 10 or 15 times as long, resulting in a much lower cost per year of service.

Further, the current proposal does not require more investment, but rather expands existing options permitted under the 2018 IECC. In fact, credit is now given to lighting reductions greater than 10%. The intention is to assess relative savings equity amongst current options, and identify additional options to increase flexibility and more effectively utilize new technologies and construction practices.

There is not expected to be an increased cost, as several of the evaluated options are included in current code. In some cases, costs may be reduced, as the outlined approach provides partial credit for selected items as well as credit for items that may have previously been included in the building design without credit. Costs, and cost effectiveness, are not evaluated for individual measures due to the vast number of potential combinations amongst building types, climates, and selected options. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.

Proposal # 4981

CE226-19
Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C406.3 Reduced lighting power. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90-95 percent of the total lighting power allowance calculated in accordance with Section C405.3.2.

Reason: In another proposal, the LPD values being proposed for ASHRAE 90.1-2019 (Addendum bb) are proposed for the IECC. This addendum significantly lowers the LPD values in many spaces, due to the following:
- Going from 77% LED / 23% non-LED fixtures in 90.1-2016 modeling to 100% LED fixtures for 90.1-2019.
- Significantly increasing the average baseline efficacy to 110 Lumens / Watt.
- Reducing the target footcandles in common space types for 90.1-2019 compared to 90.1-2016.

(source: ASHRAE Lighting Subcommittee Presentation, August 2018)

Assuming that the other proposal passes, the "floor" of lighting efficiency will have increased significantly, leaving much less "head room" for higher efficiency options.

This proposal make this efficiency option more achievable and more realistic, based on the updated LPD values that are likely to be adopted in the next version of the IECC.

Cost Impact: The code change proposal will decrease the cost of construction
This proposal makes this efficiency option more realistic and achievable with available technologies, and will reduce the cost of this option.

Proposal # 4861
2018 International Energy Conservation Code

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency requirements. Buildings New buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

Revise as follows:

C406.3 Reduced lighting power. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90 percent of the total lighting power allowance calculated in accordance with Section C405.3.2. Buildings shall comply with Section C406.3.1 and dwelling units and sleeping units within the building shall comply with C406.3.2.

Add new text as follows:

C406.3.1 Reduce lighting power by more than 10 percent. The total connected interior lighting power calculated in accordance with Section C405.3.1 shall be less than 90 percent of the total lighting power allowance calculated in accordance with Section C405.3.2.

C406.3.2 Lamp Efficacy Not less than 95 percent of the interior lighting power (watts) from lamps in permanently installed light fixtures in dwelling units and sleeping units shall be provided by lamps with a minimum efficacy of 65 lumens per watt.

Reason: C406 add Dwelling Lighting Efficacy
Currently, a 10% lighting reduction in lighting power allowance is required for this extra efficiency option; however the lighting power concept does not apply to dwelling units and sleeping units, which can follow the residential lighting efficacy requirements. As a result, the applicability of option C406.3 is unclear for multi-family buildings. This measure would make clear the 10% lighting reduction applies to areas in a multi-family building that are not dwelling units and sleeping units and would apply a higher efficacy rating in the dwelling and sleeping units than is required in the residential lighting requirements.

For buildings with residential occupancy, this measure would increase the efficacy requirement for lamps in permanently installed fixtures and make them more in line with lamps available today. This measure provides more clarity for multi-family buildings for the lighting power reduction option. Lamps meeting the higher efficacy
requirement are readily available and appropriate for an optional credit.

www.1000bulbs.com for lamp prices

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
To use this reduced lighting power option to meet C406 requirements in buildings with residential areas this proposal will require higher efficacy lamps in dwelling units and sleeping units. However, these lamps are readily available in the market place, and checking internet sources has found them to actually be less costly than the slightly lower efficacy alternative required under the residential code. LED lamps were found to be about 85% the cost of similar output compact fluorescent lamps. If compared to incandescent lamps, there may be a cost increase, but the life of either the CFL or LED lamps is 10 or 15 times as long, resulting in a much lower cost per year of service.

Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.
Add new definition as follows:

**LUMEN MAINTENANCE CONTROLS**: A lighting control strategy that adjusts luminaire power over time to maintain constant light output as luminaires age, dirt accumulates or both. This strategy allows for energy savings in the life of the system then increases power as the system ages.

**HIGH END TRIM**: A lighting control strategy that sets the required maximum light level for each space.

**SECTION C406**

**ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS**

**C406.1 Requirements.** Buildings shall comply. New buildings shall achieve a total of 10 credits from Tables C406.1(1) through C406.1(5) where the table is selected based on the use group of the building. Where a building contains multiple use groups, credits from each use group shall be weighted by floor area of each group to determine the weighted average building credit. Alternatively, credits shall be as calculated in accordance the relevant subsection of Section C406. Credits from the tables or calculation shall be achieved where a building complies with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

a. Other occupancy groups include all Groups except for Groups B, R, I, E, and M.

b. For occupancy groups listed in Section C406.7.1.

**C406.1.1 Tenant spaces.** Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, tenant spaces shall comply where the entire building complies using credits from Section C406.5, C406.8 or C406.9. Tenant spaces within the buildings shall be deemed to comply with Section C406.5 where the entire building is in compliance.

**Exception:** Previously occupied tenant spaces that comply with this code in accordance with Section C501.

**C406.2 More efficient HVAC equipment performance.** Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent in accordance with Section C406.2.1, C406.2.2, C406.2.3 or C406.2.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from Section C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from Section C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) and Variable refrigerant flow systems not listed in the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 shall be limited to 10 percent of the total building system capacity. Capacity for heating equipment where selecting Section C406.2.1 or C406.2.3 and cooling equipment where selecting Section C406.2.2 or C406.2.4.

Add new text as follows:

**C406.2.1 Five percent heating efficiency improvement** Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

**C406.2.2 Five percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

**C406.2.3 Ten percent heating efficiency improvement** Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

**C406.2.4 Ten percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

Revise as follows:

**C406.4 Enhanced digital lighting controls.** Interior lighting in At least 90 percent of the building floor area shall have interior lighting with the following enhanced lighting controls for luminaires providing general lighting, that shall be located, scheduled and operated in accordance with Section C405.2.2.

1. Luminaires shall be configured for continuous dimming.
2. Luminaires shall be addressed individually. Where individual addressability is not available for the luminaire class type, a controlled group of not more than four luminaries shall be allowed.
3. Not more than eight luminaires shall be controlled together in a daylight zone.
4. Fixtures shall be controlled through a digital control system that includes the following function:
   4.1. Control reconfiguration based on digital addressability.
   4.2. Load shedding.
   4.3. Individual user control of overhead general illumination in open offices.
   4.4. Occupancy sensors shall be capable of being reconfigured through the digital control system.
5. Construction documents shall include submittal of a Sequence of Operations, including a specification outlining each of the functions in Item 4.
6. Functional testing of lighting controls shall comply with Section C408. High end trim controls shall be enabled and configured to limit the initial maximum output or maximum power draw of the controlled lighting to 85 percent or less of full light output or full power draw for both of the following: 6.1 All areas that have lumen maintenance controls 6.2 50% of the remaining floor area.

C406.5 On-site renewable energy. The total minimum ratings of on-site renewable energy systems shall be one of the following:
1. Not less than 1.71 Btu/h per square foot (5.4 W/m²) or 0.50 watts per square foot (5.4 W/m²) of conditioned floor area.
2. Not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.
Buildings shall comply with Section C406.5.1 or C406.5.2.

Add new text as follows:

C406.5.1 Basic renewable credits. The total minimum ratings of on-site renewable energy systems not including systems used for credits under Sections C406.7.2 shall be one of the following:

1. Not less than 0.86 Btu/h per square foot (2.7 W/m²) or 0.25 watts per square foot (2.7 W/m²) of conditioned floor area.
2. Not less than 2 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

C406.5.2 Enhanced Renewable Credits Where the total minimum ratings of on-site renewable energy systems exceeds the rating in C406.5.1(1), additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

\[ \text{AECC}_{RRa} = \text{AECC}_{2.5} \times \frac{RR_a}{RR_t} \] (Equation 4-13)

Where:

\[ \text{AECC}_{RRa} = \text{C406.5.2 additional energy efficiency credits} \]
\[ RR_a = \text{actual total minimum ratings of on-site renewable energy systems in Btu/h, watts per square foot or W/m²} \]
\[ RR_t = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) in Btu/h, watts per square foot or W/m²} \]
\[ \text{AECC}_{2.5} = \text{C406.5.1 credits from Tables C406.1(1) through C406.1(5)} \]

Revise as follows:
C406.7 Reduced energy use in service water heating. Buildings shall comply with Section C406.7.1 and Section C406.7.2, C406.7.3 or C406.7.4, be of the following types to use this compliance method:

1. **Group R-1**: Boarding houses, hotels or motels.
2. **Group I-2**: Hospitals, psychiatric hospitals and nursing homes.
3. **Group A-2**: Restaurants and banquet halls or buildings containing food preparation areas.
4. **Group F**: Laundries.
5. **Group R-2**.
6. **Group A-3**: Health clubs and spas.
7. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

Add new text as follows:

**C406.7.1 Building type.** To qualify for this credit, the building shall contain one be of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following use groups:

1. **Group R-1**: Boarding houses, hotels or motels.
2. **Group I-2**: Hospitals, psychiatric hospitals and nursing homes.
3. **Group A-2**: Restaurants and banquet halls or buildings containing food preparation areas.
4. **Group F**: Laundries.
5. **Group R-2**.
6. **Group A-3**: Health clubs and spas.
7. **Group E**: Schools with full-service kitchens or locker rooms with showers
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

**C406.7.2 Load fraction. Recovered or renewable water heating.** The building service water-heating system shall have one or more of the following that are sized to provide not less than 60-30 percent of the building’s annual hot water requirements, or sized to provide 40-70 percent of the building’s annual hot water requirements if the building otherwise is required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. **On-site renewable energy** water-heating systems.

Add new text as follows:

**C406.7.3 Efficient fossil fuel water heater.** The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95 percent $\text{Et}$ or 0.95 $\text{EF}$. This option shall receive only half the listed credits for buildings required to comply with C404.2.1.

**C406.7.4 Heat pump water heater.** Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average $\text{EF}$ of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

Reason:

**C406 Credits for Enhanced digital lighting controls.**

This proposal builds on top of a proposal (CE218-19) that assigns energy efficiency credits to each option in Section C406. For clarity, that entire base proposal is included here. Additional provisions and table row
modifications are as follows:

- The provisions of Enhanced Digital lighting are clarified to require high end trim tuning, including definitions to support those clarifications.
- The credits in the tables are increased for enhanced digital light control based on the clarified provisions in C406.4 that are expected to produce increased savings.

Compared to the existing enhanced lighting controls in C406.4, this proposal provides for more certain savings through light level tuning with the option of lumen maintenance control.

Enhanced lighting controls (Section C406.4) can save more energy by tuning maximum light levels to just what is needed throughout the building. Making this requirement explicit and requiring documentation can actually achieve greater savings.

In the proposed code language, changes are made to allow for the following:

- Definitions are added for lumen maintenance controls and high end trim. These definitions are adapted from NEMA-LSD-64. The high end trim definition exactly matches the NEMA definition, and the lumen maintenance definition is adjusted to refer to luminaire power rather than lamp power.
- The area required with the specified controls is adjusted to 90%. Under current language, all luminaires in the building would need to meet the control requirements. This does not make sense for areas like mechanical and electrical rooms, stairwells, and restrooms, where the specified controls would not provide an energy benefit.
- The specified controls are required only for luminaires providing general lighting.
- A requirement for high end trim was added for any areas with lumen maintenance controls, plus 50% of the remaining area.

High end trim or tuning accounts for the fact that maximum lighting with full output at the lighting power allowance level typically provides more lighting than necessary, due to increments in luminaire size and limits on exact luminaire spacing. Requiring tuning that reduces light levels and power by at least 15%, along with documentation in the lighting functional testing process will reduce actual light power levels. While the original language for this type of control provides the capability to tune, without the trim requirement, there is not a strong argument for savings actually occurring. Lumen maintenance controls also start with a lower light level and adjust the lighting upward to compensate for lumen and dirt depreciation. Requiring tuning to 85% or lower will result in more savings than the savings shown for the existing requirement without this trim language. In the field, tuning down to 70% light and power levels or lower is often possible.

This proposal addresses lumen maintenance controlled luminaires, but does not require lumen maintenance controls. Lumen maintenance controls will adjust the lighting power over time to increase power as the light output reduces from lamp, dirt and room lumen depreciation. This strategy can save average energy over time, but only if the controls are tuned initially. When these controls are applied, all areas with lumen maintenance control require tuning, with half the remaining area also requiring high end trim tuning. Where lumen maintenance controls are not used, the high trim requirement applies to 50% of the lit area.

Note: Tables C406.1(1) through C406.1(5) include entries for climate zones 1A through 8. Should climate zones 0A and 0B be added to the IECC, use values for 1A in 0A and values for 1B in 0B.

Bibliography:
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal makes the application easier to implement on the one hand. Making the applicability only to 90% of general lighting reduces the cost. Requiring tuning appears to increase the cost; however, it is currently required by C408 in daylighting areas, so the area where tuning is already required could be equivalent to 50% of the lighting area. In all, this proposal is more a clarification and a reinforcement of tuning requirements that are already found for daylighting areas in Section C408.
Add new definition as follows:

**LUMEN MAINTENANCE CONTROLS.** A lighting control strategy that adjusts luminaire power over time to maintain constant light output as luminaires age, dirt accumulates or both. This strategy allows for energy savings in the life of the system then increases power as the system ages.

**HIGH END TRIM.** A lighting control strategy that sets the required maximum light level for each space.

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency requirements. Buildings New buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.

C406.4 Enhanced digital lighting controls. Interior lighting in At least 90 percent of the building floor area shall have interior lighting with the following enhanced lighting controls for luminaires providing general lighting that shall be located, scheduled and operated in accordance with Section C405.2.2, C405.2.

1. Luminaires shall be configured for continuous dimming.
2. Luminaires shall be addressed individually. Where individual addressability is not available for the luminaire class type, a controlled group of not more than four luminaries shall be allowed.
3. Not more than eight luminaires shall be controlled together in a daylight zone.
4. Fixtures shall be controlled through a digital control system that includes the following function:
   4.1. Control reconfiguration based on digital addressability.
   4.2. Load shedding.
   4.3. Individual user control of overhead general illumination in open offices.
   4.4. Occupancy sensors shall be capable of being reconfigured through the digital control system.
5. Construction documents shall include submittal of a Sequence of Operations, including a specification outlining each of the functions in Item 4.
6. Functional testing of lighting controls shall comply with Section C408. High end trim controls shall be enabled and configured to limit the initial maximum output or maximum power draw of the controlled lighting to 85 percent or less of full light output or full power draw for the following:

6.1 All areas that have lumen maintenance controls, and
6.2 50% of the remaining floor area.

Reason: C406 revise digital lighting controls:
Compared to the existing enhanced lighting controls in C406.4, the proposal provides for more certain savings through light level tuning with the option of lumen maintenance control. With the clear requirement for tuning in this proposal, the potential savings is more reliable, and the credits listed in this proposal are higher than the credits for this measure in the base proposal for additional energy efficiency credits.

This proposal will improve the C406.4 requirements to provide more energy savings. Enhanced lighting controls (Section C406.4) can save more energy by tuning maximum light levels to just what is needed throughout the building. Making this requirement explicit and requiring documentation can actually achieve greater savings.

In the proposed code language, changes are made to allow for the following:

- Definitions are added for lumen maintenance controls and high end trim. These definitions are adapted from NEMALSD-64. The high end trim definition exactly matches the NEMA definition, and the lumen maintenance definition is adjusted to refer to luminaire power rather than lamp power.
- The area required with the specified controls is adjusted to 90%. Under current language, all luminaires in the building would need to meet the control requirements. This does not make sense for areas like mechanical and electrical rooms, stairwells, and restrooms, where the specified controls would not provide an energy benefit.
- The specified controls are required only for luminaires providing general lighting.
- A requirement for high end trim was added for any areas with lumen maintenance controls, plus 50% of the remaining area.

High end trim or tuning accounts for the fact that maximum lighting with full output at the lighting power allowance level typically provides more lighting than necessary, due to increments in luminaire size and limits on exact luminaire spacing. Requiring tuning that reduces light levels and power by at least 15%, along with documentation in the lighting functional testing process will reduce actual light power levels. While the original language for this type of control provides the capability to tune, without the trim requirement, there is not a strong argument for savings actually occurring. Lumen maintenance controls also start with a lower light level and adjust the lighting upward to compensate for luminaire and dirt depreciation. Requiring tuning to 85% or lower will result in more savings than the savings shown for the existing requirement without this trim language. In the field, tuning down to 70% light and power levels or lower is often possible.

This proposal addresses lumen maintenance controlled luminaires, but does not require lumen maintenance controls. Lumen maintenance controls will adjust the lighting power over time to increase power as the light output reduces from lamp, dirt and room luminaire depreciation. This strategy can save average energy over time, but only if the controls are tuned initially. When these controls are applied, all areas with lumen maintenance control require tuning, with half the remaining area also requiring high end trim tuning. Where lumen maintenance controls are not used, the high trim requirement applies to 50% of the lit area.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The current proposal does not require more investment, but rather expands existing options permitted under section C406 of the 2018 IECC. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current code. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.

Proposal # 5769

CE230-19
2018 International Energy Conservation Code

Revise as follows:

C406.4 Enhanced digital lighting controls. Interior general lighting in the building shall have the following enhanced lighting controls that shall be located, scheduled and operated in accordance with Section C405.2.2.

1. Luminaires shall be configured for continuous dimming.
2. Luminaires shall be addressed individually. Where individual addressability is not available for the luminaire class type, a controlled group of not more than four luminaries shall be allowed.
3. Not more than eight luminaires shall be controlled together in a daylight zone.
4. Fixtures shall be controlled through a digital control system that includes the following function:
   4.1. Control reconfiguration based on digital addressability.
   4.2. Load shedding.
   4.3. Individual user control of overhead general illumination in open offices.
   4.4. Occupancy sensors shall be capable of being reconfigured through the digital control system.
5. Construction documents shall include submittal of a Sequence of Operations, including a specification outlining each of the functions in Item 4.
6. Functional testing of lighting controls shall comply with Section C408.

Reason:

1. As currently written in the code this control requirement would apply to all lighting fixtures in a project. This is not a problem for most fixtures typically used in commercial construction, but there are all sorts of specialized luminaires or decorative luminaires where it would not be sensible, practical, or cost effective to control in this manner. As a solution to this problem, this proposal limits the requirement for Enhanced Digital Lighting controls to General Lighting, a defined term in IECC.
2. We also propose to remove the requirement for "individual user control of overhead general illumination in open offices". Giving each occupant in an open office their own control of overhead lighting (it is not clear if this means the lighting only over their desk or over the whole space) might lead to less energy use, but it adds a very high level of complexity to the design, construction, and operation of the lighting system that is unlikely to be cost effective. Control systems that provide this type of control are not commonly available.

Requiring individual user control does not align with the Design Light Consortium technical requirements, which qualifies and provides acceptability guidance for enhanced digital lighting controls. Many in the design and energy program communities will not specify an enhanced digital lighting control system without the controls being listed on the Design Light Consortium's Qualified Product List (QLP) for networked lighting controls.

An application requirement for individual user control is out of context; as this provision is a list of functional enhanced digital lighting controls requirements, which includes luminaire configurability, load shedding and occupancy sensor zoning. Removing individual user control will retain proper functional requirements for the provision.
For these reasons, C406.4 as currently written, is highly unlikely to ever be chosen as an additional efficiency option. Making these changes will greatly increase its usability as an additional efficiency option.

**Cost Impact:** The code change proposal will decrease the cost of construction
Will decrease the cost of contraction when C406.4 is applied to open office areas because the code will no longer require the installation of additional lighting controls to provide individual control of overhead lighting.
SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency credit requirements. Buildings shall comply
with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with
   Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Controlled receptacles in accordance with Section C406.10.

a. Other occupancy groups include all Groups except for Groups B, R, I, E, and M.

b. For occupancy groups listed in C406.7.1.

**C406.1.1 Tenant spaces.** Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, C406.7 or C406.10. Where the entire building complies using credits from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance of this section.

**Exception:** Previously occupied tenant spaces that comply with this code in accordance with Section C501.

Revise as follows:

**C406.2 More efficient HVAC equipment performance.** Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. **9)** and **Variable refrigerant flow systems** shall exceed listed in the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent, in accordance with Sections C406.2.1, C406.2.2, C406.2.3 or C406.2.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from Section C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from Section C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) and Variable refrigerant flow systems not listed in the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 shall be limited to 10 percent of the total building system capacity for heating equipment where selecting Section C406.2.1 or C406.2.3 and cooling equipment where selecting Section C406.2.2 or C406.2.4.

Add new text as follows:

**C406.2.1 Five percent heating efficiency improvement.** Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

**C406.2.2 Five percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

**C406.2.3 Ten percent heating efficiency improvement** Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

**C406.2.4 Ten percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

**C406.5 On-site renewable energy.** Buildings shall comply with Section C406.5.1 or C406.5.2. The total minimum ratings of on-site renewable energy systems shall be one of the following:

1. Not less than 1.71 Btu/h per square foot (5.4 W/m²) or 0.50 watts per square foot (5.4 W/m²) of conditioned floor area;
2. Not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Add new text as follows:

**C406.5.1 Basic renewable credits** The total minimum ratings of on-site renewable energy systems, not including systems used for credits under Section C406.7.2, shall be one of the following:
1. Not less than 0.86 Btu/h per square foot (2.7 W/m²) or 0.25 watts per square foot (2.7 W/m²) of conditioned floor area.
2. Not less than 2 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

C406.5.2 Enhanced renewable credit. Where the total minimum ratings of on-site renewable energy systems exceeds the rating in Item 1 of Section C406.5.1, additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

\[ \text{AEEC}_{RR_a} = \text{AEEC}_{2.5} \times \frac{RR_a}{RR_1} \] (Equation 4-13)

Where:

\[ \text{AEEC}_{RR_a} = \text{C406.5.2 additional energy efficiency credits} \]

\[ RR_a = \text{actual total minimum ratings of on-site renewable energy systems (in Btu/h, watts per square foot or W/m²)} \]

\[ RR_1 = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) (in Btu/h, watts per square foot or W/m²)} \]

\[ \text{AEEC}_{2.5} = \text{C406.5.1 credits from Tables C406.1(1) through C406.1(5)} \]

Revise as follows:

C406.7 Reduced energy use in service water heating. Buildings shall comply with Section C406.7.1 and Section C406.7.2, C406.7.3 or C406.7.4, be of the following types to use this compliance method:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

Add new text as follows:

C406.7.1 Building type. To qualify for this credit, the building shall contain one of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following use group:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Group E: Schools with full-service kitchens or locker rooms with showers.
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.
**C406.7.1 Load fraction.** **Recovered or renewable water heating.** The building service water-heating system shall have one or more of the following that are sized to provide not less than 60-30 percent of the building’s annual hot water requirements, or sized to provide 100-70 percent of the building’s annual hot water requirements if the building shall otherwise be required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. On-site renewable energy water-heating systems.

Add new text as follows:

**C406.7.3 Efficient fossil fuel water heater.** The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95 percent Et or 0.95 EF. This option shall receive only half the listed credits for buildings required to comply with Section C404.2.1.

**C406.7.4 Heat pump water heater.** Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average EF of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

**C406.10 Controlled Receptacles** At least 50 percent of all 125 volt 15- and 20-ampere receptacles installed in private offices, open offices, conference rooms, breakrooms, individual workstations, and classrooms, including those installed in modular partitions and modular office workstation systems, shall be controlled as required by this section. Either split receptacles shall be provided, with the top receptacle(s) controlled, or a controlled receptacle shall be located within 12 inches (0.3 m) of each uncontrolled receptacle. Alternatively, non-controlled receptacles in a single modular workstation shall be located not more than 72 inches from a controlled receptacle serving that workstation. Controlled receptacles shall be visibly differentiated from standard receptacles and shall be controlled by one of the following automatic control devices:

1. An occupant sensor that turns receptacle power off when no occupants have been detected for a maximum of 20 minutes.
2. A time-of-day operated control device that turns receptacle power off at specific programmed times and can be programmed separately for each day of the week. The control device shall be capable of providing an independent schedule for each portion of the building not to exceed 5,000 square feet (460 m²) and not to exceed one full floor. The device shall be capable of being overridden for periods of up to two hours by an override switch accessible to occupants. Any individual override switch shall control the controlled receptacles for a maximum area of 5,000 square feet (460 m²).

**Exception:** Receptacles designated for specific equipment requiring 24-hour operation, for building maintenance functions, or for specific safety or security equipment.

**Reason: C406 Credits for Controlled Receptacles**

This proposal builds on top of a proposal that assigns energy efficiency credits to each option in Section C406 (CE218-19). For clarity, that entire base proposal is included here with the following additions or changes:

- Requirements for automatic receptacle controls when extra credits are used for this option in the building.
- Table row additions that provide additional energy efficiency credits for controlled receptacles.
- Addition of this option to the items allowed for tenant spaces.

**Note:** Tables C406.1(1) through C406.1(5) include entries for climate zones 1A through 8. Should climate zones 0A and 0B be added to the IECC, use values for 1A in 0A and values for 1B in 0B.

The code change proposal would provide a credit if occupancy sensor or a time-of-day control devices are
placed on 50% of receptacles installed in private offices, open offices, conference rooms, breakrooms, individual workstations, and classrooms, including those installed in modular partitions and modular office workstation systems. This proposed option is designed to be consistent with the C406 Points Option submitted by the Northwest Energy Codes Group and is based on the PNNL Technical Brief “Relative Credits for Extra Efficiency Code Measures” which can be accessed at http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-28370.pdf.

This measure provides more flexibility to building designers when it is added to the energy efficiency credit choices. The recommended language requires location of controlled receptacles adjacent to non-controlled receptacles. That requirement would avoid “daisy chained” power strips and extension cords from the non-controlled receptacles to their office equipment to avoid their equipment from being automatically turned off. The recommended language was adopted by the Seattle Nonresidential Energy Code and would require that either a split receptacle be installed that would contain both a controlled and uncontrolled receptacle, or the uncontrolled receptacle be located no more than 12” from the controlled receptacle.

Savings Estimate

Controlled receptacles saves energy by turning off unneeded equipment during unoccupied hours. As shown in Figure 3, office equipment is one of the highest energy costs in typical buildings representing 29% of the total cost on a building (Hart and Xie 2014). While the efficiency of office equipment is increasing it still represents a proportionally higher percentage of energy usage in buildings today.

The estimated savings are estimated to be 0.49 kWh/ft² in small office and 0.61 kWh/ft² in large office spaces through reduced equipment run times and other plug loads that are connected to the receptacle. These requirements are currently in ASHRAE Standard 90.1-2016, in the Washington State Nonresidential Energy Code and the Seattle Energy Code.
Bibliography:

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Because Controlled Recetacles are an option as part of proposed credits for additional energy efficiency requirements, there is no requirement to comply with this provision. Designers and code users will have the option to use this credit based on project need and cost. Adding the option may reduce costs where this option is lower in cost than the current C406 options.
Proponent: Harold Jepsen, representing National Electrical Manufacturers Association (harold.jepsen@legrand.us)

2018 International Energy Conservation Code
Add new text as follows:

C406.10 Automation Receptacle Control The following shall be automatically controlled:

1. At least 50% of all 125 V, 15 and 20-amp receptacles installed in enclosed offices, conference rooms, rooms used primarily for copy and/or print functions, breakrooms, classrooms, and individual workstations, including those installed in modular partitions and module office workstation systems.
2. At least 25% of branch circuit feeders installed for modular furniture not shown on the construction documents.
3. Either split controlled receptacles shall be provided, with the top receptacle controlled, or a controlled receptacle shall be located within 12 inches of each uncontrolled receptacle.

This control shall function on:

1. A scheduled basis using a time-of-day operated control device that turns receptacle power off at specific programmed times and can be programmed separately for each day of the week. The control device shall be configured to provide an independent schedule for each portion of the building of not more than 5000 ft² and not more than one floor. The occupant shall be able to manually override an area for not more than two hours. Any individual override switch shall control the receptacles of not more than 5000 ft².
2. An occupant sensor control that shall turn receptacles off within 20 minutes of all occupants leaving a space; or
3. An automated signal from another control or alarm system that shall turn receptacles off within 20 minutes after determining that the area is unoccupied.

All controlled receptacles shall be permanently marked in accordance with NFPA 70 and be uniformly distributed throughout the space. Plug-in devices shall not comply.

Exceptions: Receptacles for the following shall not require an automatic control device:

1. Receptacles specifically designated for equipment requiring continuous operation (24/day, 365 days/year).
2. Spaces where an automatic control would endanger the safety or security of the room or building occupants.
3. Within a single modular office workstation, non-controlled receptacles are permitted to be located more than 12 inches, but not more than 72 inches from the controlled receptacles serving that workstation.
Revise as follows:

C406.1 Requirements. Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Automatic receptacle control in accordance with Section C406.10.

C406.1.1 Tenant spaces. Tenant spaces shall comply with Section C406.2, C406.3, C406.4, C406.6, C406.7 or C406.10. Alternatively, tenant spaces shall comply with Section C406.5 where the entire building is in compliance.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

Reason: This proposal will:

1. Increase building energy efficiency
2. Offer a well-studied, cost effective efficiency measure
3. Maintain building occupant's safe usability
4. Keep enforceability simple
5. Align with other energy efficiency codes, increasing design compliance

Although commercial buildings continue to decrease their energy use through more efficient lighting, mechanical, and domestic water systems, the Miscellaneous Electrical Loads (MELs) energy segment continues to rise. More and more electrical power consuming devices are being plugged into building electrical systems. Some, such as fans, space heaters, printers, monitors, plug-in lamps are left on, when spaces are unoccupied. Other devices may be left plugged in and continue to draw power even when inactive or in standby modes. This wastes energy and is counter to the energy efficiency aim of the IECC.

Further explanation of this proposal can be read in the attachment.

Cost Impact: The code change proposal will increase the cost of construction.
Costs estimated to be $0.26/ft² for small office implementation and $0.19/ft² for large office. Payback estimated at 4.2 years for small office buildings (10,000sqft) and 2.4 years for large office buildings (100,000sqft). Source: 2013 California Building Energy Efficiency Standards CASE report.

Proposal # 4365

CE233-19
2018 International Energy Conservation Code

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency requirements. Buildings New buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.  
2. Reduced lighting power in accordance with Section C406.3.  
3. Enhanced lighting controls in accordance with Section C406.4.  
4. On-site supply of renewable energy in accordance with Section C406.5.  
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.  
6. High-efficiency service water heating in accordance with Section C406.7.  
7. Enhanced envelope performance in accordance with Section C406.8.  
8. Reduced air infiltration in accordance with Section C406.9  
9. Controlled receptacles in accordance with Section C406.10.

C406.1.1 Tenant spaces. Tenant spaces shall comply with Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, C406.7 or C406.10. Where the entire building complies using credits from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance with this section.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

Add new text as follows:

C406.10 Controlled Receptacles At least 50 percent of all 125 volt 15- and 20-ampere receptacles installed in private offices, open offices, conference rooms, breakrooms, individual workstations, and classrooms, including those installed in modular partitions and modular office workstation systems, shall be controlled as required by this section. Either split receptacles shall be provided, with the top receptacle(s) controlled, or a controlled receptacle shall be located within 12 inches (0.3 m) of each uncontrolled receptacle. Alternatively, non-controlled receptacles in a single modular workstation shall be located not more than 72 inches from a controlled receptacle serving that workstation. Controlled receptacles shall be visibly differentiated from standard receptacles and shall be controlled by one of the following automatic control devices:

1. An occupant sensor that turns receptacle power off when no occupants have been detected for a maximum of 20 minutes, or
2. A time-of-day operated control device that turns receptacle power off at specific programmed times and can be programmed separately for each day of the week. The control device shall be capable of providing an independent schedule for each portion of the building not to exceed 5,000 square feet (460 $m^2$) and not to exceed one full floor. The device shall be capable of being overridden for periods of up to two hours by an override switch accessible to occupants. Any individual override switch shall control the controlled receptacles for a maximum area of 5,000 ($460 m^2$).

Exception: Receptacles designated for specific equipment requiring 24-hour operation, for building
maintenance functions, or for specific safety or security equipment.

Reason:
C406 add Controlled Receptacles

This proposal adds a new option in Section C406, increasing flexibility in meeting this additional efficiency requirement. This proposal allows selection of a provision where occupancy sensor or a time-of-day control devices are placed on 50% of receptacles installed in private offices, open offices, conference rooms, breakrooms, individual workstations, and classrooms, including those installed in modular partitions and modular office workstation systems. Modifications include:

- A new subsection added to C406 with provisions for automatic receptacle control.
- The tenant space requirements in C406.1.1 are revised to allow this new option in tenant spaces.

This measure provides more flexibility to building designers when it is added to the energy efficiency requirement choices. The recommended language requires location of controlled receptacles adjacent to non-controlled receptacles. That requirement would avoid “daisy chained” power strips and extension cords from the non-controlled receptacles to their office equipment to avoid their equipment from being automatically turned off. The recommended language was adopted by the Seattle Nonresidential Energy Code and would require that either a split receptacle be installed that would contain both a controlled and uncontrolled receptacle, or the uncontrolled receptacle be located no more than 12” from the controlled receptacle.

Savings Estimate

Controlled receptacles saves energy by turning off unneeded equipment during unoccupied hours. As shown in Figure 1, office equipment is one of the highest energy costs in typical buildings representing 29% of the total cost on a building (Hart and Xie 2014). While the efficiency of office equipment is increasing it still represents a proportionally higher percentage of energy usage in buildings today.

The estimated savings are estimated to be 0.49 kWh/ft² in small office and 0.61 kWh/ft² in large office spaces through reduced equipment run times and other plug loads that are connected to the receptacle. These requirements are currently in ASHRAE Standard 90.1-2016, in the Washington State Nonresidential Energy Code, and the Seattle Energy Code.

Savings is reported in:

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Because Controlled Receptacles are an option in section C406, there is no requirement to comply with this provision. Designers and code users will have the option to use this option based on project need and cost. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current...
code. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.
2018 International Energy Conservation Code

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

Revise as follows:

C406.1 Requirements. Buildings shall comply. New buildings shall achieve a total of 10 credits from Tables C406.1(1) through C406.1(5) where the table is selected based on the use group of the building. Where a building contains multiple use groups, credits from each use group shall be weighted by floor area of each group to determine the weighted average building credit. Credits may also be as calculated in accordance with the relevant subsection of C406. Credits from the tables or calculation shall be achieved where a building complies with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Extra daylit area with daylight responsive controls in accordance with Section C406.10.
