ᵃ for schools with full service kitchens or showers
C406.10 Extra Daylit Area

Other occupancy groups include all Groups except for Groups B, R, I, E, and M.

for occupancy groups listed in C406.7.1.

Revise as follows:

C406.1.1 Tenant spaces. Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, tenant spaces shall comply with Section C406.8 where the entire building is in compliance. C406.7, or C406.10. Where the entire building complies using credits from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply this section.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent, 90.1, in accordance with Sections C406.2.1, C406.2.2, C406.2.3 or C406.2.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) and Variable refrigerant flow systems not listed in the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 shall be limited to 10 percent of the total building system capacity. Capacity for heating equipment where selecting C406.2.1 or C406.2.3 and cooling equipment where selecting C406.2.2 or C406.2.4.

Add new text as follows:

C 406.2.1 Five percent heating efficiency improvement. Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

C 406.2.2 Five percent cooling efficiency improvement. Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

C 406.2.3 Ten percent heating efficiency improvement. Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

C 406.2.4 Ten percent cooling efficiency improvement. Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

C406.5. On-site renewable. Buildings shall comply with Section C406.5.1 or C406.5.2.

Revise as follows:

C C406.5.5 On-site Basic renewable energy. credit The total minimum ratings of on-site renewable energy systems not including systems used for credits under Section C406.7.2 shall be one of the following:

1. Not less than 4.74-0.86 Btu/h per square foot (5.4-2.7 W/m²) or 0.50-0.25 watts per square foot
(5.4-2.7 W/m²) of conditioned floor area.

2. Not less than 3.2 percent of the annual energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Add new text as follows:

C 406.5.2 Enhanced Renewable Credits. Where the total minimum ratings of on-site renewable energy systems exceeds the rating in C406.5.1(1), additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

\[
\text{AEEC}_{PRa} = \text{AEEC}_{2.6} \times \frac{RRa}{RR1} \quad \text{(Equation 4-13)}
\]

Where:

\[
\text{AEEC}_{PRa} = \text{C406.5.2 additional energy efficiency credits}
\]

\[
RRa = \text{actual total minimum ratings of on-site renewable energy systems in Btu/h, watts per square foot or W/m}^2\]

\[
RR1 = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) in Btu/h, watts per square foot or W/m}^2\]

\[
\text{AEEC}_{2.6} = \text{C406.5.1 credits from Tables C406.1(1) through C406.1(5)}
\]

C406.7 Reduced energy use in service water heating. Buildings shall comply with Sections C406.7.1 and either C406.7.2, C406.7.3 or C406.7.4.

Revise as follows:

C406.7.1 Reduced energy use in service water heating. Building Type Buildings shall be of the following types to use this compliance method. To qualify for this credit, the building shall contain one of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following use groups:

1. Group R-1: Boarding houses, hotels or motels.
2. Group I-2: Hospitals, psychiatric hospitals and nursing homes.
3. Group A-2: Restaurants and banquet halls or buildings containing food preparation areas.
5. Group R-2.
7. Group E: Schools with full-service kitchens or locker rooms with showers.
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

C406.7.2 Load fraction. Recovered or renewable water heating The building service water-heating system shall have one or more of the following that are sized to provide not less than 60-30 percent of the building’s annual hot water requirements, or sized to provide 100-70 percent of the building’s annual hot water requirements if the building shall otherwise be required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. On-site renewable energy water-heating systems.
Add new text as follows:

C406.7.3 Efficient fossil fuel water heater. The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95% Et or 0.95 EF. This option shall receive only half the listed credits for buildings required to comply with C404.2.1.

C406.7.4 Heat pump water heater. Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average EF of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

C406.10 Extra Daylit Area Building shall not use the energy efficiency credits for Section C406.7, enhanced lighting control, and shall provide continuous dimming daylight responsive controls for 150 percent of the area required to have daylight responsive controls in toplit zones and sidelit zones in Section C405.2.3 or as required by Section C402.4.1.1. Toplit and sidelit zones as defined in Sections C405.2.3.2 and C405.2.3.3 shall be controlled separately from adjacent daylight zones.

Reason:
C406 Credits for Added Daylighting Area

This proposal builds on top of a proposal that assigns energy efficiency credits to each option in Section C406 (CE218-19). For clarity, that entire base proposal is included here with additional provisions and table row additions that provide an additional energy efficiency credit option when extra daylit area included in the building. As part of the comprehensive analysis of C406 measures that is listed in the bibliography, the relative energy cost savings for each measure was determined. Then points or credits were assigned to each measure by climate zone and building type based on one point per 0.25% building cost savings.

This proposal allows credit for increased daylighting area in Section C406 where extra efficiency options are required and includes the following:

- Adds provisions to increase the daylit area to 150% of prescriptively required area.
- Add rows with appropriate credits to the 5 occupancy group tables for this provision.

The current daylighting requirements apply only to what are considered primary daylit zones. These are toplit and sidelit zones as defined in Sections C405.2.3.2 and C405.2.3.3. This measure extends the primary daylit area by adding 50% more daylit area.

Expanding the daylit control area (Section C406.10) saves energy by reducing lighting power when daylighting is available in these areas. This measure provides more flexibility to building designers when it is added to the energy efficiency credit choices. It specifically provides an expansion in the daylit area, which allows lighting to be reduced in a larger portion of the building with daylight responsive controls. The proposal requires separate control of the luminaire light levels in primary and secondary daylit areas.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The current proposal does not require more investment, but rather expands existing options permitted under the 2018 IECC. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current code. In some cases, costs may be reduced, as the outlined approach provides partial credit for selected items as well as credit for items that may have previously been included in the building design without credit. Costs, and cost effectiveness, are not evaluated for individual measures due to the vast number of potential combinations amongst building types, climates, and selected options. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.
2018 International Energy Conservation Code

C406.1 Requirements. Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Extra Daylit Area with Daylight Responsive Controls in accordance with Section C406.10.

C406.1.1 Tenant spaces. Tenant spaces shall comply with Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, C406.7 or C406.10. Where the entire building complies using Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

Add new text as follows:

C406.10 Extra Daylit Area Building shall not use the energy efficiency credits for Section C406.7, enhanced lighting control, and shall provide continuous dimming daylight responsive controls for 150 percent of the area required to have daylight responsive controls in top lit zones and sidelit zones in Section C405.2.3 or as required by Section C402.4.1.1. Top lit and sidelit zones as defined in Sections C405.2.3.2 and C405.2.3.3 shall be controlled separately from adjacent daylight zones.

Reason:

C406 add Added Daylighting Area

This proposal adds a new option in Section C406, increasing flexibility in meeting this additional efficiency requirement. This proposal allows selection of a provision with increased daylighting area in Section C406 where extra efficiency options are required and includes the following:

- Adds provisions to increase the daylit area to 150% of prescriptively required area.

The current daylighting requirements apply only to what are considered primary day lit zones. These are top lit and sidelit zones as defined in Sections C405.2.3.2 and C405.2.3.3. This measure extends the primary day lit area by adding 50% more day lit area.

Expanding the daylit control area (Section C406.10) saves energy by reducing lighting power when daylighting is available in these areas. This measure provides more flexibility to building designers.
when it is added to the energy efficiency credit choices. It specifically provides an expansion in the daylit area, which allows lighting to be reduced in a larger portion of the building with daylight responsive controls. The proposal requires separate control of the luminaire light levels in primary and secondary daylit areas.

**Bibliography:** *Savings for this measure is illustrated here:*

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The current proposal does not require more investment, but rather expands existing options permitted under section C406 of the 2018 IECC. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current code. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.

Proposal # 5766

CE236-19
2018 International Energy Conservation Code

Revise as follows:

C406.1 Requirements. Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Include an energy monitoring system in accordance with C406.10.

Add new text as follows:

C406.10 Energy Monitoring. Buildings shall comply with Section C406.10.1 through C406.10.5. Buildings shall be equipped to measure, monitor, record and report energy consumption data for each end-use category required by Section C406.10.2.

C406.10.1 Electrical energy metering. For electrical energy, including all electrical energy supplied to the building and its associated site, including but not limited to site lighting, parking, recreational facilities, and other areas that serve the building and its occupants, meters or other approved measurement devices shall be provided to collect energy consumption data for each end-use category required by Section C406.10.2.

C406.10.2 End-use metering categories. Meters or other approved measurement devices shall be provided to collect energy use data for each end-use category listed in Table 406.10.2. These meters shall have the capability to collect energy consumption data for the whole building or for each separately metered portion of the building. Where multiple meters are used to measure any end-use category, the data acquisition system shall total all of the energy used by that category. Not more than 5 percent of the measured load for each of the end-use categories listed in Table 406.10.2 is permitted to be from a load not within the category.

Exceptions:

1. HVAC and water heating equipment serving only an individual dwelling unit does not require end-use metering.
2. End-use metering is not required for fire pumps, stairwell pressurization fans or any system that operates only during testing or emergency.

<table>
<thead>
<tr>
<th>TABLE 406.10.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY USE CATEGORIES</td>
</tr>
<tr>
<td>LOAD CATEGORY</td>
</tr>
<tr>
<td>--------------------------------------</td>

<tr>
<td>Interior lighting</td>
</tr>
<tr>
<td>Exterior lighting</td>
</tr>
<tr>
<td>Plug loads</td>
</tr>
<tr>
<td>Process loads</td>
</tr>
<tr>
<td>Building operations and other miscellaneous loads</td>
</tr>
</tbody>
</table>

**C406.10.3 Meters.** Meters or other measurement devices required by this Section shall be configured to automatically communicate energy consumption data to the data acquisition system required by Section C406.10.4. Source meters shall be allowed to be any digital-type meter. Lighting, HVAC, or other building systems that can monitor their energy consumption shall be permitted instead of meters. Current sensors shall be permitted, provided that they have a tested accuracy of +/-2 percent. Required metering systems and equipment shall have the capability to provide at least hourly data that is fully integrated into the data acquisition system and graphical energy report in accordance with Sections 406.10.4 and C406.10.5.

**C406.10.4 Data acquisition system.** A data acquisition system shall have the capability to store the data from the required meters and other sensing devices for a minimum of 36 months. The data acquisition system shall...
have the capability to store real-time energy consumption data and provide hourly, daily, monthly, and yearly
logged data for each end-use category required by Section C406.10.2.

C406.10.5 Graphical energy report. A permanent and readily accessible reporting mechanism shall be
provided in the building that is accessible by building operation and management personnel. The reporting
mechanism shall have the capability to graphically provide the energy consumption for each end-use category
required by Section C406.10.2 at least every hour, day, month and year for the previous 36 months.

Reason: The investment made for the infrastructure of a building in order to comply with the IECC is significant.
The assumption that is currently made upon commissioning a facility is that energy efficiency measures will not
degrade, or go out of calibration, over time and their energy consumption will not increase as time passes from
the time they were commissioned. Such an assumption is completely inaccurate and any payback assumed for
energy efficient infrastructure investments will be lengthened, thereby reducing the ROI and increasing the
payback period. The only means to retain the energy performance of a building is to continuously monitor
energy consumption levels of various energy consuming systems and compare them to previous levels.
Monitoring sub-systems provides key indications when changes have been made or systems are not operating
to specification, which increases energy consumption. Examples include, but are not limited to:
1. Increased energy consumption in HVAC system loads will point to failures in motors, drive systems, bearings,
etc.
2. Degrading building envelope
3. Configuration changes to the building that may drive increased energy consumption.
4. Increase of energy consumption from lighting loads may indicate changes in arrangement of the office space
that resulted in reduced lighting loads may indicate change in arrangement of the office space that resulted in
reduced lighting driving the installation of more lighting above permitted energy code levels, failure of occupant
sensors, inappropriate lighting schedules, lamps that need to be replaced or cleaned, etc.
5. Monitoring plug loads will indicate then computer equipment is left on during non-working hours and use of
space heaters that compromise the efficiency of the facility due to set points on the HVAC system.

The requirements in this proposal save energy by continually monitoring and reporting actionable energy
consumption data to building owners and operators. For large buildings, this data is further broken out by the
major sub-systems (HVAC, lighting, process loads, and plug loads). There are well documented studies that
demonstrate the energy savings from metering and monitoring systems. Several state energy codes have
recognized the benefits and require energy monitoring to support a continual high level of performance from the
energy efficient investment.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The code change proposal “will” increase the cost of construction because it will require additional hardware,
software and labor during installation. Providing specific cost would violate antitrust laws, however the following
link to a report provided by the GSA demonstrates an example of cost and savings:

Proposal # 4428

CE237-19
2018 International Energy Conservation Code

SECTION C202
GENERAL DEFINITIONS

Add new definition as follows:

**ELECTRICAL ENERGY STORAGE SYSTEM (EESS).** A system used to provide standby or emergency power, an uninterruptable power supply, load shedding, load sharing or similar capabilities in accordance with Section 1206 of the *International Fire Code*.

**LOAD.** A portion of a system that consumes electric energy. The total electrical load of a building is the sum of all electricity consuming appliances, lights and systems, necessary for a building to function as designed.

**ON-PEAK.** The time of use during which the cost per kiloWatt-hour (kWh) is the highest and when the maximum generation resources are required to supply electricity to the customer.

**OFF-PEAK.** The time of use during which the cost per kiloWatt-hour (kWh) is the lowest and when generation resources are being underutilized.

**ENERGY MANAGEMENT SYSTEM.** An electronic system that protects stationary storage batteries from operating outside of their safe operating parameters, and generates an alarm and trouble signal for off normal conditions.

SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS

Revise as follows:

**C406.1 Requirements.** Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Provision of an electrical energy storage system (EESS) controlled via an energy management system that shall be programed to shift a portion of the building load from on-peak to off-peak, in accordance with Section C406.10.

Add new text as follows:

ICC COMMITTEE ACTION HEARINGS :::: April, 2019
C406.10 Electrical energy storage system (EESS). EESS shall be controlled by an energy management system that is programmed to shift the load from on-peak to off-peak.

C406.10.1 System storage capabilities. The system shall be capable of storing the following:

1. Not less than 0.05 watts per square foot (0.54 W/m²) of conditioned floor area.
2. Not less than 10 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Reason: The conservation of energy and its related cost are the foundation of the IECC. Demand charges make a large impact on a businesses' utility bill. The inclusion of energy storage will allow these businesses to shift that load from on-peak (most expensive per kw) to off-peak (least expensive per kw) and thus reduce their demand charges. Utilizing off-peak energy to charge up the energy storage for use during on-peak times results in efficient use of the energy generation facilities available to the business.

Definitions that are common in the utility world are not defined in the codes. Utilities clearly indicate on their websites the on-peak and off-peak hours, as well as the cost difference between a kw based upon the time of use. Referencing definitions for EESS from the 2018 IFC and Load calculations clearly being defined in 2017 NFPA Art.220.40, facilitates consistency between codes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change provides another option within Section C406, allowing businesses to utilize their energy efficiently. The shift of a load from on-peak period to off-peak is an important aspect of the effective use of energy. This code change also provides definitions that are common in the utility world and are necessary for the inclusion of energy storage in the effective use of energy. Referencing definitions in the IFC and the NEC facilitate consistancy between codes.

Proposal # 5032

CE238-19
CE239-19

IECC: C202, C406.1, C406.10 (New)

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code

Add new definition as follows:

FAULT DETECTION AND DIAGNOSTICS (FDD) SYSTEM. A software platform that utilizes building analytic algorithms to convert data provided by sensors and devices to automatically identify faults in building systems and provide a prioritized list of actionable resolutions to those faults based on cost or energy avoidance, comfort and maintenance impact.

Revise as follows:

C406.1 Requirements. Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Include a fault detection and diagnostics (FDD) system in accordance with Section C406.10.

Add new text as follows:

C406.10 Fault detection and diagnostics system. A fault detection and diagnostics system shall be installed to monitor the HVAC system's performance and automatically identify faults. The system shall:

1. Include permanently installed sensors and devices to monitor the HVAC system's performance;
2. Sample the HVAC system performance at least once per 15 minutes;
3. Automatically identify and report HVAC system faults;
4. Automatically notify authorized personnel of identified HVAC system faults;
5. Automatically provide prioritized recommendations for repair of identified faults based on analysis of data collected from the sampling of the HVAC system performance; and
6. Be capable of transmitting the prioritized fault repair recommendations to remotely located authorized personnel.

Reason: Energy efficiency of a new building's HVAC system will degrade over time caused by poorly maintained, failing and improperly controlled equipment. The proposed FDD requirement will reduce that degradation by detecting HVAC system faults and notifying building operators so that actions may be taken to reduce energy consumption of the building. Additionally, FDD systems are being utilized to drive operational efficiency, make better use of maintenance personnel, and resolve comfort issues.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. If the alternative being proposed to the list of additional energy efficiency measures by this proposal is selected, it “will” increase the cost of construction because it will require additional hardware, software and labor during...
installation. Providing specific cost would violate antitrust laws, however a published example of cost and savings is provided from the following link https://ecobuilding.schneider-electric.com/documents/10807/217223/Lab+Project+Building+Analytics+Case+Study/a6d8b9b6-7fdd-4e87-a90b-c98ece595a25: Setup/install cost - $23,190, Annual maintenance cost - $35,407, and Annual savings - $286,000.

Proposal # 4438

CE239-19
SECTION C406
ADDITIONAL EFFICIENCY PACKAGE OPTIONS REQUIREMENTS

C406.1 Requirements. Additional energy efficiency requirements shall apply to new buildings. New buildings shall comply with the requirements of this section and achieve a total of 10 credits from Tables C406.1(1) through C406.1(5) where the table is selected based on the use group of the building. Where a building contains multiple use groups, credits from each use group shall be weighted by floor area of each group to determine the weighted average building credit. Credits may also be calculated in accordance with the relevant subsection of C406. Credits from the tables or calculation shall be achieved where a building complies with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Efficient Kitchen Equipment in accordance with Section C406.10.

Add new text as follows:

a. Other occupancy groups include all Groups except for Groups B, R, I, E, and M.
b. For occupancy groups listed in C406.7.1.

**C406.1.1 Tenant spaces.** Tenant spaces shall comply with sufficient options from Tables C406.1(1) through C406.1(5) to achieve a minimum number of 5 credits, where credits are selected from Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, C406.7 or C406.10. Where the entire building complies using credits
from Section C406.5, C406.8 or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance with this section.

**Exception:** Previously occupied tenant spaces that comply with this code in accordance with Section C501.

**C406.2 More efficient HVAC equipment performance.** Equipment shall exceed the minimum efficiency requirements listed in Tables C403.3.2(1) through C403.3.2(7) by 10 percent, in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. and Variable refrigerant flow systems shall exceed listed in the energy efficiency provisions of ANSI/ASHRAE/IESNA 90.1 by 10 percent in accordance with Sections C406.2.1, C406.2.2, C406.2.3 or C406.2.4. Equipment shall also meet applicable requirements of Section C403. Energy efficiency credits for heating shall be selected from C406.2.1 or C406.2.3 and energy efficiency credits for cooling shall be selected from C406.2.2 or C406.2.4. Selected credits shall include a heating or cooling energy efficiency credit or both. Equipment not listed in Tables C403.3.2(1) through C403.3.2(7) and Variable refrigerant flow systems not listed in the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 shall be limited to 10 percent of the total building system capacity capacity for heating equipment where selecting C406.2.1 or C406.2.3 and cooling equipment where selecting C406.2.2 or C406.2.4.

Add new text as follows:

**C406.2.1 Five percent heating efficiency improvement** Equipment shall exceed the minimum heating efficiency requirements by 5 percent.

**C406.2.2 Five percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 5 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

**C406.2.3 Ten percent heating efficiency improvement** Equipment shall exceed the minimum heating efficiency requirements by 10 percent.

**C406.2.4 Ten percent cooling efficiency improvement** Equipment shall exceed the minimum cooling and heat rejection efficiency requirements by 10 percent. Where multiple cooling performance requirements are provided, the equipment shall exceed the annual energy requirement, including IEER, SEER, and IPLV.

Revise as follows:

**C406.5 On-site renewable energy.** Buildings shall comply with Section C406.5.1 or C406.5.2. The total minimum ratings of on-site renewable energy systems shall be one of the following:

1. Not less than 1.71 Btu/h per square foot (5.4 W/m²) or 0.50 watts per square foot (5.4 W/m²) of conditioned floor area.
2. Not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

**C406.5 C406.5.1 On-site Basic renewable energy credits** The total minimum ratings of on-site renewable energy systems not including systems used for credits under Section C406.7, shall be one of the following:

1. Not less than 1.71 7.86 Btu/h per square foot (5.4 2.7 W/m²) or 0.50 0.25 watts per square foot (5.4 2.7 W/m²) of conditioned floor area.
2. Not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

Add new text as follows:

**C406.5.2 Enhanced Renewable Credits** Where the total minimum ratings of on-site renewable energy...
systems exceeds the rating in C406.5.1(1), additional energy efficiency credits shall be determined based on Equation 4-13, rounded to the nearest whole number.

$$\text{AEEC}_{RR_a} = \text{AEEC}_{2.5} \times \frac{RR_a}{RR_1} \text{(Equation 4-13)}$$

Where:

$$\text{AEEC}_{RR_a} = \text{C406.5.2 additional energy efficiency credits}$$

$$RR_a = \text{actual total minimum ratings of on-site renewable energy systems in Btu/h, watts per square foot or W/m}^2)$$

$$RR_1 = \text{minimum ratings of on-site renewable energy systems required by C406.5.1(1) in Btu/h, watts per square foot or W/m}^2)$$

$$\text{AEEC}_{2.5} = \text{C406.5.1 credits from Tables C406.1(1) through C406.1(5)}$$

Revise as follows:

**C406.7 Reduced energy use in service water heating.** Buildings shall comply with Sections C406.7.1 and either C406.7.2, C406.7.3 or C406.7.4, be of the following types to use this compliance method:

1. **Group R-1**: Boarding houses, hotels or motels.
2. **Group I-2**: Hospitals, psychiatric hospitals and nursing homes.
3. **Group A-2**: Restaurants and banquet halls or buildings containing food preparation areas.
4. **Group F**: Laundries.
5. **Group R-2**.
6. **Group A-3**: Health clubs and spas.
7. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

**C406.7.1 Reduced energy use in service water heating. Building Type** Buildings shall be of the following types to use this compliance method. To qualify for this credit, the building shall contain one of the following use groups and the additional energy efficiency credit shall be prorated by conditioned floor area of the portion of the building comprised of the following use groups:

1. **Group R-1**: Boarding houses, hotels or motels.
2. **Group I-2**: Hospitals, psychiatric hospitals and nursing homes.
3. **Group A-2**: Restaurants and banquet halls or buildings containing food preparation areas.
4. **Group F**: Laundries.
5. **Group R-2**.
6. **Group A-3**: Health clubs and spas.
7. **Group E**: Schools with full-service kitchens or locker rooms with showers.
8. Buildings showing a service hot water load of 10 percent or more of total building energy loads, as shown with an energy analysis as described in Section C407.

**C406.7.2 Load fraction. Recovered or renewable water heating** The building service water-heating system shall have one or more of the following that are sized to provide not less than 60-30 percent of the building’s annual hot water requirements, or sized to provide 40-70 percent of the building’s annual hot water requirements if the building is otherwise required to comply with Section C403.9.5:

1. Waste heat recovery from service hot water, heat-recovery chillers, building equipment, or process equipment.
2. **On-site renewable energy** water-heating systems.
C406.7.3 Efficient fossil fuel water heater The combined input-capacity-weighted-average equipment rating of all fossil fuel water heating equipment in the building shall be not less than 95% Et or 0.95 EF. This option shall receive only half the listed credits for buildings required to comply with C404.2.1.

C406.7.4 Heat pump water heater Where electric resistance water heaters are allowed, all service hot water system heating requirements shall be met using heat pump technology with a combined input-capacity-weighted-average EF of 3.0. Air-source heat pump water heaters shall not draw conditioned air from within the building, except exhaust air that would otherwise be exhausted to the exterior.

C406.10 Efficient Kitchen Equipment For buildings and spaces designated as Group A-2 or facilities that include a commercial kitchen with at least one gas or electric fryer, all fryers, dishwashers, steam cookers and ovens shall comply with all of the following:

1. Achieve performance levels in accordance with the equipment specifications listed in Tables C406.10(1) through C406.10(4) when rated in accordance with the applicable test procedure.
2. Be installed prior to the issuance of the Certificate of Occupancy.
3. Have associated performance levels listed on the construction documents submitted for permitting.

Energy efficiency credits for efficient kitchen equipment shall be independent of climate zone and determined based on Equation 4-14, rounded to the nearest whole number.

\[ AEEC_K = 20 \times \frac{Area_K}{Area_B} \text{ (Equation 4-14)} \]

Where:

\( AEEC_K \) = C406.10 additional energy efficiency credits

\( Area_K \) = Floor area of full service kitchen (ft\(^2\) or m\(^2\))

\( Area_B \) = Gross floor area of building (ft\(^2\) or m\(^2\))

\(P = \) Pan Capacity: The number of steam table pans the combination oven is able to accommodate as per the ASTM F1495-14a standard specification.

**Add new standard(s) as follows:**

**ASTM F1361-17: Standard Test Method for Performance of Open Deep Fat Fryers**

**ASTM F2144-17: Standard Test Method for Performance of Large Open Vat Fryers**

**ASTM F1484-18: Standard Test Method for Performance of Steam Cookers**

F1920-15: Standard Test Method for Performance of Rack Conveyor Commercial Dishwashing Machines

F2861-17: Standard Test Method for Enhanced Performance of Combination Oven in Various Modes

F2093-18: Standard Test Method for Performance of Rack Ovens

F1495-14a: Standard Specification for Combination Oven Electric or Gas Fired

Reason: C406 Credits for Efficient Kitchen Equipment
Kitchen equipment uses a large share of building energy use in restaurants, schools, dormitories, hotels, and other facilities with full service kitchens. More efficient equipment saves energy by improving the heat transfer to the cooking process, either through better equipment insulation or other innovations in the appliances. This proposal provides more flexibility to building designers when it is added to the energy efficiency credit choices. It specifically addresses the large energy use of kitchen equipment.

This proposal allows credit for efficient kitchen equipment in Section C406 where extra efficiency options are required. There is a separate proposal that modifies Section C406 from the current requirement to select one of the listed options, to assigning credits to each measure and requiring a certain number of credits (CE218-19).
For clarity, that proposal is included here. In addition to the changes that are the same as that proposal, this proposal adds:

- Requirements for a new kitchen equipment efficiency option.
- A formula to calculate the extra efficiency credits based on the ratio of kitchen area to building area.
- Adding the reference to the new kitchen equipment efficiency credits in the tenant section (C406.1.1).

**Bibliography:**

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The current proposal does not require more investment, but rather expands existing options permitted under the 2018 IECC Section C406. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current code. In some cases, costs may be reduced, as the outlined approach provides partial credit for selected items as well as credit for items that may have previously been included in the building design without credit. Costs, and cost effectiveness, are not evaluated for individual measures due to the vast number of potential combinations amongst building types, climates, and selected options. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.

**Staff Analysis:** A review of the standards proposed for inclusion in the code, ASTM F1361-17, F2144-17, F1484-18, F1696-18, F1920-15, F1496-13, F2861-17, F2093-18 and F1495-14a with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 4927

CE240-19
C406.1 Requirements. Additional energy efficiency requirements. Buildings new buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Efficient Kitchen Equipment in accordance with Section C406.10.

C406.1.1 Tenant spaces. Tenant spaces shall comply with Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively, C406.7, or C406.10. Where the entire building complies with Section C406.5, C406.8, or C406.9, tenant spaces within the building shall be deemed to comply with Section C406.5 where the entire building is in compliance with this section.

Exception: Previously occupied tenant spaces that comply with this code in accordance with Section C501.

Add new text as follows:

C406.10 Efficiency Kitchen Equipment. For buildings and spaces designated as Group A-2 or facilities that include a commercial kitchen with at least one gas or electric fryer, all fryers, dishwashers, steam cookers and ovens shall comply with all of the following:

1. Achieve performance levels in accordance with the equipment specifications listed in Tables C406.10 (1) through (4) when rated in accordance with the applicable test procedure.
2. Be installed prior to the issuance of the Certificate of Occupancy.
3. Have associated performance levels listed on the construction documents submitted for permitting.

Reason: C406 add Efficient Kitchen Equipment

This proposal adds a new option in Section C406, increasing flexibility in meeting this additional efficiency requirement. This proposal allows selection of a provision with high efficiency kitchen equipment in Section C406 where extra efficiency options are required and includes the following:

- Adds provisions to improve kitchen equipment efficiency.
- Revises Section C406.1.1 on tenant spaces to include the new kitchen equipment option in the tenant space portion and update the building compliance portion based on whole building compliance.

Kitchen equipment uses a large share of building energy use in restaurants, schools, dormitories, hotels, and other facilities with full service kitchens. More efficient equipment saves energy by improving the heat transfer to the cooking process, either through better equipment insulation or other innovations in the appliances. This proposal provides more flexibility to building designers when it is added to the energy efficiency credit choices. It specifically addresses the large energy use of kitchen equipment.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The current proposal does not require more investment, but rather expands existing options permitted under the 2018 IECC. The intention is to identify additional options to increase flexibility and more effectively utilize new technologies and construction practices. There is not expected to be an increased cost, as this simply increases the options for C406 beyond what is included in current code. Actual costs will vary based on the items selected by the building designer—architects, engineers, and other involved trades—based on the needs and goals of the individual project.
2018 International Energy Conservation Code

Revise as follows:

C406.1 Requirements. Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9.
9. Electric Vehicle Supply Equipment in accordance with Section 406.11.

Add new text as follows:

C406.11 Electric Vehicle Supply Equipment. In buildings with at least 20 parking spaces, electric vehicle charging stations rated at 208/240 Volts and 40-80 Amps (Level 2) shall be installed to serve at least 5 percent of the parking spaces. Fractional values shall be rounded up to the nearest whole number.

Reason: There are now over 1 million electric vehicles being driven in the United States. As of November 2018, over 300,000 light duty vehicles were sold in the United States. According to a report published by the Edison Electric Institute and the Edison Foundation Institute for Electric Innovation:

- The stock of EVs in the US is projected to reach **18.7 million in 2030**, up from slightly more than 1 million at the end of 2018. This is approximately 7% of the 259 million vehicles (cars and light trucks) expected to be on U.S. roads in 2030.
- It took 8 years to sell 1 million EVs. The report projects that the next 1 million EVs will be on the road in less than 3 years—by early 2021.
- Annual sales of EVs will exceed 3.5 million vehicles in 2030, reaching more than 20 percent of annual vehicle sales in 2030. EV sales are estimated to be 1.4 million in 2025.

Most importantly,

- About 9.6 million charge ports will be required to support the 18.7 million EVs in 2030. This represents a significant investment in EV charging infrastructure. About 1.2 million Level 2 charging ports will be needed at workplaces, according to the report.

This proposal provides an option to install the EV charging station at the lowest cost - when a building is being built.
In addition, Level 2 charging stations are compatible with all electric vehicles that are sold in the US (which have charging connections that meet the SAE J1772 specifications), and they can provide anywhere from 10 to 50 miles of driving range per hour of charging (depending on the size of the EV battery and the on-board charging rate). There are multiple vendors of Level 2 charging stations, and there are state and utility incentives available in many parts of the US for their installation.

This proposal will improve the efficiency of transportation associated with the building (transportation that moves people, products, and services to and from the building). Electric vehicles get anywhere from 80 to over 130 miles per gallon equivalent (MPGe).

**Bibliography:** EEI and IEI, *Electric Vehicle Sales Forecast and the Charging Infrastructure Required Through 2030*, November 2018

**Cost Impact:** The code change proposal will increase the cost of construction
This is one of several efficiency options that increase the cost of construction. For Level 2 charging stations, the total installation costs per station will vary from $1000 to over $2000, depending on the number of stations installed and any addition conduits/raceways/panel spaces that are needed. The cost for these stations are likely to be similar or lower than the cost of other efficiency options in Section C406.

Proposal # 4457

CE243-19

IECC: C407.3

Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

Revise as follows:

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

**Exception:** Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

**Reason:** This is an editorial change to be consistent with the language that is already in Section R405.3. This information can be found at the DOE/EIA State Energy Data System website: https://www.eia.gov/state/seds/

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is an editorial change / update that has no cost impact.

Proposal # 4706
2018 International Energy Conservation Code

Revise as follows:

**C407.3 Performance-based compliance.** Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

**Exception:** Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

**Reason:** The goal should be to reduce the use of non-renewable energy, not to limit the use of renewable energy. Most of this type of limitation is an attempt by some types of products to restrict their competition. Very high efficiency and near zero energy buildings are usually well above 5% renewable energy. Many commercial buildings need off-site renewables to get to very low net energy. There simply is not enough roof top on large buildings to get sufficient renewable energy to get to very low levels of net energy use. Advocating very low or zero energy is inconsistent with advocating renewables must to onsite. Many times it simply is not possible to find the needed surface area on a large building.

**Cost Impact:** The code change proposal will decrease the cost of construction. Renewables can be part of the least cost way to get to low energy buildings.
CE245-19
IECC: C407.3

Proponent: Joseph H. Cain, Solar Energy Industries Association (SEIA), representing Solar Energy Industries Association (SEIA) (JoeCainPE@gmail.com)

2018 International Energy Conservation Code

Revise as follows:

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design shall be permitted to include renewable energy systems.

Exception: Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison.

Reason: Effective integration of energy efficiency measures and renewable energy systems is critical to the future of energy codes and green/stretch/reach codes. At the time of submittal of these code change proposals, there are four states with 100% renewable energy goals: Hawaii, California, New Jersey, and New York. Other communities are committing to renewable energy goals through their own local renewable goals for power supply or for installation of renewable energy systems. Distributed Generation (DG) is an important component of these overall portfolio standards.

When looking forward for future energy codes, Zero Net Energy and Zero Carbon are common goals/aspirations. It should be clear that we cannot get to Zero Net Energy or Zero Carbon buildings without renewable energy systems. This is just as true for commercial buildings as for residential buildings.

In the process of development of the 2018 IECC, Proposal CE250-16 sought to constrain the contribution of renewable energy systems in the performance approach. The original proposal set a renewable backstop of 10% of the energy cost, which is so restrictive that builders are unlikely to install a renewable energy system for the purpose of code compliance. Either they do or they don’t, but a 10% constraint does not allow enough compliance credit to influence the economics or the decision to install or not install a solar PV system with the original construction. During the Committee Action Hearings, a modification by a committee member lowered the constraint even further, to only 5% of energy cost. By inspection, 5% is approximately equal to 0%. Projects that include a renewable energy system to offset consumption of energy and reduce energy flows at the meter are not rewarded in this revised approach. This does not provide an attractive option for builders to install renewable energy systems.

This proposal gives builders credit for what they do, and encourages the use of energy efficiency measures plus renewable energy systems.
Cost Impact: The code change proposal will not increase or decrease the cost of construction.
This proposal encourages the installation of renewable energy systems, which provides more flexibility to the
builder and could result in either increased or decreased first cost of construction, depending on builder
choices.

Proposal # 5562

CE245-19
CE246-19

IECC: C407.3

Proponent: Ted Williams, representing American Gas Association (twilliams@aga.org)

2018 International Energy Conservation Code

Revise as follows:

C407.3 Performance-based compliance. Compliance based on total building performance requires that a proposed building (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration's State Energy Price and Expenditure Report. Code officials shall be permitted to require time-of-use pricing in energy cost calculations. The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost. The amount of renewable energy purchased from off-site sources shall be the same in the standard reference design and the proposed design.

Exception: Jurisdictions that require site energy (1 kWh = 3413 Btu) rather than energy cost as the metric of comparison. Where energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area is substituted for the energy cost, the source energy multipliers shall be 3.16 for electricity and 1.1 for fuels other than electricity, or other multipliers for national or regional annual average energy consumption from nationally-recognized and validated data sources.

Reason: The proposed change brings C407.3 into greater consistency with R405.3 and source energy metric usage in Federal energy programs including Energy Star for Commercial Buildings and Home Energy Score. This revised exception provides the only means of assessing energy performance on fuel cycle energy consumption and ultimately carbon footprints since site energy metrics alone cannot account for these upstream energy system losses. In addition, the allowance in the proposed exception language for use of “other multipliers” addresses a persistent criticism of national average multipliers, which may not reflect regional or local mixes of renewable energy in meeting building demands, and encourages authorities having jurisdiction to use locally-relevant multipliers that are available from utilities and other sources. Also, greater usefulness of the exception is critical since the basic requirements of C407.3 focusing on energy cost is not consistent with the intent of the IECC as stated in C101.3, which addresses energy use and conservation, not energy cost.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal would not increase the cost of construction since the proposal is for changes to an exception. If the use of source energy metrics allows more alternatives for achieving energy performance improvements, it may decrease construction costs ultimately.

<tr>
<td></td>
<td>Emittance: 0.90</td>
<td>As proposed</td>
</tr>
</tbody>
</table>

SWHF = Service water heat recovery factor, DWHR = Drain water heat recovery.

a. Where no heating system exists or has been specified, the heating system shall be modeled as fossil fuel. The system characteristics shall be identical in both the standard reference design and proposed design.

b. The ratio between the capacities used in the annual simulations and the capacities determined by sizing runs shall be the same for both the standard reference design and proposed design.

c. Where no cooling system exists or no cooling system has been specified, the cooling system shall be modeled as an air-cooled single-zone system, one unit per thermal zone. The system characteristics shall be identical in both the standard reference design and proposed design.

d. If an economizer is required in accordance with Table C403.5(1) and where no economizer exists or is specified in the proposed design, then a supply-air economizer shall be provided in the standard reference design in accordance with Section C403.5.

e. The SWHF shall be applied as follows:

1. Where potable water from the DWHR unit supplies not less than one shower and not greater than two showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = [1 – (DWHR unit efficiency • 0.36)].

2. Where potable water from the DWHR unit supplies not less than three showers and not greater than four showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = [1 – (DWHR unit efficiency • 0.33)].

3. Where potable water from the DWHR unit supplies not less than five showers and not greater than six showers, of which the drain water from the same showers flows through the DWHR unit, then SWHF = [1 – (DWHR unit efficiency • 0.26)].
Where Items 1 through 3 are not met, SWHF = 1.0.

**Reason:** The purpose of this code change proposal is to improve the efficiency of above-grade walls by eliminating an unnecessary loophole. The current standard reference design assumption for above-grade walls is based on mass walls (where mass walls are proposed) or steel-framed walls (regardless of whether steel or wood-framed walls are proposed). The result is that when a building design incorporates wood-framed walls (which are more efficient than steel-framed walls), the building receives a trade-off credit for the difference in efficiency between the steel and wood framing, even though the choice of framing type may have little or nothing to do with efficiency. While we would prefer a single reference design and related budget, if there are to be different standard reference designs for steel versus mass walls, then logically there should be a different design for wood walls as well.

This proposal applies a more consistent approach that will result in improved efficiency. Whether the wall is mass wall, steel-framed, or wood-framed, the baseline will be the insulation requirement for the corresponding wall type set in the prescriptive table. This will eliminate the trade-off loophole and improve efficiency in most climate zones and occupancy types.

**Cost Impact:** The code change proposal will increase the cost of construction.

This proposal will increase the cost of construction for buildings with wood-framed walls because it will either require additional insulation or the incorporation of other energy efficient measures in Section C407 (to be consistent with the current prescriptive path requirements for wood framing). However, we view this as the elimination of an unnecessary loophole that is applying an incorrect baseline in the simulated performance alternative.

b. The ratio between the capacities used in the annual simulations and the capacities determined by sizing runs shall be the same for both the standard reference design and proposed design.

c. Where no cooling system exists or no cooling system has been specified, the cooling system shall be modeled as an air-cooled single-zone system, one unit per thermal zone. The system characteristics shall be identical in both the standard reference design and proposed design.

d. If an economizer is required in accordance with Table C403.5(1) and where no economizer exists or is specified in the proposed design, then a supply-air economizer shall be provided in the standard reference design in accordance with Section C403.5.

e. The SWHF shall be applied as follows:
   1. Where potable water from the DWHR unit supplies not less than one shower and not greater than two showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = [1 – (DWHR unit efficiency • 0.36)].
   2. Where potable water from the DWHR unit supplies not less than three showers and not greater than four showers, of which the drain water from the same showers flows through the DWHR unit then SWHF = [1 – (DWHR unit efficiency • 0.33)].
   3. Where potable water from the DWHR unit supplies not less than five showers and not greater than six showers, of which the drain water from the same showers flows through the DWHR unit, then SWHF = [1 – (DWHR unit efficiency • 0.26)].
   4. Where Items 1 through 3 are not met, SWHF = 1.0.

Proposal # 4670

CE248-19 Part I
## 2018 International Energy Conservation Code

### TABLE R405.5.2(1) [IRC N1105.2(1)]

**SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS**

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>BUILDING COMPONENT</th>
<th>STANDARD REFERENCE DESIGN</th>
<th>PROPOSED DESIGN</th>
</tr>
</thead>
</table>
| Vertical fenestration other than opaque doors | Total area<sup>h</sup> =  
  (a) The proposed glazing area, where the proposed glazing area is less than 15 percent of the conditioned floor area  
  (b) 15 percent of the conditioned floor area, where the proposed glazing area is 15 percent or more of the conditioned floor area. | As proposed |
|                    | Orientation: equally distributed to four cardinal compass orientations (N, E, S & W). | As proposed |
|                    | U-factor: as specified in Table R402.1.4. | As proposed |
|                    | SHGC: as specified in Table R402.1.2 except for climate zones without an SHGC requirement, the SHGC shall be equal to 0.40. | As proposed |
|                    | Interior shade fraction: 0.92 - (0.21 × SHGC for the standard reference design). | Interior shade fraction: 0.92 - (0.21 × SHGC as proposed) |
|                    | External shading: Automatic and manually controlled shading devices such as blinds or shades are not required to be modeled. | Manual blinds or shades shall be modeled the same as in the standard reference design. Automatically controlled blinds or shades shall be modeled. |
| Skylights | None. Shading: Automatic and manually controlled shading devices such as blinds or shades are not required to be modeled. | As proposed Manual blinds or shades shall be modeled the same as in the standard reference design. Automatically controlled blinds or shades shall be modeled. |

For SI: 1 square foot = 0.93 m<sup>2</sup>, 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m<sup>2</sup>, 1 gallon (US) = 3.785 L,

°C = (°F-32)/1.8, 1 degree = 0.79 rad.

a. Where required by the *code official*, testing shall be conducted by an *approved* party. Hourly
calculations as specified in the ASHRAE *Handbook of Fundamentals*, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[
AF = A_s \times FA \times F
\]

where:

| \(AF\) | Total glazing area. |
| \(A_s\) | Standard reference design total glazing area. |
| \(FA\) | \((\text{Above-grade thermal boundary gross wall area})/(\text{above-grade boundary wall area} + 0.5 \times \text{below-grade boundary wall area})\). |
| \(F\) | \((\text{above-grade thermal boundary wall area})/(\text{above-grade thermal boundary wall area} + \text{common wall area})\) or 0.56, whichever is greater. |

and where:

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.

Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.

Below-grade boundary wall is any thermal boundary wall in soil contact.

Common wall area is the area of walls shared with an adjoining dwelling unit.
$L$ and $CFA$ are in the same units.

**Reason:** The IECC is not currently clear on how manual or automated shades and blinds are to be addressed in the performance path, other than specifying an interior shade fraction. This could lead to potential gaming using different assumptions for shading in the reference and proposed designs, so should be clarified. First, this proposal specifies that manual blinds and shades are to be modeled the same in the reference and proposed designs. This ensures manual shades are treated neutrally, with no credit for manual shades since occupant behavior and the performance of manual controls cannot be guaranteed. Second, it does allow automatically controlled shades to be modeled in the proposed building, as this can provide advanced energy performance without relying on an occupant's behavior. To avoid proprietary issues, the control scheme for how the automated shades are modeled is not specified and is left up to the designer or builder, subject to approval by the code official. This is similar to how automated shades are already addressed in ASHRAE 90.1 for commercial applications, and a similar proposal has been submitted for the commercial IECC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This change simply clarifies how manual and automated blinds and shades are to be addressed in the performance path, and does not impact cost of construction.

Proposal # 4985
CE249-19

IECC: C408.3.1

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code

Revise as follows:

C408.3.1 Functional testing. Prior to passing final inspection, the registered design professional or approved agency shall provide evidence that the lighting control systems have been tested to ensure that control hardware and software are calibrated, adjusted, programmed and in proper working condition in accordance with the construction documents and manufacturer’s instructions. Functional testing shall be in accordance with Sections C408.3.1.1 through C408.3.1.3 for the applicable control type.

Reason: The addition of ‘or approved agency’ will make the lighting systems requirements match the mechanical system requirements in C 408.2.1. This will facilitate and add flexibility to the enforcement of the commissioning requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal does not change the underlying requirements of the Code but simply adds clarifying language that aligns the Lighting Commissioning requirements with those of the mechanical requirements such that a qualified Commissioning professional can perform the Commissioning activities in addition to the previously singularly called out design professional.

Proposal # 4590
CE250-19

IECC: SECTION C501, C501.1, C501.2, C501.4, SECTION C502, C502.1, C502.2, C502.2.1, C502.2.2, C502.2.3, C502.2.6, C502.2.6.1, C502.2.6.2, SECTION C503, C503.1, C503.4, C503.5, C503.6

Proponent: David Collins, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

SECTION C501

GENERAL

Revise as follows:

C501.1 Scope. The provisions of this chapter shall control the alteration, repair, addition and change of occupancy of existing buildings and structures.

C501.2 Existing buildings. Except as specified in this chapter, this code shall not be used to require the removal, alteration or abandonment of, nor prevent the continued use and maintenance of, an existing building or building system lawfully in existence at the time of adoption of this code.

C501.4 Compliance. Alterations, repairs, additions and changes of occupancy to, or relocation of, existing buildings and structures shall comply Sections C502, C503, C504, or C505 of this code, and with the provisions for alterations, repairs, additions and changes of occupancy or relocation, respectively, in this code and in the International Building Code, International Existing Building Code, International Fire Code, International Fuel Gas Code, International Mechanical Code, International Plumbing Code, International Property Maintenance Code, International Private Sewage Disposal Code and NFPA 70. Changes where unconditioned space is changed to conditioned space shall comply with Section C502.

Exception: Additions, alterations, repairs, or changes of occupancy complying with ANSI/ASHRAE/IESNA 90.1

SECTION C502

ADDITIONS

C502.1 General. Additions to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portion of the existing building or building system to comply with this code. Additions shall not create an unsafe or hazardous condition or overload existing building systems. An addition shall be deemed to comply with this code if the addition alone complies or if the existing building and addition comply with this code as a single building.

Additions shall comply with Sections C402, C403, C404, C405 and C502.2. Additions complying with ANSI/ASHRAE/IESNA 90.1 need not comply with Sections C402, C403, C404 and C405.

C503.2 Change in space conditioning. Any nonconditioned or low-energy space that is altered to become conditioned space shall be required to be brought into full compliance with this code. Comply with Section C502.

Exceptions:

1. Where the component performance alternative in Section C402.1.5 is used to comply with this section, the proposed UA shall be not greater than 110 percent of the target UA.
2. Where the total building performance option in Section C407 is used to comply with this section, the annual energy cost of the proposed design shall be not greater than 110 percent of the annual energy cost otherwise permitted by Section C407.3.

C502.3 Prescriptive compliance. Additions shall comply with Sections C502.2 and C502.3.1 through C502.3.6.2.

C502.3.6.2 Prescriptive compliance—Compliance. Additions shall comply in accordance with the following:

New

1. Where an addition has new vertical fenestration area that results in a total building fenestration area less than or equal to that specified in permitted by Section C402.4.1 the addition shall comply with Section C402.1.5, C402.4.3 or C407.

2. Additions with vertical fenestration that result results in a total building fenestration area greater than Section C402.4.1 or additions that exceed the fenestration area greater than that permitted by Section C402.4.1 the fenestration shall comply with Section C402.4.1.1 for the addition only. Additions that result

3. Where an addition has vertical fenestration that results in a total building vertical fenestration area exceeding that specified in permitted by Section C402.4.1.1 the addition shall comply with Section C402.1.5 or C407.

C502.2.2 Skylight area. Skylights shall comply as follows:

1. Where an addition has new skylight area that results in a total building fenestration area less than or equal to that specified in permitted by Section C402.4.1, the addition shall comply with Section C402.1.5 or C407.

2. Additions with new skylight area that result results in a total building skylight area greater than permitted by C402.4.1 or where additions that exceed have skylight area greater than that permitted by C402.4.1, the skylight area shall comply with Section C402.4.1.2 for the addition only.

3. Additions that result Where an addition has skylight area that results in a total building skylight area exceeding that specified in permitted by Section C402.4.1.2, the addition shall comply with Section C402.1.5 or C407.

C502.2.3 Building mechanical systems. New mechanical systems and equipment that are part of the addition and serve the building heating, cooling and ventilation needs shall comply with Section C403, and C408.

C502.2.6 Lighting power and systems. New lighting systems that are installed as part of the addition shall comply with Section C405 and C408.

C502.2.6.1 Interior lighting power. The total interior lighting power for the addition shall comply with Section C405.3.2 for the addition alone, or the existing building and the addition shall comply as a single building.

C502.2.6.2 Exterior lighting power. The total exterior lighting power for the addition shall comply with Section C405.4.2 for the addition alone, or the existing building and the addition shall comply as a single building.

SECTION C503
ALTERATIONS

C503.1 General. Alterations to any building or structure shall comply with the requirements of Section C503 and the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration.
Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems.

Alterations complying with ANSI/ASHRAE/IESNA 90.1 need not comply with Sections C402, C403, C404 and C405.

Exception: The following alterations need not comply with the requirements for new construction, provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Surface-applied window film installed on existing single-pane fenestration assemblies reducing solar heat gain, provided that the code does not require the glazing or fenestration to be replaced.
3. Existing ceiling, wall or floor cavities exposed during construction, provided that these cavities are filled with insulation.
4. Construction where the existing roof, wall or floor cavity is not exposed.
5. Roof recovery.
6. Air barriers shall not be required for roof recovery and roof replacement where the alterations or renovations to the building do not include alterations, renovations or repairs to the remainder of the building envelope.

C503.4 Heating and cooling systems. New heating, cooling and duct systems that are part of the alteration shall comply with Sections C403 and C408.

C503.5 Service hot water systems. New service hot water systems that are part of the alteration shall comply with Section C404, and C408.

C503.6 Lighting systems. New lighting systems that are part of the alteration shall comply with Section C405 and C408.

Exception. Alterations that replace less than 10 percent of the luminaires in a space, provided that such alterations do not increase the installed interior lighting power.

Reason: No technical changes are intended. No advantage to any proprietary interests governed by the code is intended. The intent is strictly to make the IECC more understandable and easier to use. The “Compliance” is relocated from Sec. 501.4 to Sec. 501.2 as more proper code formatting; compliance immediately following scope.

The exception for the 90.1 compliance option applicable to additions and alterations is located under the relocated compliance section

This change clarifies:

- That changes from unconditioned space to condition space must comply as an addition.
- Vertical fenestration and skylight requirements for additions by putting the requirements into a list format for easier reading
- That the IECC and ASHRAE compliance paths cannot be combined.
- That new mechanical, service water, and lighting systems are subject to Section 408 (as per C401.2, requirements for prescriptive and total building performance compliance paths)
“Prescriptive” is stricken from the title of Section 502.2 as it is a misnomer since the section references the performance path as a compliance option.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal does not change the design or construction requirements for a project.

Proposal # 4746
CE251-19
IECC: C502.2.3.1 (New), C502.2.4.1 (New), C502.2.6.3 (New)

Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute
(ericM@newbuildings.org)

2018 International Energy Conservation Code
Add new text as follows:

C502.2.3.1 Mechanical systems acceptance testing. New mechanical systems that serve alterations shall comply with Sections C408.2.2, C408.2.3 and C408.2.5.

Exceptions: The following systems are exempt:

1. Mechanical systems and service water heater systems in buildings where the total mechanical equipment capacity is less than 480,000 Btu/h (140.7 kW) cooling capacity and 600,000 Btu/h (175.8 kW) combined service water-heating and space-heating capacity.
2. Systems included in Section C403.5 that serve individual dwelling units and sleeping units.

C502.2.4.1 Service hot water systems acceptance testing. New service hot water systems that serve additions shall comply with Sections C408.2.3 and C408.2.5.

Exceptions: The following systems are exempt:

1. Service water heater systems in buildings where the total mechanical equipment capacity is less than 600,000 Btu/h (175.8 kW) combined service water-heating and space-heating capacity.
2. Systems included in Section C403.5 that serve individual dwelling units and sleeping units.

C502.2.6.3 Lighting acceptance testing. New lighting systems that serve additions shall comply with Section C408.3.

Reason: Due to the way that the charging language in the IECC is structured, new mechanical, water heating and lighting systems in additions do not need to meet the commissioning / acceptance testing requirements that the same systems in new construction would need to meet. This allows new systems in additions to go without this vital installation step and leaves them vulnerable to poor performance from installation. This proposal closes that loophole.

The proposal includes specific references to the appropriate commissioning /acceptance testing requirements in section C408:

- The balancing (C408.2.2), functional testing (C408.2.3) and documentation (C408.2.5) requirements for HVAC systems.
- The functional testing (C408.2.3) and documentation (C408.2.5) requirements for water heating systems
- The functional testing, documentation and reporting requirements for lighting (C408.3).

It repeats the system-size thresholds in the charging language in C408. The proposal also does not include references to the commissioning plan requirement (C408.2.1) for HVAC equipment. In this way, it has the same scope as the requirements for new construction. Since it references only new equipment in the addition itself, it avoids potentially requiring changes to the existing building systems.
**Cost Impact:** The code change proposal will increase the cost of construction

The proposal will increase the cost of construction. However, these requirements have already been found to be sufficiently cost effective to be included in the code for new construction.
CE252-19

Proponent: Darren Meyers, P.E., IECC LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

C503.1 General. Alterations to any building or structure shall comply with the requirements of Section C503 and the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems. Alterations complying with ANSI/ASHRAE/IESNA 90.1. need not comply with Sections C402, C403, C404 and C405.

Exception: The following alterations need not comply with the requirements for new construction, provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Surface-applied window film installed on existing single-pane fenestration assemblies reducing solar heat gain, provided that the code does not require the glazing or fenestration to be replaced.
3. Existing ceiling, wall or floor cavities exposed during construction, provided that these cavities are filled with insulation.
4. Construction where the existing roof, wall or floor cavity is not exposed.
5. Roof recover.
6. Removal and replacement of a roof membrane where there is existing roof insulation integral to or below the roof deck.
7. Air barriers shall not be required for roof recover and roof replacement where the alterations or renovations to the building do not include alterations, renovations or repairs to the remainder of the building envelope.

Reason: The intent of this proposal is to provide clarity and consistency in the IECC with ASHRAE Standard 90.1-2016, Section 5.1.3, Exception 6.

Bibliography: ASHRAE 90.1—2016: Energy Standard for Buildings Except Low-rise Residential Buildings ... In 2018 IECC Sections ... C401.2, Table C402.1.3, Table C402.1.4, C406.2, Table C407.6.1, C502.1, C503.1, C504.1

Cost Impact: The code change proposal will decrease the cost of construction. This change better positions the IECC to be clearer, more easily applied to removal and replacement operations, and competitive with the 90.1 Standard alternative; thereby no cost impact when compared with current provisions.
2018 International Energy Conservation Code

Revise as follows:

C503.1 General. Alterations to any building or structure shall comply with the requirements of Section C503 and the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems. Alterations complying with ANSI/ASHRAE/IESNA 90.1. need not comply with Sections C402, C403, C404 and C405.

Exception: The following alterations need not comply with the requirements for new construction, provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Surface-applied window film installed on existing single-pane fenestration assemblies reducing solar heat gain, provided that the code does not require the glazing or fenestration to be replaced.
3. Existing ceiling, wall or floor cavities exposed during construction, provided that these cavities are filled with insulation.
4. Construction where the existing roof, wall or floor cavity is not exposed.
5. Roof recover.
6. Air barriers shall not be required for roof recover and roof replacement where the alterations or renovations to the building do not include alterations, renovations or repairs to the remainder of the building envelope.
7. Roof replacements for roof systems less than 2:12 slope shall comply with the low slope roofing insulation requirements for new construction unless the installation of insulation above the structural roof deck necessary to achieve the code required R-value is deemed infeasible by the code official to accommodate the added thickness of insulation above the roof deck. Conditions of infeasibility include but are not limited to flashing height limitations at HVAC, equipment or skylight curbs, low door or glazing heights above the roof surface, parapet, weep holes, drainage patterns or due to cricket or saddle construction, subject to manufacturers installation instructions and code official approval.
CE253-19 Part II
IECC: R503.1.1 (IRC N1109.1.1)

Proponent: William McHugh, The McHugh Company, representing Chicago Roofing Contractors Association (billmchugh-jr@att.net)

2018 International Energy Conservation Code
Revise as follows:

R503.1.1 (IRC N1109.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section R402.1.2 or R402.1.4, Sections R402.2.1 through R402.2.13, R402.3.1, R402.3.2, R402.4.3 and R402.4.5.

Exception: The following alterations shall not be required to comply with the requirements for new construction provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
3. Construction where the existing roof, wall or floor cavity is not exposed.
4. Roof re-cover.
5. Roofs without insulation in the cavity and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing.
6. Surface-applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided that the code does not require the glazing or fenestration assembly to be replaced.
7. Roof replacements for roof systems less than 2:12 slope shall comply with the low slope roofing insulation requirements for new construction unless the installation of insulation above the structural roof deck necessary to achieve the code required R-value is deemed infeasible by the code official to accommodate the added thickness of insulation above the roof deck. Conditions of infeasibility include but are not limited to flashing height limitations at HVAC, equipment or skylight curbs, low door or glazing heights above the roof surface, parapet, weep holes, drainage patterns or due to cricket or saddle construction, subject to manufacturers installation instructions and code official approval.

Reason: The reason for this code proposal is to give code officials that use the International Energy Conservation Code the guidance for when flashing heights are not tall enough to accommodate the use of new construction insulation thicknesses. The IECC’s 503.1 General speaks to the code official, roofing industry and building owner and manager through R503.1 General. Alterations to any building or structure shall comply with the requirements of the code for new construction.

Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as they relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe...
or hazardous condition or overload existing building systems. Alterations shall be such that the existing building or structure does not use more energy than the existing building or structure prior to the alteration. Alterations to existing buildings shall comply with Sections R503.1.1 through R503.2.

This 503.1 General Section, as bolded, clearly states that the building is not to be less conforming than it was before the alteration - it even says it twice. It is especially true of roofing work where the scope of work is to keep the building dry. Just because the insulation is exposed does not mean that the rooftop needs to be rebuilt to accommodate new construction insulation thicknesses.

Cost Impact: The code change proposal will decrease the cost of construction. The code change proposal will decrease the cost of construction. This option, if it becomes part of the IECC, will allow the building owner to not have to raise HVAC units, equipment, roof perimeter nailers, parapet walls, replace doors and windows that are not high enough to accommodate the insulation, stack vents, etc., as would occur on a low sloped residential structure. This action results in cost savings, allowed in the code.

Proposal # 5344
CE254-19

IECC: C503.1

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com); Jack Bailey (jbailey@oneluxstudio.com)

2018 International Energy Conservation Code

Revise as follows:

C503.1 General. Alterations to any building or structure shall comply with the requirements of Section C503, and Sections C402, C403, C404, C405 of the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems. Alterations complying with ANSI/ASHRAE/IESNA 90.1. need not comply with Sections C402, C403, C404 and C405.

Exception: The following alterations need not comply with the requirements for new construction, provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Surface-applied window film installed on existing single-pane fenestration assemblies reducing solar heat gain, provided that the code does not require the glazing or fenestration to be replaced.
3. Existing ceiling, wall or floor cavities exposed during construction, provided that these cavities are filled with insulation.
4. Construction where the existing roof, wall or floor cavity is not exposed.
5. Roof recover.
6. Air barriers shall not be required for roof recover and roof replacement where the alterations or renovations to the building do not include alterations, renovations or repairs to the remainder of the building envelope.

Reason: This revision makes it clear what portions of “the code for new construction” apply to Alterations, and specifically that C406 does not apply to Alterations. We believe that this is the original intent of the code and that this proposal fixes an editorial omission. This change matches the approach already used in C502.1 for Additions. C502.1 does not require compliance with C406.

C406 Additional Efficiency Package Options cannot be required of Additions and Alterations. Most of the options only apply to the construction of new buildings and are not typically possible to achieve for Alteration or Addition projects.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is an editorial clarification.

Proposal # 4596
CE255-19 Part I

PART I — IECC: C202, C503.1
PART II — IECC: R202 (N1101.6), R503.1.1 (IRC N1109.1.1)

Proponent: Bill McHugh, The McHugh Company, representing Chicago Roofing Contractors Association (bill@mc-hugh.us)

2018 International Energy Conservation Code

Add new definition as follows:

**ROOF MEMBRANE PEEL AND REPLACEMENT.** Where an existing roof membrane alone is removed, exposing insulation or sheathing, and only a new weather resisting roof membrane is installed.

Revise as follows:

**C503.1 General.** *Alterations* to any *building* or structure shall comply with the requirements of Section C503 and the code for new construction. *Alterations* shall be such that the existing *building* or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the *alteration*. *Alterations* to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. *Alterations* shall not create an unsafe or hazardous condition or overload existing *building* systems.

*Alterations* complying with ANSI/ASHRAE/IESNA 90.1. need not comply with Sections C402, C403, C404 and C405.

**Exception:** The following *alterations* need not comply with the requirements for new construction, provided that the energy use of the building is not increased:

1. Storm windows installed over existing *fenestration*.
2. Surface-applied window film installed on existing single-pane *fenestration* assemblies reducing solar heat gain, provided that the code does not require the glazing or *fenestration* to be replaced.
3. Existing ceiling, wall or floor cavities exposed during construction, provided that these cavities are filled with insulation.
4. Construction where the existing roof, wall or floor cavity is not exposed.
5. *Roof recover*.
6. *Air barriers* shall not be required for *roof recover* and roof replacement where the *alterations* or renovations to the building do not include *alterations*, renovations or *repairs* to the remainder of the building envelope.
7. *Roof membrane peel and replacement*.

Proposal # 5334
CE255-19 Part II

IECC: R202 (N1101.6), R503.1.1 (IRC N1109.1.1)

Proponent: William McHugh, The McHugh Company, representing Chicago Roofing Contractors Association (billmchugh-jr@att.net)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

ROOF MEMBRANE PEEL AND REPLACEMENT. Where an existing roof membrane alone is removed, exposing insulation or sheathing, and only a new weather resisting roof membrane is installed.

Revise as follows:

R503.1.1 (IRC N1109.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section R402.1.2 or R402.1.4, Sections R402.2.1 through R402.2.13, R402.3.1, R402.3.2, R402.4.3 and R402.4.5.

Exception: The following alterations shall not be required to comply with the requirements for new construction provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
3. Construction where the existing roof, wall or floor cavity is not exposed.
4. Roof re-cover.
5. Roofs without insulation in the cavity and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing.
6. Surface-applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided that the code does not require the glazing or fenestration assembly to be replaced.
7. Roof membrane peel and replacement.

Reason: This new definition and accompanying technical requirement adds a subset of the Roof Recover operation to the International Energy Conservation Code. The operation means that the building owner and manager can re-use the existing insulation providing sustainability to the insulation products in place. The operation provides the building owner and manager with a code approved, economical option that does not increase the energy use of existing buildings, meeting the bolded intent of the 503.1 General Section of the IECC.

For convenience, the C503.1 General section is below, bolded for emphasis:

C503.1 General. Alterations to any building or structure shall comply with the requirements of Section C503 and the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portions of the existing building or...
building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems.

**Cost Impact:** The code change proposal will decrease the cost of construction
The code change proposal will decrease the cost of construction. This type of re-roofing operation is where the roof covering membrane is peeled off, and a new roof covering membrane installed over a prepared surface. This operation is not currently allowed by the International Energy Conservation Code. If allowed, Roof Membrane Peel and Replacement will decrease the cost of construction because the operation does not trigger meeting the minimum R-30 c.i. insulation requirements for new construction, as it would today. The operation does not increase the energy usage of the building, consistent with Section C503.1 General's statements, of the IECC.

Proposal # 5363

CE255-19 Part II
CE256-19
IECC: C503.3.1

Proponent: Darren Meyers, P.E., IECC LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

C503.3.1 Roof replacement. Roof replacements shall comply with Section C402.1.3, C402.1.4, C402.1.5 or C407 where the existing roof assembly is part of the building thermal envelope and contains insulation entirely above the roof deck.

Exception: Where the required R-value cannot be provided due to above-deck thickness limitations presented by existing rooftop conditions, including an HVAC system or refrigeration equipment, skylight curbs, low door or glazing heights, weep holes, parapet or roof flashing heights, the maximum approved thickness of insulation compatible with the available space and existing uses shall be installed.

Reason: This proposal is CE287-16 resubmitted with the sole difference clarifying “above-deck” thickness and adding “approved.” CE287-16 received a Committee recommendation of “Disapproval,” a Public Comment recommendation of “As Modified by Public Comment” (AMPC), but ultimately did not receive the two-thirds necessary to prevail during the “Online Governmental Consensus Vote” (OGCV), leading to “Disapproval” as its Final Action.

Specifically, the newly proposed exception addresses the AMPC and the challenge of constructability when installing additional roof insulation in reroofing situations including roof recover and roof replacement where existing conditions do not allow for the full thickness of insulation required by Table C402.1.3 or Table C402.1.4. Consider the sheer square footage of buildings constructed before an adoption of the 2009 IECC, that now require reroofing, without adequate “clear space” to accommodate up to 5+ inches (R-25-ish) or 6+ inches (R-30-ish) of insulation as the IECC evolved thru 2012 to 2015 and now the 2018 Editions. The building stock now considered 10 to 20 to 30+ years old, is far more likely to avail itself of skylight and structural curb heights, scupper and sump depths, door and window access thresholds that would turn into ponds, if five to six inches of insulation were "retroactively" foisted upon building ownership.

Moreover, if the IECC CDC were to consult the premise to Section C505.1, that "[neither] an increase in demand for either fossil fuel [nor] electrical energy shall comply with this code," so long as the current level of insulation in the roof is replaced with an equivalent thickness/level/R-value of NEW! insulation product, you’d likely conclude that he newly proposed Exception is a "do-no-harm" proposition.

The proposed exception is a pragmatic and constructible solution taken nearly word-for-word from the 2015 IgCC, Section 1003.2.7—Roof Replacement Insulation. We believe the proposal makes clear that the maximum thickness of insulation compatible within the technically-feasible limitations of available space is installed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This change better positions the IECC to be clearer, more easily applied to reroofing, more competitive than the 90.1 Standard alternative on this issue; thereby no cost impact when compared with current provisions.

Proposal # 5296

CE256-19
CE257-19

IECC: SECTION C503, C503.3.1

Proponent: Wanda Edwards, Wanda Edwards Consulting, Inc., representing RCI, Inc. (wedwards@rci-online.org)

2018 International Energy Conservation Code

SECTION C503
ALTERATIONS

Revise as follows:

C503.3.1 Roof replacement. Roof replacements shall comply with Section C402.1.3, C402.1.4, C402.1.5 or C407 where the existing roof assembly is part of the building thermal envelope and contains insulation entirely above the roof deck.

Exception: Where approved by the code official, the required R-value cannot be provided because of the thickness limitations presented by existing rooftop conditions, including heating, ventilating and air conditioning equipment, low door or glazing heights, parapet heights and roof flashing heights, the maximum thickness of insulation compatible with the available space and existing uses shall be installed.

Reason: Occasionally, the installation of additional insulation can be technically infeasible. For instance, adding insulation can block windows on adjacent walls, entrances on and off the roof can have the height of the opening lessened by adding insulation. Take for an example an existing roof with internal drainage system. If the drains are 60 feet apart, the maximum depth of insulation with be 30 feet from the drain. If the insulation slopes at the minimum required slope of 1/4 inch per foot, the insulation depth with be 7.5 inches thirty feet from the drain. This proposal would require that the code official confirm that the addition of the insulation is technically infeasible to ensure this provision is utilized only when approved by the code official, and not when the contractor or designer determines it technically infeasible and ensure the provision is used properly.

Cost Impact: The code change proposal will decrease the cost of construction
This proposal would decrease the cost of construction when it is determined that it is technically infeasible to add insulation above the roof deck.

Proposal # 5591
Proponent: David Renn, PE, SE, City and County of Denver, representing Code Change Committee of Colorado Chapter of ICC (david.renn@denvergov.org)

2018 International Energy Conservation Code

Revise as follows:

C503.3.1 Roof replacement. Roof replacements shall comply with Section C402.1.3, C402.1.4, C402.1.5 or C407 where the existing roof assembly is part of the building thermal envelope and contains insulation entirely above the roof deck. In no case shall the R-value of the roof insulation be reduced or the U-factor of the roof assembly be increased as part of the roof replacement.

Reason: Where roof replacements must comply with thermal envelope requirements of new construction, the code currently allows the use of one of 4 different compliance methods. Depending on the compliance method used, it may not be compatible with the original design of the building thermal envelope and may actually allow a reduction in roof insulation. For example, if a building was designed using the Total Building Performance method (C407), the roof insulation may have been increased to be above prescriptive requirements to allow less insulation in the walls. A roof replacement could then use the prescriptive requirements (C402.1.3 or C402.1.4) of the current code, which may require less insulation than the original design. To eliminate the potential of a reduction in performance of the entire thermal envelope, this proposal requires that the roof insulation not be reduced during a roof replacement, even if a different compliance path is used.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal fixes a potential loophole in the current code that rarely would occur, so cost of construction would typically not increase or decrease. There would be a cost of construction increase if the current loophole was used to reduce the amount of insulation that is provided in a roof replacement, but likeliness of this occurring is rare.
CE259-19

IECC: C503.3.2, C401.2.1

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

C503.3.2 Vertical fenestration. The addition of vertical fenestration that results in a total building fenestration area less than or equal to that specified in Section C402.4.1 shall comply with Section C402.1.5, C402.4.3 or C407. The addition of vertical fenestration that results in a total building fenestration area greater than Section C402.4.1 shall comply with Section C402.4.1.1 for the space adjacent to the new fenestration only. Alterations that result in a total building vertical fenestration area exceeding that specified in Section C402.4.1.1 shall comply with Section C402.1.5 or C407. Provided that the vertical fenestration area is not changed, using the same vertical fenestration area in the standard reference design as the building prior to alteration shall be an alternative to using the vertical fenestration area specified in Table C407.5.1(1).

C401.2.1 C503.3.2.1 Application to replacement Replacement fenestration products. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for U-factor and SHGC in Table C402.4.

Exception: An area-weighted average of the U-factor of replacement fenestration products being installed in the building for each fenestration product category listed in Table C402.4 shall be permitted to satisfy the U-factor requirements for each fenestration product category listed in Table C402.4. Individual fenestration products from different product categories listed in Table C402.4 shall not be combined in calculating the area-weighted average U-factor.

Reason: Moving fenestration replacement to Chapter 5 properly co-locates the provisions for fenestration changes in existing buildings.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change does not increase or decrease code provisions nor impact construction methods. It clarifies language and provisions already contained in the code

Proposal # 4176
Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute (ericM@newbuildings.org)

2018 International Energy Conservation Code

Add new text as follows:

**C503.4.2 Mechanical system acceptance testing.** New mechanical systems that serve alterations shall comply with Sections C408.2.2, C408.2.3 and C408.2.5.

Exceptions:

1. Mechanical systems and service water heater systems in buildings where the total mechanical equipment capacity is less than 480,000 Btu/h (140.7 kW) cooling capacity and 600,000 Btu/h (175.8 kW) combined service water-heating and space-heating capacity.
2. Systems included in Section C403.5 that serve individual dwelling units and sleeping units.

**C503.5.1 Service hot water system acceptance testing.** New service hot water systems that serve alterations shall comply with Sections C408.2.3 and C408.2.5.

Exceptions:

1. Service water heater systems in buildings where the total mechanical equipment capacity is less than 600,000 Btu/h (175.8 kW) combined service water-heating and space-heating capacity.
2. Systems included in Section C403.5 that serve individual dwelling units and sleeping units.

**C503.6.1 Lighting acceptance testing.** New lighting systems that serve alterations shall comply with Section C408.3.

Reason: Due to the way that the charging language in the IECC is structured, new mechanical, water heating and lighting systems in alterations do not need to meet the commissioning / acceptance testing requirements that the same systems in new construction would need to meet. This allows new systems in alterations to go without this vital installation step and leaves them vulnerable to poor performance from installation. This proposal closes that loophole.

The proposal includes specific references to the appropriate commissioning /acceptance testing requirements in section C408:

- The balancing (C408.2.2), functional testing (C408.2.3) and documentation (C408.2.5) requirements for HVAC systems.
- The functional testing (C408.2.3) and documentation (C408.2.5) requirements for water heating systems
- The functional testing, documentation and reporting requirements for lighting (C408.3).

It repeats the system-size thresholds in the charging language in C408. In this way, it has the same scope as the requirements for new construction. Since it references only new equipment in alterations, it avoids potentially requiring changes to the existing building systems. The proposal does not include references to the commissioning plan requirement (C408.2.1) for HVAC equipment.
Cost Impact: The code change proposal will increase the cost of construction. The proposal will increase the cost of construction. However, these requirements have already been found to be sufficiently cost effective to be included in the code for new construction.
2018 International Energy Conservation Code

Add new definition as follows:

ENERGY USE INTENSITY (EUI). The metric indicating the total amount of energy consumed by a building in one year divided by the total gross floor area of the building.

SECTION C505
CHANGE OF OCCUPANCY OR USE

C505.1 General. Spaces undergoing a change in occupancy that would result in an increase in demand for either fossil fuel or electrical energy shall comply with this code. Where the use in a space changes from one use in Table C405.3.2(1) or C405.3.2(2) to another use in Table C405.3.2(1) or C405.3.2(2), the installed lighting wattage shall comply with Section C405.3. Where the space undergoing a change in occupancy or use is in a building with a fenestration area that exceeds the limitations of Section C402.4.1, the space is exempt from Section C402.4.1 provided that there is not an increase in fenestration area.

Exceptions:

from F, H or U occupancy classification shall comply with Section C503. Buildings or portions of buildings undergoing a change of occupancy without alterations shall comply with Section C502.2

Exceptions:

1. Where the component performance alternative in Section C402.1.5 is used to comply with this section, the proposed UA shall be not greater than 110 percent of the target UA.
2. Where the total building performance option in Section C407 is used to comply with this section, the annual energy cost of the proposed design shall be not greater than 110 percent of the annual energy cost otherwise permitted by Section C407.3.

Add new text as follows:

C505.1.1 Alterations and change of occupancy Alterations made concurrently with any change of occupancy shall be in accordance with Section C503.

C505.1.2 Portions of buildings Where changes in occupancy and use are made to portions of an existing building, only those portions of the building shall comply with Section C505.2.

C505.2 Energy Use Intensities Building envelope, space heating, cooling, ventilation, lighting and service water heating shall comply with Sections C505.2.1 through C505.2.4.

Exceptions:

1. Where it is demonstrated by analysis approved by the code official that the change will not increase energy
2. Where the occupancy or use change is less than 5,000 square feet in area.

**C505.2.1 Building Envelope** Where a change of occupancy or use is made to a whole building that exceeds the maximum fenestration area allowed by Section C402.4.1, the building shall comply with Section C402.1.5, with a proposed UA that shall not be greater than 110 percent of the target UA.

**Exception:**

Where the change of occupancy or use is made to a portion of the building, the new occupancy is exempt from Section C402.4.1 provided that there is not an increase in fenestration area.

**C505.2.2 Building Mechanical Systems** Where a change of occupancy or use results in the same or increased energy use intensity rank as specified in Table C505.2.2, the systems serving the building or space undergoing the change shall comply with Section C403.

**C505.2.3 Service Water Heating** Where a change of occupancy or use results in the same or increased energy use intensity rank as specified in Table C505.2.3, the service water heating systems serving the building or space undergoing the change shall comply with Section C404.

**C505.2.4 Lighting** Where a change of occupancy or use results in the same or increased energy use intensity rank as specified in Table C505.2.4, the lighting systems serving the building or space undergoing the change shall comply with Section C405 except for Sections C405.2.6 and C405.4.

Reason: The IECC 2018 change of occupancy requirement (C505.1) begins with this statement: “Spaces undergoing a change in occupancy that would result in an increase in demand for either fossil fuel or electrical energy shall comply with this code.”

Field research and surveys of building officials demonstrate that this requirement is difficult to enforce (Clinton et al, 2016). One reason for this is that while it is a clear performance requirement, there is no simple compliance evaluation method other than energy modeling, which is beyond the capabilities of most change-of-occupancy permit applicants. As depicted in the referenced survey findings and community-based pilot research, building officials often require energy efficiency equipment upgrades, such as lighting or HVAC, in buildings undergoing a change of occupancy. This proposal seeks to provide clarity to that approach by providing a simple breakdown of energy use intensity (EUI) by building occupancy type and system type.

The proposed code change draws on a tradition of rehabilitation “smart codes” use-based lookup tables, is more consistent with the intent of the IECC, presents no cost increase, and incorporates extensive research and stakeholder input.

This proposal advances the Energy Use Intensity (EUI) as the metric for energy demand and the trigger for code compliance. Historic energy intensity per square foot is recorded for commercial buildings in the Commercial Buildings Energy Consumption Survey (CBECS). The CBECS data make it possible to rank building occupancies in the order of the energy intensities. Note that the ranking of occupancies to trigger specific code requirements has been a feature of the International Existing Building Code (IEBC) since its earliest editions (see IEBC 2009 Section 912, Change of Occupancy Classification, Tables 912.4, 912.5 and 912.6), and thus is familiar to building code officials.

Energy intensity data in CBECS is further broken down by various end uses (space conditioning, service water heating and lighting) which makes it possible to identify when it is appropriate to trigger code compliance of specific sections of the IECC. For each of these end uses, an increase in intensity triggers compliance with the correlating code provisions related to new construction in Chapter 4. Only an increase in energy intensities in all three of the end uses triggers full compliance with the code.

There are two exceptions that apply to all four end uses, indicated in Section C505.2:

1. Where it is demonstrated by analysis approved by the code official that the change will not increase energy use intensity.

2. Where the occupancy or use change is less than 5,000 square feet in area.

A matrix has been developed for each system end use that groups building occupancy classifications into HIGH, MEDIUM and LOW energy use intensities, measured in annual kBTU/sf. Data for this analysis came from the
U.S. Department of Energy’s 2012 CBECS. When occupancy classification or use is being changed from one energy intensity rank to a higher energy use intensity rank (or remains within the same energy use intensity rank), this proposal requires that specific system end-use to comply with the code.

### Change of Occupancy Scale - Space Heating, Cooling and Ventilation

</tr>
</tbody>
</table>

Occupancy classifications F, H and U are typically not designed primarily for occupant comfort, and are generally classified as low energy use intensity buildings. Thus any change from one of these groups to any other should be required to comply with the provisions under Section C503 Alterations, even if no physical alteration is planned.

Section C505.2.1 Building Envelope is included as a building system, although with different criteria than EUI Intensity. The requirement and exception exist in the 2018 language; they are simply relocated in this proposal.

This code change proposal has been developed with support from the Consortium for Building Energy Innovation (CBEI), a project of the U. S. Department of Energy, and research conducted by Rutgers University.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. The current code requirements trigger full compliance with the code when there is an increase in energy demand. The proposed code change offers the metric of energy use intensity per square foot per year for measuring energy demand by occupancy. It applies this metric separately to three energy end uses: space conditioning, lighting, and water heating. Therefore, compliance with the code is triggered only for the end uses for which energy intensity is increased.

In most cases, the proposed change triggers partial code compliance, and only rarely will it trigger full code compliance.
2018 International Energy Conservation Code

Revise as follows:

CA103.6 Interconnection pathway. Construction documents shall indicate pathways for routing of conduit or piping from the solar-ready zone to the electrical service panel and electrical energy storage system area, or service hot water system.

Add new text as follows:

CA103.7 Electrical energy storage system-ready area. The floor area of the electrical energy storage system-ready area shall be not less than 2 feet in one dimension and 4 feet in another dimension, and located in accordance with Section 1206.2.8 of the International Fire Code. The location and layout diagram of the electrical energy storage system-ready area shall be indicated on the construction documents.

Revise as follows:

CA103.8 Electrical service reserved space. The main electrical service panel shall have a reserved space to allow installation of a dual-pole circuit breaker for future solar electric installation and a dual-pole circuit breaker for future electrical energy storage system installation. These spaces shall be labeled “For Future Solar Electric and Storage.” The reserved space spaces shall be positioned at the end of the panel that is opposite from the panel supply conductor connection.

Reason: Appendix CA in IECC-commercial and Appendix RB in IECC-residential have proven useful for jurisdictions seeking to add solar ready provisions to state or local codes. As many jurisdictions in which the appendices are being considered are also facing current or future constraints on electric grid capacity to accommodate existing and new distributed solar generation resources, policy objectives are emerging to support the storage of energy produced by solar panels and shift its temporal impact on the grid. This proposal modifies Appendix CA provisions to ensure that there is design and space consideration for a standard sized battery rack, and for the connections to the electrical panels. As with the rationale for solar-ready, it is generally much more cost-effective at the time of new construction to design for future installation of this equipment than it is to retrofit later in the building’s life.

The proposed language also cites the IFC to ensure there is sufficient clearance around the battery rack to meet life/safety concerns. The IFC is already referenced in Chapter 6.

Cost Impact: The code change proposal will increase the cost of construction.

The cost impacts are limited to additional design professional fees, to markings on the panels, and to additional construction costs only if there were not spare square footage available in the equipment or storage rooms where panels are generally located. In that case, it would be equal to the construction costs for an additional 8 square feet of storage space.

Proposal # 4965
Appendix CB
SOLAR PHOTOVOLTAIC (PV) SYSTEM REQUIRED - COMMERCIAL

SECTION CB101
SCOPE

CB101.1 General. These provisions shall be applicable for newly constructed commercial buildings, or additions larger than 5,000 square feet of gross conditioned floor area to commercial buildings, where solar photovoltaic (PV) systems are required.

SECTION CB102
DEFINITIONS

CB102.1 General. The following words and terms shall, for the purposes of this appendix, have the meanings shown herein. Refer to Chapter 2 for general definitions.

Add new text as follows:

COMMUNITY SOLAR FACILITY. A facility that generates electrical energy with a solar photovoltaic system, is qualified as a community energy facility, and allocates bill credits to customers under state and local utility statutes and rules.

SECTION CB103
SOLAR PHOTOVOLTAIC (PV) SYSTEMS

CB103.1 Renewable energy systems. Newly constructed commercial buildings, or additions larger than 5,000 square feet of gross conditioned floor area to commercial buildings, shall have an on-site solar photovoltaic system installed. Photovoltaic (PV) systems shall comply with Sections CB103.2 through CB103.4. The code official is authorized to exempt a covered building from the on-site photovoltaic system requirement or allow an alternative means of compliance under any of the following conditions:

Exceptions:
1. Where the code official determines the building has satisfied the purpose and intent of this provision through the use of alternative on-site renewable energy systems such as wind energy systems.

2. Where the code official determines an on-site or off-site community solar facility is dedicated to the building with a legally binding and executed agreement, in conformance with Section CB103.3.

**CB103.2 Photovoltaic (PV) system sizing requirement.** Minimum installed capacity of PV systems shall be determined in accordance with this section. The PV system installed nameplate capacity (kWdc) shall be not less than 0.25 times the conditioned floor area (0.25 Wdc per square foot). The nameplate PV system size shall be calculated as the sum of each PV module's nameplate output (Wdc). For buildings 4 or more stories in height, the conditioned floor area for this calculation shall be based on the largest 3 above-grade stories in the building. Where the on-site renewable energy option in Section C406 is selected, the minimum installed capacity required in this section shall be in addition to that required by Section C406.

**CB103.3. Community solar facility** Where a community solar facility is used as an alternative to an on-site photovoltaic system, the community solar facility shall provide energy savings benefits directly to the building that would otherwise have been required to have an on-site photovoltaic system. The energy savings benefits shall be allocated from the total resource of the community solar facility in a manner demonstrated to be equivalent to the reductions in energy consumption that would have resulted from the on-site photovoltaic system that is otherwise required. The community solar facility shall provide the required energy savings benefits to the dedicated building for a period not less than twenty years. The energy savings benefits shall not be attributed to other purposes and shall not be transferred to other buildings or property.

**CB103.4 Leases and power purchase agreements.** On-site photovoltaic systems that are leased by the end-use customer (tenant or owner) or that supply electricity to the end-use customer through a power purchase agreement (PPA) shall be permitted to satisfy the requirement provided the system meets all other requirement criteria.

Proposal # 5658
Appendix RB
SOLAR PHOTOVOLTAIC (PV) SYSTEM REQUIRED

SECTION RB101
SCOPE

RB101.1 General. These provisions shall be applicable for newly constructed residential buildings where solar photovoltaic (PV) systems are required.

SECTION RB102
DEFINITIONS

RB102.1 General. The following words and terms shall, for the purposes of this appendix, have the meanings shown herein. Refer to Chapter 2 for general definitions.

Add new definition as follows:

COMMUNITY SOLAR FACILITY. A facility that generates electrical energy with a solar photovoltaic system, is qualified as a community energy facility, and allocates bill credits to customers, under state and local utility statutes and rules.

STEEP SLOPE. A roof slope greater than two units vertical in 12 units horizontal (17-percent slope).

Add new text as follows:

SECTION RB103
SOLAR PHOTOVOLTAIC SYSTEM

RB103.1 Renewable energy systems. Newly constructed residential buildings shall have an on-site solar photovoltaic (PV) system installed. Photovoltaic systems shall comply with Sections RB103.2 through RB103.6. The code official is authorized to exempt a covered building from the on-site photovoltaic system requirement or allow an alternative means of compliance under any of the following conditions:

Exceptions:

1. Where the code official determines there are practical challenges that cause satisfaction of the requirements to be infeasible. Practical challenges include, but are not limited to, building site location, limited rooftop availability, or shading from nearby structures, topography, or vegetation.

2. Where the code official determines the purpose and intent of this provision is satisfied through the use of alternative on-site renewable energy systems such as wind energy systems.
3. If the code official determines an on-site or off-site community solar facility is dedicated to the building with a legally binding and executed agreement, and is in conformance with Section RB103.5.

**RB103.2 Photovoltaic (PV) system sizing requirement.** Minimum installed capacity of PV systems shall be determined by using one of the two methods in this section, either prescriptive PV sizing in Section RB103.2.1 or performance PV sizing in Section RB103.2.2. Buildings with conditioned floor area of 4,500 square feet or greater shall use the performance PV sizing approach in Section RB103.2.2.

**RB103.2.1 Prescriptive PV sizing method.** For the prescriptive PV sizing method, the PV system installed nameplate capacity (kW\textsubscript{DC}) shall be not less than 1.0 times the conditioned floor area (1.0 Watts per square foot). The nameplate PV system size shall be calculated as the sum of each PV module's nameplate output (W\textsubscript{DC}).

**RB103.2.2 Performance PV sizing method.** For the performance PV sizing method, the PV system shall be sized to meet at least 75 percent of the building's total electrical energy use on an annual basis, including both conditioned and unconditioned space. The minimum PV system size requirement (kW\textsubscript{DC}) shall be calculated using modeling software or other methods approved by the code official.

**RB103.3 Photovoltaic system orientation.** Fixed-orientation photovoltaic systems located on steep sloped roofs shall be oriented with azimuth of each array between 90 degrees and 300 degrees measured clockwise from true north.

**Exception:** Photovoltaic systems with one or more arrays oriented outside the prescribed azimuth range when the PV system is modeled using performance PV sizing method in Section RB103.2.2.

**RB103.4 Shading.** All PV systems shall be designed to meet minimal shading criterion in Section RB103.4.1 or the detailed geometries of PV arrays and obstructions shall be considered in the performance PV sizing method in conformance with Section RB103.4.2.

**RB103.4.1 Minimal shading criterion.** To comply with minimal shading criterion, a PV array shall be no closer to any shading obstruction than twice the height of the obstruction above the PV array. All obstructions that project above the point on the PV array that is closest to the obstruction shall meet this criterion for the array to be considered minimally shaded.

**Exception:** Any obstruction located north of all points on the array need not be considered as a shading obstruction...

**RB103.4.2 Solar access verification.** Where any PV array does not meet the minimal shading criterion of Section RB103.4.1, detailed geometries of the PV array and shading profiles from obstructions shall be considered in the performance PV sizing method. Shading profiles shall be measured with a solar assessment tool or determined from aerial satellite images or other automated resources approved by the code official.

**RB103.5 Community solar facility.** Where a community solar facility is used as an alternative to an on-site photovoltaic system, the community solar facility shall provide energy savings benefits directly to the building that would otherwise have been required to have an on-site photovoltaic system. The energy savings benefits shall be allocated from the total resource of the community solar facility in a manner demonstrated to be equivalent to the reductions in energy consumption that would have resulted from the on-site photovoltaic system that is otherwise required. The community solar facility shall provide the required energy savings benefits to the dedicated building for a period not less than twenty years. The energy savings benefits shall not be attributed to other purposes and shall not be transferred to other buildings or property.

**SECTION RB104**
RB104.1 Leases and power purchase agreements. On-site photovoltaic systems that are leased by the end-use customer (tenant or owner) or that supply electricity to the end-use customer through a power purchase agreement (PPA) shall be permitted to satisfy the requirement provided the system meets all other requirement criteria.

Proposal # 5649

CE263-19 Part II
2018 International Residential Code

Add new text as follows:

Appendix U

SOLAR PHOTOVOLTAIC (PV) SYSTEM REQUIRED

SECTION AU101

SCOPE

AU101.1 General. These provisions shall be applicable for newly constructed residential buildings where solar photovoltaic (PV) systems are required.

SECTION AU102

DEFINITIONS

AU102.1 General. The following words and terms shall, for the purposes of this appendix, have the meanings shown herein. Refer to Chapter 2 for general definitions.

Add new definition as follows:

COMMUNITY SOLAR FACILITY. A facility that generates electrical energy with a solar photovoltaic system, is qualified as a community energy facility, and allocates bill credits to customers, under state and local utility statutes and rules.

STEEP SLOPE. A roof slope greater than two units vertical in 12 units horizontal (17-percent slope).

Add new text as follows:

SECTION AU103

SOLAR PHOTOVOLTAIC SYSTEM

RB103.1 Renewable energy systems. Newly constructed residential buildings shall have an on-site solar photovoltaic (PV) system installed. Photovoltaic systems shall comply with Sections AU103.2 through AU103.6. The code official is authorized to exempt a covered building from the on-site photovoltaic system requirement or allow an alternative means of compliance under any of the following conditions:

Exceptions:

1. Where the code official determines there are practical challenges that cause satisfaction of the requirements to be infeasible. Practical challenges include, but are not limited to, building site location, limited rooftop availability, or shading from nearby structures, topography, or vegetation.

2. Where the code official determines the purpose and intent of this provision is satisfied through the use of alternative on-site renewable energy systems such as wind energy systems.
3. If the code official determines an on-site or off-site community solar facility is dedicated to the building with a legally binding and executed agreement, and is in conformance with Section AU103.5.

**AU103.2 Photovoltaic (PV) system sizing requirement.** Minimum installed capacity of PV systems shall be determined by using one of the two methods in this section, either prescriptive PV sizing in Section AU103.2.1 or performance PV sizing in Section AU103.2.2. Buildings with conditioned floor area of 4,500 square feet or greater shall use the performance PV sizing approach in Section AU103.2.2.

**AU103.2.1 Prescriptive PV sizing method.** For the prescriptive PV sizing method, the PV system installed nameplate capacity \((\text{kW}_{\text{DC}})\) shall be not less than 1.0 times the conditioned floor area \((1.0 \text{ Watts per square foot})\). The nameplate PV system size shall be calculated as the sum of each PV module’s nameplate output \((\text{W}_{\text{DC}})\).

**AU103.2.2 Performance PV sizing method.** For the performance PV sizing method, the PV system shall be sized to meet at least 75 percent of the building's total electrical energy use on an annual basis, including both conditioned and unconditioned space. The minimum PV system size requirement \((\text{kW}_{\text{DC}})\) shall be calculated using modeling software or other methods approved by the code official.

**AU103.3 Photovoltaic system orientation.** Fixed-orientation photovoltaic systems located on steep sloped roofs shall be oriented with azimuth of each array between 90 degrees and 300 degrees measured clockwise from true north.

**Exception:** Photovoltaic systems with one or more arrays oriented outside the prescribed azimuth range when the PV system is modeled using performance PV sizing method in Section AU103.2.2.

**AU103.4 Shading.** All PV systems shall be designed to meet minimal shading criterion in Section AU103.4.1 or the detailed geometries of PV arrays and obstructions shall be considered in the performance PV sizing method in conformance with Section AU103.4.2.

**AU103.4.1 Minimal shading criterion.** To comply with minimal shading criterion, a PV array shall be no closer to any shading obstruction than twice the height of the obstruction above the PV array. All obstructions that project above the point on the PV array that is closest to the obstruction shall meet this criterion for the array to be considered minimally shaded.

**Exception:** Any obstruction located north of all points on the array need not be considered as a shading obstruction.

**AU103.4.2 Solar access verification.** Where any PV array does not meet the minimal shading criterion of Section AU103.4.1, detailed geometries of the PV array and shading profiles from obstructions shall be considered in the performance PV sizing method. Shading profiles shall be measured with a solar assessment tool or determined from aerial satellite images or other automated resources approved by the code official.

**AU103.5 Community solar facility.** Where a community solar facility is used as an alternative to an on-site photovoltaic system, the community solar facility shall provide energy savings benefits directly to the building that would otherwise have been required to have an on-site photovoltaic system. The energy savings benefits shall be allocated from the total resource of the community solar facility in a manner demonstrated to be equivalent to the reductions in energy consumption that would have resulted from the on-site photovoltaic system that is otherwise required. The community solar facility shall provide the required energy savings benefits to the dedicated building for a period not less than twenty years. The energy savings benefits shall not be attributed to other purposes and shall not be transferred to other buildings or property.

**SECTION AU104**
AU104.1 Leases and power purchase agreements. On-site photovoltaic systems that are leased by the end-use customer (tenant or owner) or that supply electricity to the end-use customer through a power purchase agreement (PPA) shall be permitted to satisfy the requirement provided the system meets all other requirement criteria.

Reason: This proposal provides a new Appendix for the International Residential Code which would be available to jurisdictions wanting to adopt renewable energy requirements for new one- and two family dwellings and townhouse buildings; enabling direct opportunity to meet state RPS goals to incorporate renewable energy. This proposal continues to move renewable energy into mainstream practice for the design and construction industries which will diversify the state and jurisdictional energy portfolio amongst traditional energy resources and new renewable generation via utilities and distributed energy resources. The benefit to the homeowner is lower, more consistent energy bills. This language does not increase enforcement efforts because the review and inspection process for mechanical and renewable energy systems is currently standard practice. This proposal is modeled after the California Energy Commission (CEC) model ordinance language, which is useful to early adopters that want to require PV for new residential buildings in their communities, with modification to allow jurisdictions flexibility to further customize.

Individual technical provisions of this appendix are also based on 2019 CA Building Energy Efficiency Standards (BEES):

Joint Appendix JA11 -- Qualification Requirements for Photovoltaic System, and

Section 10-115 -- Community Shared Solar Electric Generation System or Community Shared Battery Storage System Compliance Option for Onsite Solar Electric Generation or Battery Storage Requirements.

Cost Impact: The code change proposal will increase the cost of construction
This proposal will increase the first cost of construction for PV systems that are a cash purchase, but not for systems that are under lease agreements or power purchase agreements (PPA's). The installed cost of new PV systems retrofitted on existing homes is approximately $2.50 per Watt. Greater cost savings can be realized owing to installations on new homes and the efficiencies of repetitive procedures.

Proposal # 5808

CE263-19 Part III
Add new text as follows:

**AX 100**

**ZERO CODE RENEWABLE ENERGY STANDARD**

**AX101 PURPOSE** The purpose of the Zero Code Renewable Energy Appendix is to supplement the International Energy Conservation Code and require renewable energy systems of adequate capacity to achieve zero-net-carbon.

**AX102 SCOPE** This appendix applies to new buildings that are addressed by the International Energy Conservation Code.

**Exceptions:**

1. Single-family houses, multifamily structures of three stories or fewer above grade in height, manufactured homes (mobile homes), and manufactured houses (modular).
2. Buildings that use neither electricity nor fossil fuel.

**AX103 Definitions** The following definitions supplement or modify the definitions in the International Energy Conservation Code.

**ADJUSTED OFF-SITE RENEWABLE ENERGY.** The amount of energy production from off-site renewable energy systems that may be used to offset building energy.

**BUILDING ENERGY.** All energy consumed at the building site as measured at the site boundary. Contributions from on-site or off-site renewable energy systems shall not be considered when determining the building energy.

**ENERGY UTILIZATION INTENSITY (EUI).** The site energy for either the baseline building or the proposed building divided by the gross conditioned floor area plus any semi-heated floor area of the building. For the baseline building, the EUI can be divided between regulated energy use and unregulated energy use.

**RENEWABLE ENERGY SYSTEM.** Photovoltaic, solar thermal, geothermal energy, and wind systems used to generate energy.

**ON-SITE RENEWABLE ENERGY SYSTEM.** Renewable energy systems on the building project.

**OFF-SITE RENEWABLE ENERGY SYSTEM.** Renewable energy system not located on the building project.

**ZERO ENERGY PERFORMANCE INDEX (ZEPI_{PB,EF}).** The ratio of the proposed building EUI without renewables to the baseline building EUI, expressed as a percentage.
SEMI-HEATED SPACE. An enclosed space within a building that is heated by a heating system whose output capacity is greater than or equal to 3.4 Btu/h*ft² of floor area but is not a conditioned space.

AX104 Minimum renewable energy  On-site renewable energy systems shall be installed or off-site renewable energy shall be procured to offset the building energy.

\[
\text{RE}_{\text{onsite}} + \text{RE}_{\text{offsite}} \geq E_{\text{building}}
\]

where

\[\text{RE}_{\text{onsite}} = \text{annual site energy production from on-site renewable energy systems (see Section AX104.2)}\]

\[\text{RE}_{\text{offsite}} = \text{adjusted annual site energy production from off-site renewable energy systems that may be credited against building energy use (see Section AX104.3)}\]

\[E_{\text{building}} = \text{building energy use without consideration of renewable energy systems.}\]

When Section C401.2 (2) is used for compliance with the International Energy Conservation Code, building energy shall be determined by multiplying the gross conditioned floor area plus the gross semi-heated floor area of the proposed building by an EUI selected from Table AX104.1. Use a weighted average for mixed-use buildings.

When Section C401.2 (1) or C401.2 (3) is used for compliance with the International Energy Conservation Code, building energy shall be determined from energy simulations.

**AX104.1 Calculation of On-Site Renewable Energy** The annual energy production from on-site renewable energy systems shall be determined using the PVWatts software or other software approved by the code official.

**AX104.2 Off-Site Renewable Energy** Off-site energy shall comply with Sections AX104.2.1 and AX104.2.2
AX104.2.1 Qualifying off-site procurement methods. The following are considered qualifying off-site renewable energy procurement methods:

1. Community Renewables: an offsite renewable energy system for which the owner has purchased or leased renewable energy capacity along with other subscribers.
2. Renewable Energy Investment Fund: an entity that installs renewable energy capacity on behalf of the owner.
3. Virtual Power Purchase Agreement: a power purchase agreement for off-site renewable energy where the owner agrees to purchase renewable energy output at a fixed price schedule.
4. Direct Ownership: an offsite renewable energy system owned by the building project owner.
5. Direct Access to Wholesale Market: an agreement between the owner and a renewable energy developer to purchase renewable energy.
6. Green Retail Tariffs: a program by the retail electricity provider to provide 100 percent renewable energy to the owner.
7. Unbundled Renewable Energy Certificates (RECs): certificates purchased by the owner representing the environmental benefits of renewable energy generation that are sold separately from the electric power.

AX104.2.2 Requirements for all procurement methods. The following requirements shall apply to all off-site renewable energy procurement methods.

1. The building owner shall sign a legally binding contract to procure qualifying off-site renewable energy.
2. The procurement contract shall have duration of not less than 15 years and shall be structured to survive a partial or full transfer of ownership of the property.
3. RECs and other environmental attributes associated with the procured off-site renewable energy shall be assigned to the building project for the duration of the contract.
4. The renewable energy generating source shall be photovoltaic systems, solar thermal power plants, geothermal power plants, and/or wind turbines.
5. The generation source shall be located where the energy can be delivered to the building site by the same utility or distribution entity; the same ISO or RTO; or within integrated ISOâ€™s (electric coordination council).
6. The off-site renewable energy producer shall maintain transparent accounting that clearly assigns production to the building. Records on power sent to or purchased by the building shall be retained by the building owner and made available for inspection by the code official upon request.

AX104.2.3 Adjusted Off-Site Renewable Energy. The process for calculating the adjusted off-site renewable energy is shown in the following equation:

\[ R_{\text{offsite}} = \sum_{i=1}^{n} P_{F_i} \cdot R_{E_i} + \sum_{i=1}^{n} P_{F_i} \cdot R_{E_i} + \cdots + \sum_{i=1}^{n} P_{F_i} \cdot R_{E_i} \]

where

\[ R_{\text{offsite}} = \text{Adjusted off-site renewable energy} \]

\[ P_{F_i} = \text{Procurement factor for the } i^{\text{th}} \text{ renewable energy procurement method or class taken from Table AX104.2.} \]

\[ R_{E_i} = \text{Annual energy production for the } i^{\text{th}} \text{ renewable energy procurement method or class} \]

\[ n = \text{The number of renewable energy procurement options or classes considered} \]

**Reason:** The new appendix deals with renewable energy and creates a path to a Zero energy design approach, similar to the zEPI that is already found in the 2015 IgCC. It is designed to build on top of the IECC which already sets the minimum energy efficiency requirement. By putting this information in an appendix, jurisdictions will have the option of adoption of these provisions in order to establish Zero as the energy target they wish to achieve.

**Cost Impact:** The code change proposal will decrease the cost of construction
The overall cost of construction and operation of buildings constructed using the Zero Annex will be lower than other comparable buildings.

Proposal # 5356

**CE264-19**
Add new definition as follows:

**ENERGY STORAGE SYSTEM (ESS).** One or more devices, assembled together, capable of storing electrical, thermal, or mechanical energy in order to supply electrical energy at a future time.

Revise as follows:

**C406.1 Requirements.** Buildings shall comply with one or more of the following:

1. More efficient HVAC performance in accordance with Section C406.2.
2. Reduced lighting power in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4.
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High-efficiency service water heating in accordance with Section C406.7.
7. Enhanced envelope performance in accordance with Section C406.8.
8. Reduced air infiltration in accordance with Section C406.9

9. On-site energy storage system installed in accordance with Section C406.10

Add new text as follows:

**C406.10 On-site energy storage system (ESS).** An on-site energy storage system with a storage capacity of at least 50 kWh that is not part of an emergency power system shall be installed. The system shall be capable of interacting with the electric grid or on-site renewable energy system or both.

**Reason:** According to the US Energy Information Administration (https://www.eia.gov/analysis/studies/electricity/batterystorage/), at the end of 2017, there were 708 MW and 867 MWh of large scale energy storage systems in operation in the United States. Several states have enacted policies that require large-scale installations of energy storage systems (over 1,000 MW) to support the growth of renewable electric generation systems on the grid and at buildings. In states with aggressive renewable portfolio standards, energy storage systems are needed to help balance the grid, especially in times of very high supply of renewable energy and low demand (e.g., “the duck curve”).

Several utilities throughout the US are providing incentives to customers for installing energy storage systems, based on a minimum capacity. Typically, the minimum capacity requirement has been on the order of 50 kWh or 50 kW for a certain number of hours of discharge.

The definition is needed for clarity to support the for new language for Energy Storage Systems in Section C406.

This is the same definition that is used in the latest version of the *International Fire Code*.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This is one of several additional efficiency options that a building owner or designer can choose from in Section C406. Based on the data from the EIA report, the range of costs for an installed energy storage system ranges from $500 to $2500 per kWh, depending on the battery size, battery chemistry, and safety code requirements. Battery prices are declining, which will reduce these costs significantly over the next several years. In addition, state and utility incentives in parts of the US significantly reduce the initial costs.
The following is the tentative order in which the proposed changes to the code will be discussed at the
public hearings. Proposed changes which impact the same subject have been grouped to permit
consideration in consecutive changes.

Proposed change numbers that are indented are those which are being heard out of numerical order.
Indentation does not necessarily indicate that one change is related to another. Proposed changes may
be grouped for purposes of discussion at the hearing at the discretion of the chair. Note that some RE
code change proposals may not be included on this list, as they are being heard by another committee.
Note also that RE1 – RE12 are moved to later in the hearing order to allow grouping consideration of
proposed changes to Chapters 1 and 3 near the beginning of the consideration of Chapters 1 and 3 of the
IECC-Commercial Provisions.

2018 International Energy Conservation Code

Revise as follows:

R102.1.1 (IRC N1101.4) Above code programs. The code official or other authority having jurisdiction shall be permitted to deem a national, state or local energy-efficiency program to exceed the energy efficiency required by this code. Buildings approved in writing by such an energy-efficiency program shall be considered to be in compliance with this code. The requirements identified as “mandatory” in Chapter 4 shall be met. Buildings with written documentation of compliance with ICC 700 at the silver level or above shall be deemed to comply with this code.

Add new text as follows:

700-15: National Green Building Standard

Reason: This adds the specific option for ICC’s above code green standard for residences, the National Green Building Standard. ICC 700 has its own “mandatory” items. Citing ICC 700 in code will mean code enforcement will not need to verify that this above code standard meets code.

Cost Impact: The code change proposal will decrease the cost of construction. This is an option and therefore will not affect cost unless it is chosen. For some this may be a less expensive option, especially if they are choosing to be in compliance with ICC 700

Analysis: The referenced standard, ICC 700-2015, is currently referenced in other 2018 I-codes.
2018 International Energy Conservation Code

R103.2 (IRC N1101.5.1) Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include the following as applicable:

1. Insulation materials and their R-values.
2. Fenestration U-factors and solar heat gain coefficients (SHGC).
3. Area-weighted U-factor and solar heat gain coefficients (SHGC) calculations.
4. Mechanical system design criteria.
5. Mechanical and service water-heating systems and equipment types, sizes and efficiencies.
6. Equipment and system controls.
7. Duct sealing, duct and pipe insulation and location.
8. Air sealing details.

R103.2.1 (IRC N1101.5.1) Building thermal envelope depiction. The building thermal envelope shall be represented on the construction documents.

Add new text as follows:

R103.2.2 (IRC N1101.5.2) Vapor management declaration. A vapor management strategy shall be documented on the construction documents. The following shall be addressed:

1. Type and class of vapor retarder used throughout the building, or listed per assembly, to manage moisture migration via diffusion as required by Section R402.1.1.
2. Vapor retarder installation scope of work to ensure proper installation.
3. Whole house ventilation strategy to be used in accordance with Section R403.6 and Section M1505.3 of the International Residential Code to ensure background ventilation moisture control.
4. Spot/local exhaust ventilation strategy to be used in accordance with Section M1505.4.4 of the International Residential Code to manage/remove moisture as it is created.
5. Flashing and weather resistant barrier type and installation details.

Reason: Currently the IRC allows one of three vapor retarder strategies to be used in a residential dwelling unit all of which require different levels of installation execution and coordination with the rest of the structure and systems that are built and the energy code features that are required by the IECC. In addition, the three strategies only address diffusion which is one of two means of moisture transport that is occurring in a dwelling unit. Moisture moves in a house by diffusion (which the vapor retarder addresses) but also with air. How we expect to control these two moisture transport mechanisms should be made prominent on the plan set to create more efficient and durable structures. This is especially true since more moisture flows into building assemblies through air transport than by the process of diffusion. This code change proposal promotes a subtle shift in our thinking to understand that moisture management is a combination of components and systems working together to protect the building from moisture related failures.

In the prescriptive section R402.1.1 Vapor retarders are required to be installed and the section refers you to the IRC and the IBC. Vapor Retarders discussed in these sections are an important part of gaining control and predictability of the moisture movement within a dwelling unit, but there is a choice that must be made as to which class of retarder will be installed. The installation of class 1 versus class 3 vapor retarder is significantly different and impacts the efficiency and durability of the structure differently.

This declaration will drive moisture management considerations into the design process resulting in assemblies that will be more moisture resistant and more efficient.

The scope of work requirement will better ensure that especially class 1 vapor retarders are installed to limit the ability of air and moisture from bypassing them and being trapped within assemblies. Is should also create a better understanding of where a class 1 vapor retarder should or should not be installed in different climate zones. For example, in climate zone 5 along the front range in Colorado we often see unsealed class 1 vapor retarders (6 mil poly) installed behind drywall on exterior walls, but no vapor retarder installed in other parts of the exterior wall assembly such as rim joint or exterior walls in bathrooms. This declaration would elevate the inconsistency of placement of vapor retarders as their installation would be more clearly thought out on the plan set than it has ever been in the past.

Whole house and spot/local ventilation are another important part of the moisture management strategy. From a whole house ventilation perspective, the code gives three choices of strategies that can be used, some of which work better in certain climate zones than others. The vapor...
management declaration, would bring the decision on systems that will be installed to the forefront for review by the plans examiner allowing for

**Cost Impact:** The code change proposal will increase the cost of construction

There would be a small cost increase associated with this proposal as the proposal merely brings existing requirements together to be reported on the plan set. I estimate that this would require no more than 1 hour of time of the designer or architect. Approximately $100 - $200.
2018 International Energy Conservation Code

Propose as follows:

R105.2.5 Final inspection. The building shall have a final inspection and shall not be occupied until approved. The final inspection shall include verification of the installation of all required building systems, equipment and controls and their proper operation and the required number efficacy of high-efficacy lamps luminaires and fixtures.

Reason: 1. Increase energy efficiency
2. Reduce inconsistency and application confusion in compliance
3. Increase code interpretation and usability
4. Resolve compliance with application, approval and inspection

Another proposal has been submitted concerning Section R404.1 Lighting equipment (Mandatory)

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Today’s cost to use the more efficient LED lamps and luminaires is now equal to or lower than the cost of CFL lamps.
RE4-19
IECC: R202 (IRC N1101.6)(New)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association (jwoestman@kellencompany.com)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

CAVITY INSULATION. Insulating material located between framing members.

Reason: The purpose of this proposal is to coordinate with the definition in IECC-C by adding a definition to IECC-R for cavity insulation to complement the existing definition for continuous insulation. Cavity insulation and continuous insulation relate to the location of insulation materials, not specific material types. Adding this definition will help clarify the code in regard to terms used to explain where insulation components are located.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposal only provides a new definition without any material change to the code or costs of compliance. There should be no cost implications.
Add new definition as follows:

**EMITTANCE.** The ratio of the radiant heat flux emitted by a specimen to that emitted by a blackbody at the same temperature and under the same conditions.

**Reason:** This definition is needed because the term emittance is used in various sections of the code and in the definition for radiant barrier and reflective insulation. It is consistent with the definition found in the 2021 IBC, ASHRAE and ASTM standards. The term emittance is used in numerous sections of this code including for: Building Envelope Requirements, Equipment Buildings, Roof Solar Reflectance and Thermal Emittance, Minimum Roof Reflectance and Emittance Options, Specifications for the Standard Reference and Proposed Designs, Roofs, and for Specifications for the Standard Reference and Proposed Designs, Walls above-grade.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Adding a definition of EMITTANCE will neither increase or decrease construction costs. This is only a definition and is identical to the definition found in the 2021 IBC and existing ASHRAE and ASTM standards.
RE6-19

IECC: R202 (IRC N1101.6)

Proponent: Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@jhatfieldandassociates.com)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Revise as follows:

FENESTRATION. Products classified as either vertical fenestration or skylights.

Skylights. Glass or other transparent or translucent glazing material installed at a slope of less than 60 degrees (1.05 rad) from horizontal, including unit skylights, tubular daylighting devices, and glazing materials in solariums, sunrooms, roofs and sloped walls.

Vertical fenestration. Windows that are fixed or operable, opaque doors, glazed doors, glazed block and combination opaque/glazed doors composed of glass or other transparent or translucent glazing materials and installed at a slope of not less than 60 degrees (1.05 rad) from horizontal.

Reason: This revision clarifies the types of products that are included in the category of "skylights" and brings the IECC Residential definition in alignment with what is in the 2018 IECC Commercial definition for "skylights" along with providing consistency with the second sentence found in the definition of "skylights and sloped glazing" in the IRC and IBC.

The intent of this change, which was accepted into the 2018 IECC Commercial, IBC and IRC definitions, was to clarify what constitutes skylights and sloped glazing, and to specifically clarify that tubular daylighting devices are to be included within that definition. This clarification is important because all fenestration, both vertical and skylights and sloped glazing, are required to be installed in such a manner as to preserve the integrity of the wall or roof.

Approval of this proposal will clarify that tubular daylighting devices are to be installed in such a manner as to preserve the weather resistant barrier of the roof in residential construction and ensure alignment with the other codebook definitions.

Bibliography: 2018 IECC, Section C202, Skylights; 2018 IBC, Section 202, [BS] Skylights and Sloped Glazing; and 2018 IRC, Section R202, [RB] Skylights and Sloped Glazing

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal will not increase the cost of construction and simply clarifies which products fall under the category of "skylights" and by default, which do not. There will not be an impact to the cost of construction.
RE7-19
IECC: R202 (IRC N1101.6), R404.1 (IRC N1104.1)

Proponent: Eric Makela, New Buildings Institute, representing New Buildings Institute (ericM@newbuildings.org)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Revise as follows:

**HIGH-EFFICACY LAMPS**. Compact fluorescent lamps, light-emitting diode (LED) lamps, T-8 or smaller diameter linear fluorescent lamps, or other lamps with an efficacy of not less than the following: 65 lumens per watt, or luminaires with an efficacy of not less than 45 lumens per watt.

1. 60 lumens per watt for lamps over 40 watts.
2. 50 lumens per watt for lamps over 15 watts to 40 watts.
3. 40 lumens per watt for lamps 15 watts or less.

R404.1 (IRC N1104.1) Lighting equipment (Mandatory). Not less than 90 percent of the permanently installed lighting fixtures shall contain only high-efficacy lamps.

Reason: The lighting section includes a requirement for a minimum percentage of "high efficiency lamps." However, the definition of "high efficacy lamps" has not been updated to reflect the changes in the market due to increased federal minimums and greater availability/affordability of LED lighting. Because of this, the code is actually becoming less stringent as the baseline for lighting equipment is raised. The proposal solves this problem by updating the definitions with lighting requirements that reflect what is actually "high-efficacy" in today's market. The proposal also simplifies the definition by reducing the number of wattage categories. The categories in the residential code are an artifact of incandescent and early compact fluorescent lamp wattages. As lamps have gotten more efficient, the higher wattage categories have become less meaningful. As lamps have gotten more efficient, the higher wattage categories have become less meaningful. Even a "100W equivalent" LED lamp and "60W equivalent" CFL lamps generally uses 15W or less, which is the lower category in the existing definition. As a result, the categories have become largely meaningless.

The proposal also accommodates high efficacy luminaires. Many luminaires on the market do not include lamps and include integrated LEDs instead. The way the current code language is written, these efficient lighting products cannot be used to meet the lighting efficiency requirements in the code. The proposal changes the term in the definition to be more inclusive, adds an efficacy requirement for integrated luminaires, and updates the code language to reflect this update.

Cost Impact: The code change proposal will increase the cost of construction. This change could potentially increase the cost of construction because it requires higher efficacy lighting (lamps and/or fixtures), which will likely eliminate some lower-end CFL options and/or push builders to newer LED technologies. However, the cost of LEDs has been steadily declining over the last several years and is expected to continue to decline. Based on an analysis by the U.S. Department of Energy's Building Energy Codes Program conducted during the 2018 IECC Code Development cycle, the estimated and projected prices for LEDs were $4.84 per lamp compared to CFLs at $3.10 per lamp. However, the rapid expansion of the LED lighting market has changed the economics. A spot check of Home Depot in early 2019 showed that a warm white, 60W equivalent A-lamp is as low as $1.24 for both CFL and LED when purchased in packs. And, LEDs are actually cheaper than CFLs at some sources. At 1000bulbs.com, on online retailer, the same lamps are $1.79/bulb for CFL and $0.99 for LED. Therefore, this code change may actually reduce the cost of construction.

Proposal # 5184
RE8-19
IECC: R202 (IRC N1101.6), R105.2.4, R403.1.1 (IRC N1103.1.1)

Proponent: Sharon Bonesteel, representing Salt River Project (sharon.bonesteel@srpnet.com); John Umphress (john.umphress@austinenergy.com)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

PROGRAMMABLE COMMUNICATING THERMOSTAT. A whole building or dwelling unit thermostat that can be monitored and controlled remotely.

SECTION R105
INSPECTIONS

Revise as follows:

R105.2.4 Mechanical rough-in inspection. Inspections at mechanical rough-in shall verify compliance as required by the code and approved plans and specifications as to installed HVAC equipment type and size, required controls, system insulation and corresponding R-value, system air leakage control, programmable communicating thermostats, dampers, whole-house ventilation, and minimum fan efficiency.

Exception: Systems serving multiple dwelling units shall be inspected in accordance with Section C105.2.4.

SECTION R403 (IRC N1103)
SYSTEMS

R403.1.1 (IRC N1103.1.1) Programmable communicating thermostat. The thermostat controlling the primary heating or cooling system of the dwelling unit shall be capable of communicating with sources external to the HVAC system and function as a basic thermostat in the absence of communicating with external sources. The thermostat shall be capable of controlling the heating and cooling system on a daily schedule to maintain different temperature set points at different times of the day. The thermostat shall include the capability to set back or temporarily operate the system and provide remote access to maintain zone temperatures of not less than 55°F (13°C) to not greater than 85°F (29°C). The thermostat shall be programmed initially by the manufacturer with a heating temperature setpoint of not greater than 70°F (21°C) and a cooling temperature setpoint of not less than 78°F (26°C).

Exception: Heating and cooling systems with proprietary internal thermostat communication functions.

Reason: This proposal adds a requirement for residential buildings to provide a communicating programmable thermostat. Communicating thermostats have become commonplace and are available from electronic stores to home improvement stores increasing brand awareness and large growth with installations in existing residential buildings. The U.S. EPA Energy Star website lists a large number of connected and smart thermostats and product manufacturers continue to add more devices and improve the depth of price points for these thermostats.

As home automation has increased in homes new products have been released that allow for occupant comfort, ease of use, convenience, security and simplicity in use. Sales of home automation products and services are projected to continue exponential growth. The use of a connected thermostat can provide energy savings for the occupants and support utilities with their demand programs if the occupant chooses to participate.

Many studies have taken place across the U.S. on these newer thermostat devices and energy savings has been seen in the study results. If actual savings are only a fraction of the study savings, the payback period is very short.

This proposal also retains some requirements from the programmable thermostat requirements in the 2018 IECC. The term and definition “programmable communicating thermostat” is taken from ICC700- National Green Building Standard (NGBS).

The exception allows use of non-connected thermostats if heating or cooling system requires a proprietary control or don't support all of the functionality of the heating or cooling system.

This proposal is modeled after Austin, Texas energy code amendment for connected thermostats.

Potential savings opportunities:
The technical energy savings potential of these individual approaches ranges from 0.3 to 1.1 quads, or 1-5% of the total primary energy consumed by U.S. homes in 2015. Put another way, saving one quad per year is equivalent to the energy consumed by about 3 million people, the electricity produced by 250 coal fired power plants or 56 million metric tons (MMT) of CO2 emissions (DOE 2012) - Fraunhofer USA Center for Sustainable Energy Systems

The Florida PDR project showed average cooling energy savings of 9.6% (498 kWh/year), but with a very high degree of variation. Median savings were 6.3% (219 kWh/year). Particularly given the very short Florida winter heating season. Average savings were 9.5% (39kWh/year) although the median was higher, at 18.5% (35 kWh/year). Space heating savings from the Nest….. average savings were 9.5% (39kWh/year) although the median was higher, at 18.5% (35 kWh/year). – Florida Solar Energy Center

6% heating savings and 14% cooling savings - 2015 AESP Conference

Average annual gas savings per home as high at 6.0% - Energy Trust of Oregon

Bibliography:

3. AESP Conference February 2015 - Cadmus Presentation – C. Aarish – “Wi-Fi Connected Thermostats” show 6% heating savings and 14% cooling savings”

Cost Impact: The code change proposal will increase the cost of construction

Cost Impact: A builder entry communicating programmable thermostat can add $50+ over the cost of a typical weekly programmable thermostat. Cost information available at many online retailers comparing weekly programmable thermostats to connected thermostats.
**2018 International Energy Conservation Code**

**SECTION R202 (IRC N1101.6)**

**GENERAL DEFINITIONS**

Revise as follows:

**ROOF RE-COVER, RECOVER.** The process of installing an additional roof covering over an existing roof covering without removing the existing roof covering.

Proposal # 5367
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Residential Code

Revise as follows:

[RB] ROOF RECOVER. The process of installing an additional roof covering over a prepared existing roof covering without removing the existing roof covering.

Reason: This simply changing the language in the definition chapter of the IECC-R (and IRC Chapter 11) to be consistent with definition in IECC-C. This is in conjunction with another proposal to change the definition in IRC Chapter 2 in the same manner so that all are uniform for better code compliance and enforcement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. As this is only aligning a definition across multiple codes, there is no change in technical requirements. Thus, there is no impact to construction costs.
Add new definition as follows:

**SAMPLING.** A process where fewer than 100 percent of a builder’s dwellings, dwelling units, or sleeping units are randomly inspected and or tested to evaluate compliance with the requirements of this code.

**Reason:** This definition is to clarify that the practice of sampling includes more than just blower door testing. The approved third party would have the opportunity to sample any requirement of the code in a development or building. This is a concept that needs to be made apparent to everyone who uses the code.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

Proposal # 5507
Add new definition as follows:

ENCLOSED REFLECTIVE AIR SPACE. An unventilated cavity with a low-emittance surface bounded on all sides by building components.

REFLECTIVE INSULATION. A material installed in an assembly consisting of one or more enclosed reflective air spaces with a surface emittance of 0.1 or less.

Revise as follows:

R303.1.1 (IRC N1101.10.1) Building thermal envelope insulation. An R-value identification mark shall be applied by the manufacturer to each piece of building thermal envelope insulation that is 12 inches (305 mm) or greater in width. Alternatively, the insulation installers shall provide a certification that indicates the type, manufacturer and R-value of insulation installed in each element of the building thermal envelope. For blown-in or sprayed fiberglass and cellulose insulation, the initial installed thickness, settled thickness, settled R-value, installed density, coverage area and number of bags installed shall be indicated on the certification. For sprayed polyurethane foam (SPF) insulation, the installed thickness of the areas covered and the R-value of the installed thickness shall be indicated on the certification. For reflective insulation, the number and thickness of the enclosed reflective air spaces and the R-value of the installed assembly shall be listed on the certification. For insulated siding, the R-value shall be on a label on the product's package and shall be indicated on the certification. The insulation installer shall sign, date and post the certification in a conspicuous location on the job site.

Exception: For roof insulation installed above the deck, the R-value shall be labeled as required by the material standards specified in Table 1508.2 of the International Building Code or Table R906.2 of the International Residential Code, as applicable.

Reason: The section at present incorporates requirements that are specific to blown or sprayed fiberglass, cellulose insulation and sprayed polyurethane foam insulation together with general requirements for thermal envelope insulation materials. However, the code is silent on reflective insulations.

The proposal adds specific requirements similar to those for the other insulation materials (as well as appropriate definitions) for a type of material, (reflective insulation) that has been on the market place for over 25 years and has had nationwide distribution and installation. These products are well established and have two associated ASTM Standards, ASTM C727, Standard Practice for Installation and Use of Reflective Insulation in Building Constructions, and ASTM C1224, Standard Specification for Reflective Insulation for Building Applications.

The U.S. Department of Energy’s website on weatherizing homes: https://www.energy.gov/energysaver/weatherize/insulation/types-insulation includes the advantages of reflective insulation systems. It states that reflective systems are most effective in preventing downward heat flow but that the effectiveness depends on spacing. This is the critical reason this code change is needed.

Many states and jurisdictional codes already include references on reflective insulation; the list follows:

IBC: 2018 – Section 720, Section 2614

Florida

- R303.1.1 Building thermal envelope insulation
- Table R303.2.1 Insulation Installation Standards
- R303.2.1.2 Substantial Contact

2017 Florida Building Code, Building, 6th Edition

Title 24, 2016, Reference Residential Appendices

- RA4.3 Envelope Measures

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal will not increase the cost of construction because only information regarding reflective insulation is being added.

Proposal # 4105

RE11-19
Add new definition as follows:

RADIANT BARRIER. A material having a low emittance surface of 0.1 or less installed in building assemblies.

Add new text as follows:

R303.1.1.2 (IRC N1101.10.1.1.2) Radiant barrier. Where installed, radiant barriers shall comply with the requirements of ASTM C1313/C1313M and shall have an emittance of 0.1 or less.

Add new standard(s) as follows:

Reason: This proposal DOES NOT require the use of radiant barriers. But rather requires that WHEN radiant barriers are used, they comply with the appropriate ASTM standard. Furthermore this proposal provides important information to the code user and code enforcement community regarding radiant barriers. Radiant barriers are typically installed in attics to reduce summer heat gains through the roof. According to the DOE's website: https://www.energy.gov/energysaver/weatherize/insulation/radiant-barriers, Radiant barriers help to reduce cooling costs by reducing radiant heat gain. To be effective, radiant barriers are very dependent of their installation because their reflective surface must face an air space.

The proposed language is being included in this section specifically because the American Society for Testing and Materials (ASTM) classifies radiant barriers as thermal insulation. The ASTM committee C16 on Thermal Insulation includes published standards for this product. Subcommittee C16.21 deals specifically with reflective products, which include reflective insulation, radiant barrier and interior radiation control coatings. C16.21 develops standards and practices for these reflective building material thermal insulating products.

The Federal Trade Commission includes radiant barrier products in “CFR Part 460 Labeling and Advertising of Home Insulation: Trade Regulation Rule”.

Radiant barrier products include a surface with an emittance of 0.1 or less that is installed in roof assemblies or attics with the low-emittance surface facing an open or ventilated air space. The low emittance material can be bonded to plastic film, woven fabric, reinforced paper, OSB or plywood. The thermal performance of radiant barriers depends on emittance and location in the attic, wall or roof assembly. Radiant barriers are predominantly installed in attic spaces below the roof deck. The low-emittance surface of radiant barrier products dramatically reduces the heat gain by radiation into the structure and attic HVAC ducts. For this reason, radiant barriers are especially effective in warm sunny climates where they provide reduced use of air conditioning. Radiant barrier products that are available include single-sheet material, multi-layer assemblies and wood sheathing with attached aluminum film or foil. The single sheet material is installed in roof assemblies by attaching directly to the roof deck, in between the rafters or trusses or to the underside of the rafters or trusses. The foil-faced sheathing is installed with the low-emittance side of the sheathing or panel facing toward the attic space to create a radiant barrier. Attic radiant barriers are in extensive use. These products have been on the market for several decades and are used by 87 of the top 100 US Builders. They have an established history and have been accepted into several regional code requirements. Over one billion square feet of the product is being installed annually.

Many state and jurisdictional codes already include references on radiant barriers. These are the state and city codes that include radiant barrier:

IBC: 2018 Section 1509 Radiant Barriers Installed Above Deck
Hawaii - Chapter 181 of Title 3, 2015, Section 407.2, Table 407.1

Texas

- The Code of the City of Austin, Texas, Supplement 1342018, Chapter 25-12, Article 12, Section R402.6

Florida

- Section 405.7.1 Installation Criteria for homes claiming the radiant barrier option
- Figure R405.7.1 Acceptable attic radiant barrier configurations
- Table R303.2.1 Insulation Installation Standards

California

- Title 24, 2016, Part 6, Subchapter 1, Definition Radiant Barrier

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal will not increase the cost of construction because it only adds informational language regarding radiant barriers.

Analysis: A review of the standard proposed for inclusion in the code, ASTM C1313/C1313M-2013, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
Revised as follows:

R303.1.3 (IRC N1101.10.3) Fenestration product rating. *U*-factors of fenestration products such as windows, doors and skylights shall be determined in accordance with NFRC 100.

**Exception:** Where required, garage door *U*-factors shall be determined in accordance with either NFRC 100 or ANSI/DASMA 105. *U*-factors shall be determined by an accredited, independent laboratory, and labeled and certified by the manufacturer.

Products lacking such a labeled *U*-factor shall be assigned the maximum *U*-factor from Section R402.5. Opaque doors lacking a default *U*-factor from Table R303.1.3(1) or label shall be assigned a default *U*-factor from Table R303.1.3 (2). The solar heat gain coefficient (SHGC) and visible transmittance (VT) of glazed fenestration products such as windows, glazed doors and skylights shall be determined in accordance with NFRC 200 by an accredited, independent laboratory, and labeled and certified by the manufacturer. Products lacking such a labeled SHGC shall be assigned the maximum SHGC from Section R402.5.

**Exception:** For existing buildings complying with Chapter 5, products lacking a labeled *U*-factor, SHGC or VT shall be assigned a default *U*-factor, SHGC or VT from Table Tables R303.1.3 (1) through (3).

**Reason:** Because of the mandatory wording of Section R402.5, you could never use the values that are in the residential default tables for new construction. This proposal makes the defaults for unlabeled fenestration that of the maximum mandatory requirements. However, in existing buildings there are times when you will not be able to determine existing *U*-factors or SHGC and the newer mandatory requirements of the new R402.5 are unrealistic, therefore the tables have been saved for those existing buildings. Opaque doors have been left with the default tables and VT was struck from the maximum requirements for new construction because A) that section doesn't cover VT and B) VT is not a residential requirement.
requirement anyway. The proposal changes the references to the tables, however the tables remain the same.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Because of the mandatory maximums set in R402.5 you could never use these default tables for new construction.

**Staff Analysis:** TABLE R303.1.3(1) [IRC N1101.10.3(1)] through R303.1.3(3) [IRC N1101.10.3(3)] remain unchanged.
RE14-19

R303.2 (IRC N1101.11)

Proponent: Eric Makela, New Buildings Institute, representing Northwest Energy Codes Group (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

R303.2 (IRC N1101.11) Installation. Materials, systems and equipment shall be installed in accordance with the manufacturer’s instructions. Grade I insulation installation requirements in RESNET/ICC 301 and the International Building Code or the International Residential Code, as applicable.

Reason: The quality of insulation installation has a significant impact on the performance of the building envelope. When insulation is not properly installed, the code does not achieve the energy savings intended by its insulation requirements. Poorly installed insulation can compromise home performance, resulting in higher energy bills for the builder’s customers and increased customer call backs due to comfort issues. Based on a report by Energy Star Certified Homes, Version 3 (Rev. 08) there is a 5% savings for heating and cooling system consumption on properly installed insulation (Grade I) vs Grade II insulation that includes more gaps, voids and compressions.

The current IECC language requires that insulation be installed to manufacturer’s instructions. This provision is difficult to enforce because installation instructions will vary based on manufacturer and type of installation (e.g. fiberglass batts versus blown fiber glass versus cellulose). Field inspectors normally don’t have ready access to manufacturer’s installation instructors when conducting an insulation inspection. Manufacturers require that their product be installed with minimal gaps, voids and compression which relates to Grade I Insulation installation but based on the U.S. DOE field study conducted in several states, less than 50% of the homes had insulation installed to Grade I insulation quality.

To address this issue, RESNET has created a new insulation installation standard that includes requirements for Grade I insulation installation for different types of insulation (e.g. fiberglass batts, blown fiber glass and cellulose). The standards language is included in latest version of RESNET/ICC Standard 301. The Grade I installation requirement will help standardize how insulation should be installed and can be used as a reference by both the insulation contractor and the building department reducing potential issues in the field over how products should be installed. This can also be used by the builder focused on quality assurance as they will know how the insulation product is require to be installed.

Grade I insulation allows very small gaps in the insulation. Voids are not allowed to extend from the interior to the exterior (i.e. the full width of a wall cavity). The product is required to be installed according to manufacturer’s specification and cut to fit around electrical junction boxes and is split around wires and pipes. Compression or incomplete fill can amount to 2% or less, if the empty spaces are less than 30% of the intended fill thickness.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

There is no cost increase in this code change as the code currently requires insulation to be installed to manufacturers installation instruction which is consistent with Grade I insulation installation requirements.

Proposal # 5193
Revised as follows:

R401.2 (IRC N1101.13) Compliance Application. Projects residential buildings shall comply with Section R401.2.1, R401.2.2, R401.2.3, or R401.2.4 one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Exception: Additions, alterations, repairs and changes of occupancy to existing buildings complying with Chapter 5.

Add new text as follows:

R407.1 (IRC N1107.1) Scope. This section establishes alternative criteria for residential buildings in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level.

Revise as follows:

R401.2.1 (IRC N1101.13.1) Prescriptive Compliance The Prescriptive Compliance Option requires compliance with Sections R401 through R404.

R401.2.2 (IRC N1101.13.2) Total Building Performance The Total Building Performance Option requires compliance with Section R405, and the provisions of Sections R401 through R404 indicated as “Mandatory.”

R401.2.3 (IRC N1101.13.3) Energy Rating Index. The Energy Rating Index (ERI) Option requires compliance with Section R406.

R401.2.4 (IRC N1101.13.4) Tropical zones The Tropical Climate Zone alternative requires compliance with Section 407.

SECTION R407 (IRC N1107) TROPICAL CLIMATE ZONE

R407.1 (IRC N1107.1) Scope. This section establishes alternative criteria for residential buildings in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level.

Revise as follows:

R401.2.1 (IRC N1101.13.1) R407.2 (IRC N1107.2) Tropical zone. Residential buildings in the tropical zone at elevations less than 2,400 feet (731.5 m) above sea level shall be deemed to be in compliance with this chapter provided that the following conditions are met: compliance with this sections requires the following:

1. Not more than one-half of the occupied space is air conditioned.
2. The occupied space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in conditioned spaces has a solar heat gain coefficient of less than or equal to 0.40, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section R404.
6. The exterior roof surface complies with one of the options in Table C402.3 or the roof or ceiling has insulation with an R-value of R-15 or greater. Where attics are present, attics above the insulation are vented and attics below the insulation are unvented.
7. Roof surfaces have a slope of not less than one-fourth unit vertical in 12 units horizontal (21-percent slope). The finished roof does not have water accumulation areas.
8. Operable fenestration provides a ventilation area of not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

Reason:
This proposal intends no technical changes. It will make the code clearer and easier to use, particularly if companion proposals to identify ‘mandatory’ provisions in tabular formats are approved.
This proposal reorganizes the general requirements of Chapter 4 of the IECC-R to:

- Retitle R401.2 as “Application” to be consistent with the title of the parallel section in the IECC-C;
- More clearly identify the optional compliance paths available to the designer by providing titles;
- Retitle the R405 “Simulated Performance Alternative” performance option as “Total Building Performance” to be consistent with the title of the parallel section in the IECC-C;
- Relocate the specific technical requirements of the tropical zone alternative from the general section of the code to a standalone section; while providing a reference in the general section to the new tropical zone section;
- Provide a needed reference to the requirements for existing buildings in Chapter 5.

Consistent nomenclature would support training and education, ease of use and code administration.

A separate proposal has been made to relocate all of the ‘mandatory’ requirements of the performance option currently listed in Sec. R401.2(2) to a new table in Sec. R405. This is consistent with approach currently used in R406.2, (mandatory requirements for the ERI alternative) whereby all mandatory requirements are referenced from the section to which they apply. (Note that another separate proposal would move the ‘mandatory’ sections referenced in R406.2 to a new table within R406 to maintain consistency of approach between R405 and R406).

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal restructures and simplifies existing information and simplicity, it does not create or eliminate requirements.
2018 International Energy Conservation Code

Revise as follows:

R401.2 (IRC N1101.13) Compliance. Projects shall comply with all provisions of Chapter 3 as applicable; the provisions of Chapter 4 labeled “Mandatory;” and one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Reason: The purpose of this code change proposal is to simplify and clarify the applicability of the IECC’s mandatory provisions across all compliance paths. The proposal will also clarify the applicability of Chapter 3 to all compliance paths, including the Energy Rating Index option of Section R406, something that may not be obvious to a code user who may be more familiar with other rating systems. This code change will not change any requirements of the code, but it will bring essential clarification to the applicability of certain measures to all compliance paths. This will improve compliance and enforcement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal does not change any requirements, but merely clarifies the application of the code.
2018 International Energy Conservation Code

Revise as follows:

R401.2 (IRC N1101.13) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.
4. The simplified equivalent compliance alternative approach in Section R407.

Add new text as follows:

R407 (IRC N1107)

SIMPLIFIED EQUIVALENT COMPLIANCE ALTERNATIVE

R407.1 (IRC N1107.1) Scope. This section establishes criteria for compliance using heating and cooling load analysis.

R407.2 (IRC N1107.2) Requirements. Compliance with this section requires that the provisions identified in Sections R102.3, R403.5, R403.8, R403.9, R403.10, R403.11, and R404.1 be met.

R407.3 (IRC N1107.3) Equivalent HVAC building load. The ratio of the space cooling load and space heating load to conditioned floor area shall be less than or equal to the values in Table R407.3.

<table>

</tbody>
</table>

R407.4 (IRC N1107.4) TESTING

R407.4.1 (IRC N1107.4.1) Air leakage. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding the design infiltration rate in the load calculations. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E779 or ASTM E1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other
infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

R407.4.1 (IRC N1107.4.1) Duct leakage. Ducts shall be tested in accordance with R403.3.3 and R403.3.4.

Reason: This is a refinement of previous code change proposal RE180-16. The committee recommended disapproval for the following reason: “This is a good concept that would be easy to use but the numbers need some refinement.”

This proposal responds to the committee’s comment on RE180-16 by providing specific compliance numbers for each climate zone. Weather data from representative cities of each climate zone as suggested by Pacific Northwest National Laboratory (PNNL) was entered in Wrightsoft Manual J software. Thermal envelope values (insulation, fenestration, air leakage) from the prescriptive 2018 IECC path for each climate zone was entered using the PNNL standard house design. This is consistent with PNNL protocol.

R407.2 includes requirements not addressed by heating and cooling load including service hot water, exterior energy use, and lighting. R102.3 is included to highlight the need for supporting mechanical system design documentation.

R407.4 requires testing to demonstrate the building is built as designed. A blower door test may not exceed the design infiltration rate in the load calculations. Ducts have the same testing requirements as the prescriptive path in R403.3.3 and R403.3.4.

The Simplified Equivalent Compliance Alternative provides the designer, engineer and builder team with another path to comply with climate zone equivalent energy performance targets. The peak heating and cooling loads are already calculated by the design team and drives the HVAC equipment size decision. This option rewards design work value that already exists.

This method is intended as an alternate method for complex residential buildings and HVAC system designs. Energy code compliance documentation at permit application will be greatly reduced as the compliance metric does not require volumes of paperwork.

This compliance path will shorten plan review time and reduce costs in both the public and private sectors.

The targets are fuel neutral.

Note 1 - the climate zones are based on this table:

<table>
<thead>
<tr>
<th>TABLE R301.3(2) INTERNATIONAL CLIMATE ZONE DEFINITIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ZONE NUMBER</strong></td>
</tr>
<tr>
<td><strong>IP Units</strong></td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3A and 3B</td>
</tr>
<tr>
<td>4A and 4B</td>
</tr>
<tr>
<td>3C</td>
</tr>
<tr>
<td>4C</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>

For SI: °C = \( [(°F) - 32] / 1.8 \).

Note 2 – We provided numbers for Climate Zone 0 using weather data from a CZ0 city (Dubai) but used thermal envelope R and U values and air leakage for CZ1 under the 2018 IECC.

WHAT TO LOOK FOR ON THE COMPLIANCE DOCUMENTS:
Following are example load calculations for climate zone 6 in Helena, MT. The heating load highlighted in the report is 27,725 Btuh; divided by the 2,400sqft conditioned floor area of this house gives a Btuh/sqft of 11.55. This is less than the value in table R407.3 and therefore complies. A similar calculation can be done for the cooling load. This house will need to pass a blower door test of 1080cfm at 50 Pa per the highlighted infiltration value in the report.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is an option that gives considerable freedom to the design team. Options and flexibility may lower construction cost.
2018 International Energy Conservation Code

Revise as follows:

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall indicate the predominant $R$-values of insulation installed in or on ceilings, roofs, walls, foundation components such as slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces; $U$-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing performed on the building. Where there is more than one value for each component, the certificate shall indicate the value covering the largest area. The certificate shall indicate the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters. Where onsite renewable systems have been installed, the array capacity kilowatt size, inverter efficacy, panel tilt and orientation shall be noted on the certificate.

Reason: Four reasons why this proposal should be supported:

1. The Code requires that the efficiency rating of every energy-related building component of the home be observable or documented. Insulation $R$-values, furnace AFUE and water heater EF ratings, Window $U$-value and SHGC, as well as blower door and duct leakage testing results to name a few. Onsite renewables systems are the one exception which this proposal is striving to address.

2. The homebuyer must have access to knowledge of the energy comments of their home. The label required in Section R401.3 provides it with the notable exception of onsite renewables.

3. Green appraisal addendums and energy efficient mortgages are becoming more common in the market and the ability to easily gather the energy component information from a home is especially needed after the first sale. The certificate is to be a permanent feature of the home to allow the value of the efficiency features of the home to be recognized and assessed as an impact on the cost of ownership.

4. Lastly, third-party Inspection agencies, especially those working within section R405 and R406, need this information in order to develop compliance and marketing documents. The inclusion of onsite renewables on this certificate will change the renewable industry by ensuring that the information is passed on to all owners in a timely manner that does not impact receiving the certificate of occupancy or the closing of the home.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal would not impact the cost of construction. It does not require the inclusion of onsite renewables only the reporting of it when it is installed.
2018 International Energy Conservation Code

Revise as follows:

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent building certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label, or other required labels. The certificate shall indicate the predominant R-values:

1. The date the certificate is installed;
2. The dwelling address;
3. The predominant installed R-values, their location, and type of insulation installed in or on ceilings, roofs, walls, rim/band joist, foundation components such as slabs, basement walls, crawl space walls and floors and;
4. Ducts outside conditioned spaces;
5. U-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration;
6. The types, and efficiencies, input ratings, manufacturers, and model numbers and efficiencies of heating, cooling, and service water heating equipment.
7. The structure's calculated heat loss, calculated cooling load, and calculated heat gain.
8. The building's designated continuous and total ventilation rates.
9. The certificate shall list the mechanical ventilation system type, location, and capacity
10. The building's designated continuous and total ventilation rates.
11. The building's designated continuous and total ventilation rates.
12. The building's designated continuous and total ventilation rates.

The certificate shall indicate the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace,” or “baseboard electric heater,” as appropriate.

An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters.

Reason: The language in section R401.3 is revised by replacing the word “permanent” in the first sentence with the word “building.” This change is necessary because the term “permanent certificate” is not used in the industry while the term “building certificate” is, and building certificate is the correct term to be used, in that pertains to the document being referenced in this section. The term “permanent” ambiguity in that one person's definition of permanent is very different than another person's definition of permanent. Using the term building certificate will add to consistency of the code because we do define the term “Building” in the code.

Additional required items are added to the IECC list of certificate requirements: the date the certificate is posted so that the building is complete and all the information needed can be added to the certificate; the contractor name and license number or the homeowner name and contact information (if acting as the general contractor); the insulation product and R-values in the Rim/Band joist area where the Rim/Band joist area is typically insulated with a different system or product than the rest of the home; information on the buildings mechanical ventilation system because this system is an important component of the building's air quality and durability as required by other provisions of the code; and input rating, model numbers, and equipment efficiencies of all the heating and cooling equipment.

These requirements provide consistency with regard to building certificate requirements and a builder can now use the Certificate as a checklist for information that is required at permit application time. Without this information it is virtually impossible to do a complete and proper plan review and know how the building is being built. (See Example )

Cost Impact: The code change proposal will decrease the cost of construction. These items are already being calculated and done as part of the building's construction. All this change is doing is asking for the information at the time of permit application. It is important to design the building and then build it instead of building it and then trying to make it work with the design. Providing this information up front assures that the building is designed properly and it the specs it will need to be built and inspected to.
RE20-19
IECC: R401.3 (IRC N1101.14)

Proponent: Jason Vandeveer, representing Self (jvandeveer@eepartnership.org)

2018 International Energy Conservation Code
Revise as follows:

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall indicate the predominant $R$-values of insulation installed in or on ceilings, roofs, walls, foundation components such as slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces; $U$-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing performed on the building. Where there is more than one value for each component, the certificate shall indicate the value covering the largest area. The certificate shall indicate the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters. The certificate shall indicate the name of the builder who applied for the building permit, the code edition under which the structure was permitted and the compliance path used.

Reason: This is potentially valuable information to the homeowner or future contractor working on the home

Bibliography: N/A

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Adding a few items to a certification sheet doesn't cost anything. It is only documentation.
Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Harry Misuriello, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org)

2018 International Energy Conservation Code

Revise as follows:

R401.3 (IRC N1101.14) Certificate (Mandatory). A permanent certificate shall be completed by the builder or other approved party and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall indicate the predominant R-values of insulation installed in or on ceilings, roofs, walls, foundation components such as slabs, basement walls, crawl space walls and floors and ducts outside conditioned spaces; U-factors of fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing performed on the building. Where there is more than one value for each any component of the building envelope, the certificate shall indicate both the value covering the largest area and the area-weighted average value if available. The certificate shall indicate the types, sizes and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace or baseboard electric heater is installed in the residence, the certificate shall indicate “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be indicated for gas-fired unvented room heaters, electric furnaces and electric baseboard heaters. For buildings where an Energy Rating Index score is determined in accordance with Section R406, the Energy Rating Index score, both with and without any on-site generation, shall be listed on the certificate.

Reason: The purpose of this code change proposal is to make minor but important updates to the certificate that will reflect changes made to the IECC in recent code cycles and include other information that will be beneficial for compliance purposes and for future homeowners. Most importantly, for homes with an Energy Rating Index score, the certificate will be required to provide the actual ERI score achieved with and without on-site generation (since the compliance requirements are different under each option). This proposal would also require the certificate to provide additional detail on thermal envelope efficiency (where available) and HVAC equipment size. This information should all be readily available at construction, and it will take very little effort to transfer it onto the permanent certificate. However, this information may be difficult or impossible to recreate down the road and will be useful for maintenance and future replacement. These are all reasonable improvements to the certificate that will benefit all future owners of the home.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The information required by this proposal will already be available at construction. The only change is to require the information to be recorded on the permanent certificate. Over the useful life of the home, we expect that putting this information in one place could save a homeowner significant money and effort.
RE22-19

IECC: R402.1 (IRC N1102.1)

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Gutman, BCAP-IBTS, representing BCAP-IBTS (mgutman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

R402.1 (IRC N1102.1) General (Prescriptive). The building thermal envelope shall comply with the requirements of Sections R402.1.1 through R402.1.5.

Exceptions:

1. The following low-energy buildings, or portions thereof, separated from the remainder of the building by building thermal envelope assemblies complying with this section shall be exempt from the building thermal envelope provisions of Section R402.
   1.1. Those with a peak design rate of energy usage less than 3.4 Btu/h · ft² (10.7 W/m²) or 1.0 watt/ft² of floor area for space-conditioning purposes.
   1.2. Those that do not contain conditioned space.

2. Log homes. The prescriptive R-value requirement in Table R402.1.2 shall not apply to the opaque walls of log homes where the walls are constructed from logs at least 7 inches in diameter and the homes are designed in accordance with ICC 400.

Reason: The purpose of this code change proposal is to clarify, narrow and place reasonable limits on the log homes exception that was added to the 2018 IECC, which will help improve compliance and enforcement, save energy, and improve comfort. Specifically, the proposal will limit the exception to opaque wall R-values, where there are 7-inch or greater diameter logs, rather than permit an exception to all thermal envelope requirements for any log home.

Prior to the 2018 IECC, log homes were required to comply with the same requirements as all other homes. The current overly broad exception was added in 2018, which reduced the energy efficiency requirements for certain log homes and shifted part of compliance from the IECC to ICC 400. The exception, as currently contained in Section R402.1, may be seen as somewhat ambiguous as to which components of the log home are exempt from the IECC requirements. A strict reading of the actual language of Section R402.1 (which we believe is the correct reading) would only substitute the prescriptive component R-values and U-factors in ICC-400 for the values contained in Sections R402.1.1 through R402.1.5. The remaining requirements in the IECC – including air leakage testing, duct tightness and testing, equipment sizing, etc. -- would still apply. However, some have suggested that the current code language completely exempt log homes from all IECC thermal envelope requirements in favor of ICC-400 – a huge expansion of the exception that would permit these homes to waste substantially more energy than a home built to the IECC. Our proposal would resolve this issue.

In addition, although we can appreciate the difficulty of achieving code-compliant prescriptive wall R-values in solid log structures, we believe it is unnecessary to exempt these homes from all thermal envelope or any other efficiency requirements -- particularly those unrelated to the log walls.

By limiting the exception to the opaque walls, this proposal will retain reasonable IECC efficiency requirements for all other parts of the log home as they existed prior to establishing the exception.

This proposal uses 7-inch diameter logs as the cutoff for the exception to help ensure at least some minimum degree of efficiency in the walls. The R-value for wood ranges between 1.41 per inch for most softwoods and 0.71 for most hardwoods. See https://www.energy.gov/energysaver/types-homes/energy-efficiency-log-homes At a 7-inch diameter, the best possible U-factor for a log wall aligns with an R-13 wall (0.084). Depending on the type of wood, the insulating value of the 7-inch log wall could be much less. While these R-values are equal to or substantially less than even the least stringent wood frame wall R-values for climate zones 1 and 2 (R-13), we recognize that there is some additional benefit from log walls with regard to thermal mass. Only log walls thick enough to maintain a reasonable level of efficiency, however, should qualify for the exemption. We believe that the 7-inch proposed minimum diameter is a reasonable compromise.

It should be kept in mind that for log homes that do not fall within this exception, the IECC offers a range of additional compliance options, including the Total UA, performance path, or ERI option to provide ample trade-off flexibility without sacrificing any energy efficiency.

Cost Impact: The code change proposal will increase the cost of construction

For those log homes that would utilize the exception but may no longer qualify, additional costs may be incurred to bring the home into compliance, although the cost would be no greater than before the exception was established in 2018. However, the proposal will reduce operating costs and improve comfort for actual log homeowners and other occupants who will benefit from lower energy costs over the 70 to 100 year expected useful lifetime of a well-built log home.
2018 International Energy Conservation Code

Revised as follows:

**Reason:** This proposal does not change the stringency of requirements for basement and crawlspace walls. It does improve clarity and moves an alternative compliance option (13+5ci) from the footnote to the table. The clarification is made by adding a ‘ci’ designator for the continuous insulation components in the table. This is also carried through in the footnote ‘c’. Footnote ‘c’ is further clarified by consistently referring to “wall” rather than in some cases basement and in other cases “home” with no mention of “crawlspace”. The footnote applies to basement and crawlspace walls as noted in the heading of the table columns. Also, the word “surface” is added to clarify that where continuous insulation is used it should be applied to the surface of the foundation wall (and any additional cavity insulation applied to the interior side of the continuous insulation). This is necessary to avoid poor practice that can lead to moisture problems. Where foam sheathing is placed directly on the foundation wall it can help prevent moisture problems.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal is a non-technical clarification that does not change stringency of requirements.
RE24-19

IECC: TABLE R402.1.2 (IRC N1102.1.2), TABLE R402.1.4 (IRC N1102.1.4)

Proponent: Lauren Urbanek, representing Natural Resources Defense Council (lurbanek@nrdc.org)

2018 International Energy Conservation Code

Revise as follows:

TABLE R402.1.2 (IRC N1102.1.2)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

Portions of table not shown remain unchanged.

</tr>
</tbody>
</table>

a. Nonfenestration $U$-factors shall be obtained from measurement, calculation or an approved source.

Reason: This proposed change to the fenestration $U$-factor aligns the IECC with the ENERGY STAR Version 6.0 specification. The ENERGY STAR specification for windows in climate zones 1-4 has been in place since January 1, 2015. The ENERGY STAR specification for windows in climate zones 5-8 has been in place since January 1, 2016. Products that meet the ENERGY STAR standard are widely available and have been for some time. In 2016 – the first year the ENERGY STAR Version 6.0 specification was in effect for all climate zones – ENERGY STAR windows already had an 83% market share. Replacing old windows with ENERGY STAR certified windows lowers household energy bills by an average of 12 percent nationwide. The Environmental Protection Agency performed a cost-effectiveness analysis of Version 6.0 and found it to be cost-effective. That analysis can be found here: http://www.energystar.gov/sites/default/files/ESWDS-ReviewOfCost_EffectivenessAnalysis.pdf

EPA notes that manufacturers can meet the proposed specification for climate zones 5-8 using either double- or triple-pane windows. In general, EPA's data show that double-pane windows that meet the northern climate zone specification are cost effective for consumers. Feedback that EPA
has received from stakeholders confirms that new glass technologies, improvements in frame performance, and/or better spacer performance can help many product lines meet the proposed Northern Zone criteria with double-pane windows.

Cost Impact: The code change proposal will increase the cost of construction
The code change proposal may increase the cost of construction. Given the level of market penetration of ENERGY STAR products, by the time the 2021 code is adopted many builders will already be meeting the improved requirements. In some limited cases, builders may incur increased costs. EPA estimates that there is a cost of $20 per window to go from the 2009 code requirements to ENERGY STAR Version 6.0. However, the U-factor requirements in the 2018 code are already significantly more stringent than the 2009 code requirements, so we would expect the marginal cost per window to be less.

NR = Not Required. For SI: 1 foot = 304.8 mm.

- **a.** R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
- **b.** The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

**Exception-Exceptions:**

1. In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.
2. In Climate Zones 1 through 8, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that one of the primary functions is solar thermal collection.

- **c.** "10\(1/3\)" means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. "15\(1/1\)" means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. Alternatively, compliance with "15\(1/1\)" shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
- **d.** R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.
- **e.** There are no SHGC requirements in the Marine Zone.
- **f.** Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
Reason: Exception: In Climate Zones 1 through 8, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that one of the primary functions is solar thermal collection.

1. Skylight/solar thermal collector combination units have two primary functions, collect thermal energy, and provide light. The amount of thermal energy collection and light transmittance is directly related to the amount of solar irradiance incident on the unit. As the solar irradiance incident on the unit increases, both the thermal energy collection and light transmittance increases. The thermal energy that is collected is transferred to an HTF (heat transfer fluid) and diverted away from the unit into a storage tank. During this process, \( G_{IPS} \), the incident solar radiation on the inside pane of the skylight is a function of the \( G_{TISR} \), total incident solar radiation and the \( G_{SRT} \), solar radiation transmitted \( (G_{IPS} = G_{TISR} \cdot G_{SRT}) \). Unlike a normal skylight, skylight/solar thermal collector combination units have the ability to divert the total incident solar radiation away from the skylight and into an HTF where it can be stored and utilized for domestic hot water needs.

2. Currently, there is no test standard for skylight/solar thermal collector combination units to measure how the SHGC of the unit changes over time as a result of the collect.
**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is merely an exemption and will not pose any construction cost implications.
R402.1.4 (IRC N1102.1.4) U-factor alternative, or F-factor alternative. An assembly with a U-factor or F-factor equal to or less than that specified in Table R402.1.4 shall be an alternative to the R-value in Table R402.1.2.

a. Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.
b. Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall U-factors shall not exceed 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.
c. In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall U-factor shall not exceed 0.360.
d. F-factors for heated slabs correspond to the configuration described by footnote (d) of Table R402.1.2.

R402.1.5 (IRC N1102.1.5) Total UA Component performance alternative. Where the proposed total building thermal envelope UA, the sum of U-factor times assembly area, thermal conductance, is less than or equal to the total UA resulting from multiplying the U-factors required total building thermal envelope thermal conductance using factors in Table R402.1.4 by the same assembly area as in the proposed building, the building shall be considered to be in compliance with Table R402.1.2. The UA calculation shall be performed total thermal conductance shall be determined in accordance with Equation 4-1. Proposed U-factors and slab-on-grade F-factors shall be determined using a method consistent with the ASHRAE Handbook of Fundamentals and shall include the thermal bridging effects of framing materials. In addition to total thermal conductance compliance, the SHGC requirements shall be met.

\[(U_pA + F_pP) < (U_pA + F_pP)\] (Equation 4-1)

where:

\[U_pA\] = the sum of proposed U-factors times the assembly areas in the proposed building
F_P = the sum of proposed F-factors times the slab-on-grade perimeter lengths in the proposed building

U_A = the sum of U-factors in Table R402.1.4 times the same assembly areas as in the proposed building

F_P = the sum of F-factors in Table R402.1.4 times the slab-on-grade perimeter lengths as in the proposed building

R402.2.10 (IRC N1102.2.10) Slab-on-grade floors. Slab-on-grade floors in contact with the ground with a floor surface less than 12 inches (305 mm) above or below grade shall be insulated in accordance with Table R402.1.2. The insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall. Insulation located below grade shall be extended the distance provided in Table R402.1.2 by any combination of vertical insulation, insulation extending under the slab or insulation extending out from the building. Insulation extending away from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall. Slab-edge insulation is not required in jurisdictions designated by the code official as having a very heavy termite infestation.

Reason: to clarify how slab-on-grade UA calculations are to be done and provide an approved source for F-factor data. Although standard calculation procedures (such as ASHRAE’s) cover the incorporation of slab conductances, and existing tools (such as REScheck) support slab perimeter insulation tradeoffs in the UA alternative, the code currently gives little direction on slab-on-grade component performance calculations. This clarifies the slab calculation.

This is clarification only; there is no direct impact on energy use.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost impact since there is no change in requirements. This just clarifies how insulation for slab on grade can be treated in the UA tradeoff calculation.

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

**Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

c. “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. Alternatively, compliance with “15/19” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.

d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.
Reason: This proposal does not change the stringency of insulation requirements for wood frame walls. The intent of this proposal is to: (1) include an additional equivalent insulation option for cavity insulation (currently an equivalent cavity insulation only option is missing in Climate Zones 6-8) and (2) provide for equivalent continuous insulation only options which are also currently missing. With the addition of these options, the table provides a simple yet complete set of insulation options for location of insulation on wood frame wall assemblies for each climate zone. This is intended to improve the usefulness of prescriptive options and show the full range of equivalent insulation options (e.g., cavity only, hybrid cavity + continuous, and continuous only). It is also intended to address concerns that the prescriptive table favors certain options over others by excluding viable options in some climate zones. This approach also provides more flexibility to coordinate insulation options with vapor retarder provisions in the building code which vary by climate as well as insulation strategy. With this flexibility, users can more readily choose between insulation options that provide equivalent assembly U-factor (as a minimum requirement of the energy code) yet have different capabilities and functions with respect to comfort, air-tightness, moisture control, thermal bridging mitigation, and other factors that are important to an overall code-compliant wall assembly. The thermal equivalency of the proposed options is demonstrated in the assembly U-factor analysis tables that follow.

| Total Wall R-Values                   | 20.12              |

**NOTE:** R-0 + R13.2ci is rounded to R-0 + R15ci to align with current convention for continuous insulation R-values in Table R402.1.1.

### R30 option (cavity only):

Climate Zone 6, 7 and 8 U-Factor Calculation Spreadsheet
NOTE: As shown in the calculation above, the R-30 cavity insulation only wall is dependent on thickness of framing (2x8) to satisfy the required maximum U-factor of 0.045. This is because the R-value of the studs (framing path) has an important effect on the overall effective R-value or U-factor of the assemblies with cavity insulation only. Where a 2x6 wall is used, R-38 insulation would be required because a 2x6 stud has a lower R-value than a 2x8 stud and, consequently, more cavity insulation R-value is needed to make up the difference (even though the cavity depth of a 2x6 wall is smaller). This is demonstrated in the table below. While R-38 insulation in a 2x6 wall cavity is possible, it can only be done with a limited selection of cavity insulation material with a 6.9 R/in or greater (i.e., closed cell spray foam). For this reason the proposal uses the R-30 (2x8) option which is more inclusive of various cavity insulation materials having an R-4.1/in or greater. Other options include combinations of cavity insulation materials that add up to R30 (e.g., flash and batt) or double-stud walls that can comply through the U-factor approach.

</tr>
</tbody>
</table>

NOTE: R-0 + R18.7ci is rounded to R-0 + R20ci to align with current convention for continuous insulation R-values in Table R402.1.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The proposal merely provides additional equivalent options for compliance to ensure no one approach or insulation material or its location on or in an assembly is preferentially treated over another in any of the climate zones.

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

c. "10k or 13k" means R-10 R-5 continuous insulation (CI) on the interior or exterior of the home wall or R-13 cavity insulation on the interior of the basement wall. "15k or 19k" means R-15 continuous insulation (CI) on the interior or exterior surface of the home wall or R-15 cavity insulation on the interior of the basement wall. Alternatively, compliance with "10k or 13k" "15k or 19k" shall be R-13 cavity insulation on the interior of the basement wall plus in addition to R-5 continuous insulation on the interior or exterior of the home wall.

d. R-5 continuous insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zones.
Reason: This proposal is a clarification of insulation requirements in relation to cavity and continuous insulation applications. This proposal is intended to clarify compliance with Section R402.1.3. In Table R402.1.2, “ci” is inserted wherever continuous insulation is a prescriptive requirement and / or option. Also, the “+” in several cells is replaced with “&” to more appropriately indicate the continuous insulation (ci), along with the cavity insulation, are both required where the CZ requires both. In footnote “c” replacing “and” with “in addition to” to clearly communicate in these situations both cavity insulation and continuous insulation are required.

In the basement and crawl space wall columns, the “/” is replace with “or” to clearly communicate either is acceptable (ci or cavity insulation).

Also, suggesting a bit of cleanup in footnote “c”. Footnote “c” is used for Basement Wall R-value and for Crawl Space Wall R-value. Use of “basement” in the footnote is not quite accurate since this footnote applies equally to basement or crawlspace walls. And, use of “home” is too broad. It seems the use of “wall” is better than the current text. And, in footnote “c” replacing “and” with “in addition to” to clearly communicate in these situations both cavity insulation and continuous insulation are required.

In the crawl space wall column, inserting footnote “f” similar to where footnote “f” is placed in the basement wall column, and modifying footnote “f” to include crawl space walls. It seems logical that crawl space wall insulation would be required – or not required – per the same criteria as basement walls.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There should be no cost implications as no technical changes are intended.

However, if adding footnote “f” to the crawl space wall column is a technical change, this proposal would decrease the cost of construction.

<td>0.098</td>
<td>0.047</td>
<td>0.091</td>
</tr>
</tbody>
</table>

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums, U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the labeled R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

c. *10/13* means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. *15/19* means R-15 continuous insulation on the interior or exterior of the home or R-18 cavity insulation on the interior of the basement wall. Alternatively, compliance with *15/19* shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.

d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.

h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, *13+5* means R-13 cavity insulation plus R-5 continuous insulation.

i. Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

Cost Impact: The code change proposal will increase the cost of construction

Requiring more insulation will increase the cost of construction, but the resulting energy and cost savings will recoup the initial costs and will continue to benefit consumers over the useful life of the home.

Reason: The purpose of this code change proposal is to upgrade and strengthen the requirements for wall insulation in climate zones 4 and 5 by making the requirements equal to the current requirements in climate zone 6. This will make homes more comfortable for occupants and reduce energy costs over the life of the building.

Because wall insulation is most cost-effectively installed during construction, walls should be insulated to the maximum cost-effective levels at that time, rather than expecting homeowners to upgrade them at some later date. This approach is consistent with the intent of the IECC (R101.3) to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

The proposed improvements represent the next step in commonly-available products and construction practices. Using DOE’s cost-effectiveness methodology, we found these R-values to offer substantial net life cycle savings and be clearly cost-effective for the homeowner/consumer in both climate zones.

Proposal # 3994

RE29-19
RE30-19
IECC: TABLE R402.1.2 (IRC N1102.1.2)

Proponent: Ben Edwards, representing Mathis Consulting Co. (ben@mathisconsulting.com)

2018 International Energy Conservation Code
Revise as follows:

TABLE R402.1.2 (IRC N1102.1.2)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>CLIMATEZONE</th>
<th>GLAZED FENESTRATION SHGC&lt;sup&gt;a&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 exceptMarine</td>
<td>0.40 0.35</td>
</tr>
</tbody>
</table>

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

   Exception: In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

c. “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation on the interior of the basement wall. Alternatively, compliance with “15/19” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.

d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.

h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, “13+5” means R-13 cavity insulation plus R-5 continuous insulation.

i. Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

Reason: In 2017 the US Environmental Protection Agency (EPA) reevaluated their methodology for determining what fenestration products are available to consumers in a Window Technology Pathways white paper (see bibliography). Components from the National Fenestration Rating Council Certified Product Directory were categorized, and prevalence of performance technologies were reported. Of concern for this proposal, SHGC performance was placed into 4 bins:

“To understand the distribution of SHGC at different U-factors, EPA grouped products into four SHGC bins that correspond to the Version 6.0 ENERGY STAR criteria: High SHGC (>0.40), Medium SHGC (0.26 – 0.40), Low SHGC (0.20 – 0.25), and Very Low SHGC (<0.20). The SHGC bins provide another dimension to analyze the performance of different pathways.” -EPA pg.6 (PDF pg.8, emphasis added)

In the Windows Pathway Analysis Workbook the summarized data show that for a U-factor range of 0.28 - 0.32 (i.e., the typical market windows used to comply with the IECC-2018 climate zone 4 requirement of U=0.32) about 56% of the products are less than SHGC=0.25, 92% are less than SHGC=0.40, and only 8% would be considered “High SHGC” (SHGC > 0.40). Again, these are all of the window options in NFRC’s CPD, including niche/specialized function windows, which never would be used for prescriptive compliance. Further, the DOE-Field-Study-SHGC-snapshot.JPG (from the DOE Field Study, an investigation into actual construction practices, see bibliography), surveyed states and found that windows, almost exclusively, were under the SHGC=0.35 proposed value. It is important to note that all states surveyed (other than NC, using the NCECC2012; and MD, using the IECC2012) had no SHGC requirement in climate zone 4.

The Workbook is found at:
https://www.energystar.gov/sites/default/files/asset/document/Window%20Technology%20Pathways%20Analysis%202.15.17.xlsx

At
https://www.energystar.gov/products/building_products/residential_windows_doors_and_skylights/partners
The relevant information is on the “Summary Tables” tab.

To be clear: Even in jurisdictions with no SHGC requirement, almost no windows performed worse than this proposed value, which is the almost exclusive majority of readily available windows. The prescriptive compliance path in the new, 2021 IECC should, at least, represent the standard practice of installed window performance, with an SHGC requirement at 0.35. Because meeting this minimal requirement already is standard practice, this proposal should not be considered to increase the cost of construction.

Bibliography:

Cost Impact: The code change proposal will increase the cost of construction
The selection of “increase the cost of construction” is a technicality. Please see reason statement.

**NR** = Not Required. For St. 1 foot = 304.8 mm.

- **a.** R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
- **b.** The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.
- **Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.
- **c.** “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-18 cavity insulation at the interior of the basement wall. Alternatively, compliance with “15/19” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
- **d.** R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.
- **e.** There are no SHGC requirements in the Marine Zone.
- **f.** Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
- **g.** Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.
- **h.** The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, “13+5” means R-13 cavity insulation plus R-5 continuous insulation.
R402.2.1 (IRC N1102.1.1) Ceilings with attic spaces. Where Section R402.1.2 requires R-38 insulation in the ceiling, installing R-30 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-49 insulation in the ceiling, installing R-38 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-49 insulation wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-60 insulation in the ceiling, installing R-49 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-60 insulation wherever the full height of uncompressed R-49 insulation extends over the top plate at the eaves.

This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

R402.2.2 (IRC N1102.2.2) Ceilings without attic spaces. Where Section R402.1.2 requires insulation R-values greater than R-30 but less than or equal to R-49 in the ceiling and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the minimum required insulation R-value for such roof/ceiling assemblies shall be R-30. Where Section R402.1.2 requires insulation greater than R-49 in the ceiling and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the required insulation R-value for such roof/ceiling assemblies shall be R-38. Insulation shall extend over the top of the wall plate to the outer edge of such plate and shall not be compressed. This reduction of insulation from the requirements of Section R402.1.2 shall be limited to 500 square feet (46 m²) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

Reason: This proposal provides a necessary prescriptive cavity-only wall insulation option for builders and building officials in Climate Zones 6-8. It combines a minimum R-23 wood frame wall R-value with better performing windows (U=0.28) and increased ceiling insulation (R-60), such that equivalent energy performance is achieved. It also modifies Sec. R402.2.1 (Ceilings with attic spaces) and Sec. R402.2.2 (Ceilings without attic spaces) to address framing considerations where R-60 ceiling insulation is required. The proposed R-23 wall cavity insulation level is compatible with 2x6 framing using a variety of cavity insulation types, including several types of batt insulation products and blown-in insulation systems. Note that this proposal does not modify the two existing continuous insulation assemblies...
already listed in Table R402.1.2, nor does it affect the U-factors in Table R402.1.4.

The proposed change provides better energy efficiency performance than the 2018 IECC as shown by both an energy simulation analysis and a Total UA analysis. Both analyses used the U.S. Department of Energy Single Family Prototype for Determining the Cost Effectiveness of the 2018 IECC for house characteristics and square footage. The simulated performance analysis also used the U-factors and modeling guidelines in Sections R405.5.2(1) and R405.5.2(2) of the 2018 IECC for modeling the base or reference home.

New footnote j requires R60 ceiling insulation. This means that Section R402.2.2.1 and R402.2.2.2, which address ceiling insulation to accommodate framing geometry, also need to be modified for consistency.

For R402.2.1, (Ceilings with attic spaces), calculations show that where R-49 insulation covers 100 percent of the ceiling area, including exterior wall plates at full, uncompressed depth, it provides equivalent performance to R-60 with typical eave edge compression. This proposed change was modeled using both a Total UA analysis and Performance based energy modeling. Both models demonstrate energy savings compared to a home built to the base prescriptive path in Tables R402.1.2 and R402.1.4.

4. Component U-Factors used for energy modeling taken from table R402.1.4 of the 2018 IECC.
5. All components not listed, U-factors for energy modeling were taken from table R402.1.4 of the 2018 IECC.

Proposed Section R402.2.2 extends the code's existing recognition of a limited area of reduced insulation to accommodate structural limitations, but it also increases the required stringency of the area of reduced insulation where the Section R402.1.2 base ceiling insulation requirement exceeds R-49.

Currently the code permits R-49 required ceiling insulation, for 20 percent of the ceiling area, to be reduced by R-19 to R-30. As proposed, R-60 insulation, for 20 percent of the ceiling area, would be permitted to be reduced by R-22 to R-38. This is effectively an equivalent reduction in allowable stringency.

The proposed changes were modeled using both a Total UA analysis and Performance based energy modeling. Both models demonstrate energy savings when compared to a home built to the base prescriptive path in Tables R402.1.2 and R402.1.4.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
While it has the potential to decrease the cost of construction, the proposal cannot increase construction costs since it merely adds another prescriptive option for builders.

Proposal # 5185
**Proponent:** William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

**2018 International Energy Conservation Code**

Revise as follows:

**Reason:** The purpose of this code change proposal is to increase energy savings and improve comfort by upgrading and improving slab insulation requirements for climate zones 3-5. Although most other components of the building thermal envelope have improved in recent years, the slab R-value requirements have not improved in any climate zone since at least 2006. The improved values would produce substantial energy cost savings and life cycle cost benefits in all three climate zones:

NR = Not Required. For Si: 1 foot = 304.8 mm.

- **a.** R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
- **b.** The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.
- **c.** Exception: In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements. The SHGC for such skylights does not exceed 0.30.
- **d.** “15/13” means R-15 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “13/13” means R-13 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. Alternatively, compliance with “15/13” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
- **e.** R-5 insulation shall be provided under full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.
- **f.** There are no SHGC requirements in the Marine Zone.
- **g.** Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
- **h.** The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, “13+5” means R-13 cavity insulation plus R-5 continuous insulation.
- **i.** Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.
Insulation can last for many decades and possibly the full useful life of the building, providing consistent comfort and energy saving benefits over that period, so it is particularly important to capture as much cost-effective energy efficiency as possible at construction. This is consistent with the intent of the IECC (R101.3), which is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.”

**Cost Impact:** The code change proposal will increase the cost of construction

The additional insulation required will add to construction costs. However, our analysis shows that the improved efficiency will produce a clear life cycle benefit to the homeowner.

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table, b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

Exception: In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

c. "10'/13'" means R-60 continuous insulation on the interior or exterior of the home or R-30 cavity insulation on the interior of the basement wall. "15'/19'" means R-45 continuous insulation on the interior or exterior of the home or R-15 cavity insulation at the interior of the basement wall. Alternatively, compliance with "15'/19'" shall be R-60 cavity insulation on the interior of the basement wall plus R-30 continuous insulation on the interior or exterior of the home.

d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend beyond the slab.

e. There are no SHGC requirements in the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure P301.1 and Table P301.1.

g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.

h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, "13' + 5'" means R-13 cavity insulation plus R-5 continuous insulation.

i. Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

a. Nonfenestration $U$-factors shall be obtained from measurement, calculation or an approved source.

b. Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall $U$-
factors shall not exceed 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except
Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.

c. In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall $U$-factor shall not exceed 0.360.

Reason: The purpose of this code change proposal is to upgrade and strengthen ceiling insulation requirements in climate zones 2 and 3 by making
the prescriptive values equal to current insulation requirements in climate zone 4 and higher. The proposal will make homes more comfortable and reduce costs for homeowners over the life of the building consistent with the objective of the IECC.
Small improvements to the thermal envelope have a significant impact, particularly in light of the long expected useful life of the home and the thermal
envelope improvements. Insulation in particular may be undisturbed for many decades and possibly the full useful life of the building, providing consistent comfort and energy saving benefits over that period, so it is particularly important to capture as much cost-effective energy efficiency as possible at construction. After all, the intent of the IECC (R101.3) is to "regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building:"

Using DOE's cost-effectiveness methodology, we found these R-value improvements to be cost-effective to the homeowner/consumer with a positive present value life cycle benefit:

<table>

<tr>
<td>2</td>
<td>0.7%</td>
<td>$42</td>
</tr>
<tr>
<td>3</td>
<td>0.9%</td>
<td>$126</td>
</tr>
</tbody>
</table>

These proposed changes are also well within the range specified by the U.S. DOE's insulation guidelines for climate zones 2 and 3 of R30 to R60.
https://www.energy.gov/energysaver/weatherize/insulation

Cost Impact: The code change proposal will increase the cost of construction
Requiring more insulation will increase the cost of construction, but the resulting energy and cost savings will recoup the initial costs and will continue to benefit consumers over the useful life of the home.

NR = Not Required. For St. 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

c. "10'/13" means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. "15'/19" means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. Alternatively, compliance with "15'/19" shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.

d. R-5 insulation shall be provided under the full slab area of heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zone.
f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-13.
h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, "13+5" means R-13 cavity insulation plus R-5 continuous insulation.
Reason: The purpose of this code change proposal is to improve the efficiency of homes in the coldest climate zones by removing an exception that allows weaker floor insulation R-values with no corresponding improvements elsewhere in the building. The current footnote “g” to Table R402.1.2 is a loophole that permits builders to reduce floor insulation (which will lead to a less comfortable home and increased energy costs), simply because of design choices made by the builder. Indeed, this exception allows builders in climate zones 7 and 8 to install half the insulation required by code.

The proposal above does not prohibit a builder from continuing to build floors with any specific floor joist thickness. However, if adequate insulation cannot be installed in the floor cavity, the energy efficiency losses must be accounted for elsewhere in the thermal envelope through a trade-off.

Cost Impact: The code change proposal will increase the cost of construction. However, the proposal will only increase construction costs for homes that might have taken advantage of this exception in the prescriptive path because it will require the installation of insulation sufficient to meet the R-value requirement in Table R402.1.2. However, this change will not increase costs for homes built to all other compliance paths in the IECC, since the footnote exception already does not apply to those homes. We believe the elimination of this exception will provide homeowners with the superior comfort and energy and cost-savings they expect from a code-compliant home.

</tbody>
</table>

**Notes:**

- **a.** Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.
- **b.** Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall U-factors shall not exceed 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.
- **c.** In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall U-factor shall not exceed 0.360.

**Reason:** The purpose of this code change proposal is to improve occupant comfort and save energy by upgrading and strengthening fenestration.
U-factors in climate zones 2 – 4 (by lowering them consistent with modest step improvements in previous code cycles). Fenestration that meets these requirements is cost-effective and will return substantial life cycle savings to homeowners, is already widely available, and is routinely installed in new and existing residential buildings in these climate zones. This proposal also adds a footnote to establish an exception to prescriptive U-factors for fenestration installed at high altitudes (above 4000 feet in elevation) and in regions that require fenestration to be resistant to windborne debris in climate zones 3 – 8. A similar footnote exception was proposed in the last code development cycle and was widely supported by building code officials in these specific regions. Overall, this proposal will improve energy efficiency across much of the nation while allowing reasonable options for fenestration in high-altitude and wind-borne debris regions.

Energy Savings and Cost-Effectiveness - Our analysis, based on the DOE cost-effectiveness methodology, shows the improvements in U-factor to be cost-effective to the consumer with a substantial life cycle benefit:

<table>
<thead>
<tr>
<th>Climate Zone</th>
<th>Annual Energy Cost Savings</th>
<th>Present Value Life Cycle Benefit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0.9%</td>
<td>$273</td>
</tr>
<tr>
<td>3</td>
<td>1.0%</td>
<td>$312</td>
</tr>
<tr>
<td>4</td>
<td>1.1%</td>
<td>$353</td>
</tr>
</tbody>
</table>

Although we believe that the upgrade in the standards will result in no cost increase in most cases, because the new specification is consistent with the standard product already used in the marketplace (as discussed below), for purposes of the life cycle cost analysis above, we used a marginal upgrade cost to be conservative. Even with this approach, the life cycle benefit is robust.

Availability of Compliant Products and Adoption – A 0.30 U-factor requirement is a natural technology level/breakpoint representing a reasonably efficient, double pane, low-e with argon wood or vinyl window. As a result, a number of national and state programs have promoted fenestration U-factors in the range of 0.30 for several years, making these products widely available and already being installed throughout most of the country:

- For example, the American Recovery and Reinvestment Act of 2009 (ARRA) provided a federal income tax credit for fenestration with a U-factor of 0.30 or lower.
- Energy Star has required 0.30 U-factors (or less) for fenestration installed in all but the southernmost climate zones since January 1, 2015. See [https://www.energystar.gov/sites/default/files/ES_Final_V6_Residential_WDS_Spec.pdf](https://www.energystar.gov/sites/default/files/ES_Final_V6_Residential_WDS_Spec.pdf)
- These findings were reinforced through the U.S. DOE Residential Field Studies, which found that even in states in climate zones 2 – 4, with weaker code U-factor requirements, builders were routinely installing fenestration with U-factors around 0.30. See [https://www.energycodes.gov/sites/default/files/documents/Field_Study_120715_Final.pdf](https://www.energycodes.gov/sites/default/files/documents/Field_Study_120715_Final.pdf).

Because of these national trends toward 0.30 U-factor or better fenestration, compliance will not be an issue and in most cases will not even result in an increase in construction costs.

Proposed Exception for Special Circumstances - We believe that the proposed exception is warranted due to the special measures that are taken by glass and/or fenestration manufacturers to address higher altitudes and windborne debris due to high winds.

For example, high altitude products may incorporate breather or capillary tubes in the insulating glass unit to allow pressure equalization for products that will be transported to higher elevations for installation. The pressure equalization can help avoid IG unit failures. However, the capillary tubes eliminate the ability to use certain gas fills commonly used to achieve higher levels of thermal performance. The limited exception proposed above recognizes that circumstance and provides some flexibility for builders in these regions.

Likewise, fenestration designed to withstand windborne debris usually requires special glass which (because of its increased thickness) reduces the gap width in the insulating glass unit. This will affect the thermal performance of the window. To provide some additional flexibility in zones where such fenestration is required, this proposal permits a fenestration U-factor of 0.32 for climate zones 3-8.

In sum, we believe this proposal will implement meaningful energy and cost savings and improved occupant comfort through improved fenestration U-factors that are already available and are routinely being installed by homebuilders.

Cost Impact: The code change proposal will increase the cost of construction. It is possible that requiring more efficient fenestration may, in some cases, increase the cost of construction (and, as a result, we used an upgrade cost in our life cycle cost/benefit analysis), but in any event, the resulting energy and cost savings will overwhelmingly recoup the initial costs and will continue to benefit consumers over the useful life of the home. Moreover, it should also be noted that we would expect that the U-factor reduction will not increase costs in most cases, since the standard market products, with very high market penetration, already typically hit the proposed improved U-factor levels. We also note that for builders in high-altitude or wind-borne debris regions, the new footnote will provide additional flexibility and will likely serve to reduce costs.

NR means Not Required. For SI: 1 foot = 304.8 mm.

- a. *R*-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label design thickness of the insulation, the installed *R*-value of the insulation shall be not less than the *R*-value specified in the table.

- b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

**Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

- c. "10'/13'" means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. "15'/19'" means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. Alternatively, compliance with "15'/19'" shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.

- d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation *R*-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

- e. There are no SHGC requirements in the Marine Zone.

- f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

- g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an *R*-value of R-19.

- h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, "13'-5'" means R-13 cavity insulation plus R-5 continuous insulation.

- i. Mass walls shall be in accordance with Section R402.2.5. The second *R*-value applies where more than half of the insulation is on the interior of the mass wall.

</tbody>
</table>
a. Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.
b. Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall U-factors shall not exceed 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.
c. In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall U-factor shall not exceed 0.360.

**R402.2.1 (IRC N1102.2.1) Ceilings with attic spaces.** Where Section R402.1.2 requires R-38 insulation in the ceiling, installing R-30 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-49 insulation in the ceiling, installing R-38 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-49 insulation wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-60 insulation in the ceiling, installing R-49 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-60 insulation wherever the full height of uncompressed R-49 insulation extends over the wall top plate at the eaves. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

**Reason:** The purpose of this code change proposal is to improve comfort and save energy for homeowners in climate zones 4 - 8 by upgrading and increasing ceiling insulation requirements from R-49 to R-60. Small improvements to the thermal envelope can have a significant beneficial impact, particularly in light of a home’s long expected useful life. Insulation in particular may not be changed for many decades and may last for the full useful life of the building, providing consistent comfort and energy saving benefits over that period. Making long-lived, life cycle cost beneficial improvements is consistent with the intent of the IECC (R101.3), which is to “regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building.” Using DOE’s cost-effectiveness methodology, we found these R-value improvements would provide substantial life cycle cost benefits:

<table>

<td>0.4%</td>
</tr>
</tbody>
</table>

These proposed changes are also within the range specified by the U.S. DOE’s insulation guidelines for these climate zones. https://www.energy.gov/energysaver/weatherize/insulation A home with adequate insulation will maintain more consistent interior temperatures during both heating and cooling seasons and will be more resilient and livable in the event of extreme weather events and power outages.

**Cost Impact:** The code change proposal will increase the cost of construction

Requiring more insulation will increase the cost of construction, but the resulting energy and cost savings will recoup the initial costs and will continue to benefit consumers over the useful life of the home.

NR = Not Required. For SI: 1 foot = 304.8 mm.

- R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
- The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

**Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

- “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-18 cavity insulation at the interior of the basement wall. Alternatively, compliance with “15/19” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
- R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend beyond the slab.
- Basement wall insulation is not required in warm-humid locations as defined by Figure R201.1 and Table R201.1.
- Alternatively, insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.
- The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, “13+5” means R-13 cavity insulation plus R-5 continuous insulation.
- Slab walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

**Reason:** The purpose of this code change proposal is to improve occupant comfort, reduce peak demand and HVAC sizing, and reduce costs for homeowners by establishing a moderate SHGC requirement for fenestration in climate zone 5. While we believe that the vast majority of fenestration installed in climate zone 5 already meets or exceeds this level of efficiency, and the performance path already assumes this same level (a 0.40 SHGC) for climate zone 5, this proposal will encourage the use of fenestration with proven efficiency and comfort benefits.

- **Comfort** – A window that combines both a low U-factor (which is already required for climate zone 5) with a low SHGC will help reduce the volatility of interior temperature swings and better maintain reasonable occupant comfort. According to the Efficient Windows Collaborative, based on an analysis completed by Lawrence Berkeley National Laboratory, windows with lower SHGCs reduce the amount of solar radiation passing through the glass, which will reduce the likelihood of discomfort of occupants. See https://www.efficientwindows.org/comfort.php. An uncomfortable occupant due to excessive solar gain through windows is more likely to adjust the thermostat to a cooler temperature over the course of the day in response, thereby increasing peak demand and energy use.

Although energy modeling software does not typically capture the likelihood of occupant response to discomfort, anyone who has lived or worked in
a building with excessive solar gain through fenestration, knows that this can lead occupants to adjust the thermostat. The energy impact of adjusting the thermostat is substantial. The following table shows the increased energy use that results from adjusting the thermostat down a single degree in a code-compliant house in each climate zone:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Weighted</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1 Degree Cooling</td>
<td>3.0%</td>
<td>7.8%</td>
<td>5.3%</td>
<td>3.9%</td>
<td>2.6%</td>
<td>1.8%</td>
<td>1.4%</td>
<td>0.7%</td>
<td>0.4%</td>
</tr>
</tbody>
</table>

Obviously, if an uncomfortable occupant adjusts the thermostat 2 or 3 degrees, the impact will be far higher.

**Peak Demand and HVAC Sizing Savings** – Low-SHGC fenestration helps reduce both the home and utility peak electric demand, providing a range of benefits for homeowners and communities. Low-SHGC fenestration helps reduce the need for air conditioning during peak hours when electricity is more scarce and more expensive. Reduced cooling needs can allow for the installation of smaller cooling equipment, benefitting the homeowner by lowering costs at construction and every time the air conditioning unit is replaced. Reduced peak electric demand for each home will also help curb the overall increases in utility peak electric demand, reducing costs and negative environmental impacts associated with installing and operating peak electric generation. See U.S. Department of Energy, *Measure Guideline: Energy Efficient Window Performance and Selection*, at 49, available at https://www.nrel.gov/docs/fy13osti/55444.pdf.

**Market Availability** - Given the U-factor requirement in climate zone 5 (currently 0.30), the overwhelming majority of products being installed in this climate are already well under a 0.40 SHGC. Indeed, according to a 2015 U.S. DOE field study of homes in Pennsylvania (which had no SHGC requirement), 100% of the observed fenestration SHGC was below 0.40. In fact, the highest SHGC observed was 0.32. See https://www.energycodes.gov/compliance/energy-code-field-studies. While this study was limited to one state and a limited sample, we have seen no evidence that the circumstances are different in other climate zone 5 states. Given the ubiquity of low-SHGC fenestration in climate zone 5, we believe that this proposal will not significantly change, but merely recognize practices already implemented by homebuilders.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

We believe that the vast majority of windows being installed in climate zone 5 already meet this SHGC level, and for any that do not, there are many standard products in the market that will meet it for no additional cost (the vast majority of windows that meet the U-factors specified for climate zone 5 already have a lower SHGC than 0.40; the lower SHGC typically comes with the lower U-factor). A lower SHGC may also provide the opportunity to reduce the size of the HVAC system, thereby reducing construction cost. As a result, any increased or decreased cost impact is dependent on specific circumstances and is uncertain.

Proposal # 3987

RE37-19
**2018 International Energy Conservation Code**

Revise as follows:

R402.1.2 (IRC N1102.1.2) **Insulation and fenestration criteria.** The building thermal envelope shall meet the requirements of Table R402.1.2, based on the climate zone specified in Chapter 3. Assemblies shall have a U-factor equal to or less than that specified in Table R402.1.2. Fenestration shall have a U-factor and glazed fenestration SHGC equal to or less than specified in Table R402.1.2.

Add new text as follows:

R402.1.3 (IRC N1102.1.3) **R-value alternative.** Assemblies with R-value of insulation materials equal to or greater than that specified in Table R402.1.3 shall be an alternative to the U-factor in Table R402.1.2.

Revise as follows:

</tbody>
</table>

a. Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.
b. Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall U-factor shall not exceed 0.17 in Climate Zones 1, 2, 4 in Climate Zone 1, 0.12 in Climate Zone 2, 0.087 in Climate Zone 4 except Marine, 0.085 in Climate Zones 5 and Marine 4, and 0.077 in Climate Zones 6 through 8.
c. In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall U-factor shall not exceed 0.36.
d. The SHGC column applies to all glazed fenestration.

**Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.36.

e. There are no SHGC requirements in the Marine Zone.

Portions of table not shown remain unchanged.
R402.1.3 (IRC N1102.1.3) R402.1.4 (IRC N1102.1.4) R-value computation. Insulation material used in layers, such as framing cavity insulation or continuous insulation, shall be summed to compute the corresponding component R-value. The manufacturer’s settled R-value shall be used for blown-in insulation. Computed R-values shall not include an R-value for other building materials or air films. Where insulated siding is used for the purpose of complying with the continuous insulation requirements of Table R402.1.2, the manufacturer’s labeled R-value for the insulated siding shall be reduced by R-0.6.

R402.1.4 (IRC N1102.1.4) U-factor alternative. An assembly with a U-factor equal to or less than that specified in Table R402.1.4 shall be an alternative to the R-value in Table R402.1.2.

R402.1.5 (IRC N1102.1.5) Total UA alternative. Where the total building thermal envelope UA, the sum of U-factor times assembly area, is less than or equal to the total UA resulting from multiplying the U-factors in Table R402.1.4 by the same assembly area as in the proposed building, the building shall be considered to be in compliance with Table R402.1.2. The UA calculation shall be performed using a method consistent with the ASHRAE Handbook of Fundamentals and shall include the thermal bridging effects of framing materials. In addition to UA compliance, the SHGC requirements shall be met.

Reason: This proposal does not change the stringency of the R-value and U-factor requirements. This proposal organizes the envelope thermal requirements such that the basis of performance (and any other means of compliance) is founded on U-factors which completely define an assembly’s performance. The R-value approach is kept to provide pre-determined solutions (easy to look up) and it is based on the U-factor requirements as it should be (and the same would apply to any other equivalent R-value solution that one might propose as an alternative for compliance). This approach does not change the prescriptive R-value approach or the ability to use it for simple solutions. Instead, it better ensures that the R-values used are a derivative of the intended performance levels that are non-material specific and represented by the assembly U-factors. Also, fenestration and SHGC requirements are included in the U-factor table because they are currently omitted. The SHGC values (and footnotes) are consistent with those in the current R-value table.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal does not change the stringency of R-value and U-factor requirements, but it will ensure that alternate R-value solutions are appropriately based on the U-factor requirements, including those that are predetermined in the R-value table which is kept to maintain a simple means of compliance.

NR = Not Required. For SI, 1 foot = 304.8 mm.
\(a\) R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
\(b\) The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

**Exception:** In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

\(c\) “10’/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15’/19” means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the
R402.2.1 (IRC N1102.2.1) Ceilings with attic spaces. Where Section R402.1.2 requires R-38 insulation in the ceiling, installing R-30 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-49 insulation in the ceiling, installing R-38 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-49 wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-60 insulation in the ceiling, installing R-49 over 100 percent of the ceiling area requiring insulation shall satisfy the requirement for R-60 insulation wherever the full height of uncompressed R-49 insulation extends over the wall top plate at the eaves. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

Reason: This proposal will save energy by providing a critically needed prescriptive cavity-only wall insulation option for Climate Zones 6-8 for the many builders and building officials that rely on the prescriptive table. This new option provides equivalent energy performance by combining a minimum R23 wood frame wall R-value with better performing windows (U=0.28) and increased ceiling insulation (R60), such that equivalent energy performance is achieved.

The proposed R23 wall cavity insulation level is compatible with 2x6 framing using a variety of cavity insulation types, including several types of batt insulation products and blown-in insulation systems.

R402.2.2 (IRC N1102.2.2) Ceilings without attic spaces. Where Section R402.1.2 requires R-38 insulation in the ceiling and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the minimum required insulation R-value for such roof/ceiling assemblies shall be R-30. Where Section R402.1.2 requires R-49 insulation in the ceiling and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the required insulation R-value for such roof/ceiling assemblies shall be R38. Insulation shall extend over the top of the wall plate to the outer edge of such plate and shall not be compressed. This reduction of insulation from the requirements of Section R402.1.2 shall be limited to 500 square feet (46 m2) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

Reason: This proposal will save energy by providing a critically needed prescriptive cavity-only wall insulation option for Climate Zones 6-8 for the many builders and building officials that rely on the prescriptive table. This new option provides equivalent energy performance by combining a minimum R23 wood frame wall R-value with better performing windows (U=0.28) and increased ceiling insulation (R60), such that equivalent energy performance is achieved.

The proposed R23 wall cavity insulation level is compatible with 2x6 framing using a variety of cavity insulation types, including several types of batt insulation products and blown-in insulation systems.
Verifying compliance in the field is easily done by checking the fenestration labels and insulation certificates and markers required by Sec. R303.

Note that this proposal does not modify the two existing continuous insulation assemblies already listed in Table R402.1.2, nor does it affect the U-factors in Table R402.1.4.

The proposed formatting of Table R402.1.2 in this proposal is identical to that of RE28-16 PC1 which was passed overwhelmingly by the assembly at the public comment hearings in Kansas City in 2016 before failing to achieve the supermajority by a single vote in online voting https://www.iccsafe.org/wp-content/uploads/2016-GroupB-Final-Action-Results-OGCV.pdf.

The energy efficiency of the proposed change was shown to provide better performance than the 2018 IECC using both an energy simulation analysis and a Total UA, REScheck analysis. Both analyses demonstrated better performance than the 2018 IECC. Both analyses used the U.S. Department of Energy Single Family Prototype for Determining the Cost Effectiveness of the 2018 IECC for house characteristics and square footage, in addition the simulated performance analysis uses U-factors and modeling guidelines in Sections R405.5.2(1) and R405.5.2(2) of the 2018 IECC for modeling the base or reference home.

1. Square footages and attributes taken from the US DOE Single Family Prototype for Determining the Cost Effectiveness of the 2018 IECC.
2. Component U-factors calculated in accordance with the 2015 ASHRAE Handbook of Fundamentals.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal offers an optional path for prescriptive envelope compliance. Because it is optional it cannot raise the cost of construction; a builder will choose whatever option they believe provides the greatest benefit for the cost.

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.
b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

c. "10/13" means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. "15/19" means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. Alternatively, compliance with "15/19" shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation R-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.
e. There are no SHGC requirements in the Marine Zone.
f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
g. Alternatively, Insulation sufficient to fill the framing cavity and providing not less than an R-value of R-19.
h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, "13+5" means R-13 cavity insulation plus R-5 continuous insulation.
Reason: This proposal is an energy neutral change based on calculations from ASHRAE. Insulation that is R-19 that is compressed in a 2 x 6 wall with stud spacing at 24 o.c. performs like R-18. The ASHRAE Handbook of Fundamentals and ASHRAE Transaction 1995 Volume 101, Part 2 assumes that wood framed walls have a framing factor of 25%. Meaning 25 percent of the wall area consists of structural framing members and the remainder of the wall is a cavity suitable for installing insulation. When calculating the U-factor for a wall assembly, a high framing factor increases the overall assembly U-Factor. Reducing the framing factor will also provide an increase in the thermal performance of the wall.

This proposal provides an option for a thermally equivalent tradeoff for 2x6 wall assemblies which have reduced framing factors and insulation performing like a R-18 insulator.

Below are the calculations showing equal U-Factors for both assemblies (0.060).

i. Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

j. R-18 insulation shall be permitted in place of the R-20 requirement provided that the wall framing factor is 20% or less of exterior walls having 24 inch on center nominal vertical stud spacing.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal will offer an optional way for compliance, by allowing a framing and insulation alternative to what is currently in the code without reducing the overall efficiency.

- **a.** Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.
- **b.** Mass walls shall be in accordance with Section R402.2.5. Where more than half the insulation is on the interior, the mass wall U-factors shall not exceed 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.
- **c.** In warm-humid locations as defined by Figure R301.1 and Table R301.1, the basement wall U-factor shall not exceed 0.360.
- **d.** A maximum U-factor of 0.32 shall apply in Climate Zone Marine 4 and Climate Zones 5 through 8 to vertical fenestration products installed in buildings located:

---

i. Mass walls shall be in accordance with Section R402.2.5. The second R-value applies where more than half of the insulation is on the interior of the mass wall.

ii. A maximum U-factor of 0.32 shall apply in Climate Zones 5 through 8 to vertical fenestration products installed in buildings located:

1. Above 4000 feet in elevation above sea level, or
2. In windstorm debris regions where protection of openings is required under Section R301.2.1.2 of the International Residential Code.
1. Above 4000 feet in elevation above sea level, or
2. In windborne debris regions where protection of openings is required under Section R301.2.1.2 of the International Residential Code.

**Reason:** High altitude products generally require breather or capillary tubes in the insulating glass unit to allow pressure equalization when the products are transported to higher elevations for installation. The pressure equalization is necessary to avoid breakage. However, the tubes eliminate the ability to use gas fills commonly used to achieve higher levels of thermal performance. Meanwhile, windborne debris protection requirements for fenestration are typically met by the use of laminated glass which reduces the gap width in the insulating glass unit and thus the thermal performance. This footnote provides a reasonably limited and needed exception for products installed above 4000 ft above sea level in climate zones Marine4 zones 5-8, and for products that must meet windborne debris protection requirements.

**Cost Impact:** The code change proposal will decrease the cost of construction. This will avoid the need for costly redesign of products, e.g., larger frame sizes for impact resistant fenestration, or the need for fenestration products to be installed above 4000 ft to be manufactured in a location above 4000 ft.
Proponent: Darren Meyers, P.E., IECC_LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revised as follows:

R402.2.1 (IRC N1102.2.1) Ceilings with attic spaces. Where Section R402.1.2 requires R-38 insulation in the ceiling attic, installing R-30 over 100 percent of the ceiling attic area requiring insulation shall satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Where Section R402.1.2 requires R-49 insulation in the ceiling attic, installing R-38 over 100 percent of the ceiling attic area requiring insulation shall satisfy the requirement for R-49 insulation wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

R402.2.2 (IRC N1102.2.2) Ceilings without attic spaces. Where Section R402.1.2 requires insulation R-values greater than R-30 in the ceiling interstitial space above a ceiling and below the structural roof deck and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the minimum required insulation R-value for such roof/ceiling assemblies shall be R-30. Insulation shall extend over the top of the wall plate to the outer edge of such plate and shall not be compressed. This reduction of insulation from the requirements of Section R402.1.2 shall be limited to 500 square feet (46 m²) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the U-factor alternative approach in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

Reason: This code change proposal is intended to provide clarity consistent with roofing terminology used every day by roofing industry- and design-professionals across the country.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification and consistency across the ICC Family of International Codes.
2018 International Energy Conservation Code

Revise as follows:

R103.2 (IRC N1101.5) Information on construction documents. Construction documents shall be drawn to scale on suitable material. Electronic media documents are permitted to be submitted where approved by the code official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include the following as applicable:

1. Insulation materials and their R-values.
2. Fenestration U-factors and solar heat gain coefficients (SHGC).
3. Area-weighted U-factor and solar heat gain coefficients (SHGC) calculations.
4. Mechanical system design criteria.
5. Mechanical and service water-heating systems and equipment types, sizes and efficiencies.
6. Equipment and system controls.
7. Duct sealing, duct and pipe insulation and location.
8. Air sealing details.
9. Batch sampling plan (where applicable).

SECTION R202 (IRC N1101.6) GENERAL DEFINITIONS

Add new definition as follows:

BATCH SAMPLING. Verification of energy code requirements when fewer than 100 percent of every dwelling or dwelling unit, within a sampled project are inspected, tested, or modeled for compliance.

Add new text as follows:

R401.2.2 (IRC N1101.13.2) Batch sampling. Batch sampling to determine energy code compliance shall only be allowed for stacked multiple-family dwelling unit projects within the same subdivision or community.

Exceptions:

1. Where sampling of energy compliance items for other than sections R402.4 and R403.3.3, an approved sampling plan shall be included in the construction documents and approved by the code official.
2. Where sampling is proposed for other than stacked multiple-family dwelling unit projects, an approved sampling plan shall be included in the construction documents and approved by the code official.

R401.2.2.1 (N1101.13.2.2.1) Sampling process. The sampling process shall follow these steps:
1. After five consecutive dwellings or dwelling units demonstrate compliance with the code without an incidence of failure, then only one dwelling or dwelling unit in subsequent batches of five dwelling units is required to demonstrate compliance through testing and inspection.
2. The remaining four units in the sampling batch shall be considered to be in compliance with the code when the one sampled unit in the batch of five dwelling units has demonstrated compliance.
3. Where the one dwelling or dwelling unit tested and inspected in the batch of five fails to demonstrate compliance with the code then that unit and 3 consecutive dwellings or dwelling units shall demonstrate compliance without incidence of failure before batch sampling is allowed to continue.

Exception: An approved sampling plan shall be used as an alternative to Section R401.2.2.1.

Revise as follows:

R405.4.2 (IRC N1105.4.2) Compliance report. Compliance software tools shall generate a report that documents that the proposed design complies with Section R405.3. A compliance report on the proposed design shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based on the as-built condition of the building shall be submitted to the code official before a certificate of occupancy is issued. Batch sampling of buildings to determine energy code compliance shall only be allowed for stacked multiple-family units. Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. Where the proposed design of a building could be built on different sites where the cardinal orientation of the building on each site is different, compliance of the proposed design for the purposes of...
the application for the building permit shall be based on the worst-case orientation, worst-case configuration, worst-case building air leakage and worst-case duct leakage. Such worst-case parameters shall be used as inputs to the compliance software for energy analysis.

**Reason:** Currently, sampling is only addressed within the Simulated Performance Path section R405 of the IECC. It states, “Batch sampling of buildings to determine energy code compliance shall only be allowed for stacked multiple-family units.” Narrowing the allowance for sampling to stacked multi-family units makes a lot of sense but narrowing sampling to only the Simulated Performance path does not. This proposal broadens the ability to sample dwelling units regardless of the pathway used to navigate the IECC.

In researching this proposal, it became evident that sampling means something different to the code compliance community than it does to the verification and builder program community. My discussions with the code compliance community indicated that they believe that sampling is only a tool that is used for lessening the requirement of blower door and duct leakage testing every permitted dwelling unit. The verification and builder program community, on the other hand, uses sampling to verify compliance of any requirement of compliance. Therefore, this proposal states that sampling used for anything other than blower door or duct leakage testing must have a sampling plan submitted at permitting that is approved by the authority having jurisdiction. In this way, it is ultimately up to the jurisdiction to determine their comfort level with the use of sampling for other code compliance feature and building types than diagnostic testing and stacked multi-family dwelling units.

Currently, the code does not define in any way what sampling means. The second half of this proposal defines the minimum requirements for sampling, which not only offers guidance to the jurisdiction for what to expect but also offers a baseline for which to assess the merits of submitted sampling plans which may be submitted to potentially broaden the scope of what could be sampled.

In specific markets, such as Phoenix Arizona, sampling is a common occurrence and in others, it never occurs. This proposal ensures that regardless of where it is used that there is a common understanding of what it is and how it can be used for code compliance in comparison to compliance with programs such as EnergyStar or LEED for homes.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

It is not clear how to assess the cost impact of a proposal like this as it depends completely on the quality of the installation of the code required item. If everything passes inspection the first time it can save money due to requiring fewer inspections, but if something fails it must be tested 3 more times and it could increase cost. The most important aspect of the proposal is not associated with cost it is associated with the ability to use sampling regardless of the compliance path chosen.
IECC: R402.2.3 (IRC N1102.2.3)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.3 (IRC N1102.2.3) Eave baffle. For air-permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. Baffles shall maintain a net free area opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material. The baffle shall be installed to the outer edge of the exterior wall top plate so as to provide maximum space for attic insulation coverage over the top plate. Where soffit venting is not continuous, baffles shall be installed continuously to prevent ventilation air in the eave soffit from bypassing the baffle.

Reason: The objective of the attic eave baffles is to provide a continuous pathway for air flow from the eave vent to the ridge or pot vent located higher up on the roof without allowing air to migrate through the insulation that is used, thus reducing the insulations ability to retard heat flow. In order to ventilate the attic according to the IRC section R806.2 a minimum net free area is called out. For air to go out of the roof vent air must enter through the eave vent and if the net free area is not equal at the eave vent and the path the air takes from the eave to the roof vent above the insulation, the IRC required ventilation can not occur. Thus, the inclusion of the language "net free area" for the defined ventilation created with the baffle.

In the IECC section R402.2.2 the code states “Insulation shall extend over the top plate of the wall plate to the outer edge of such plate and shall not be compressed.” This section is discussing installation not related R-value requirements that may change depending on the IECC compliance pathway. This proposal adds an installation instruction to better ensure that attic insulation can be installed, as much as possible over, the top plate to achieve the energy savings of the installation.

IRC Section R806.3 states that, “Where eave or cornice vents are installed, blocking, bridging and insulation shall not block the free flow of air.” When air enters non-continuous attic eave vents and fills the eave with air that air travels both through the designated space created by the eave baffles and through the surrounding insulation in adjacent bays. The insulation is slowing or “blocking” the free flow of air that section R806.3 is trying to preserve. In addition, ventilated attics use the depth of the installed insulation to overcome the performance implications of not being able to enclose the insulation on the attic ventilation side. The intrusion of eave vent ventilation into the attic insulation at the drywall plane separating the attic from conditioned space below degrades the ability of the insulation to inhibit the flow of energy and achieve the desired R-value. This proposal uses continuous baffles to better ensure that eave ventilation passes cleanly over the top of all installed insulation bettering the performance of the ventilation system and the installed insulation.

Cost Impact: The code change proposal will increase the cost of construction

Depending on the design of the attic eave ventilation system minimal cost increases could be incurred from requiring the installation of continuous soffit baffles. However, cost of ownership would go down in relationship to the first cost as the ability of the insulation to reduce heat lose would increase.

Proposal # 4800
2018 International Energy Conservation Code

Revise as follows:

R402.2.3 (IRC N1102.2.3) Eave baffle. **(Mandatory)** For air-permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. Baffles shall maintain an opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material.

**Reason:** Because Section R402.2 Specific Insulation Requirements (Prescriptive), is marked prescriptive R402.2.3 automatically becomes prescriptive but there is no reason that Eave Baffles should be allowed to be traded off. We understand that the SEHPCAC committee is putting forth a proposal to revise all of the prescriptive verses mandatory requirements, which we approve of, but it may not pass, so we are doing this as a back up plan.

**Cost Impact:** The code change proposal will increase the cost of construction. Truly there should be no cost impact because eave baffles should have always been installed. However, if someone was trading them off there would be a cost for installing a baffle now. The cost is dependent on the material used, it could be as simple as a piece of cardboard. So, the cost would be for the labor.
**R402.2.4 (IRC N1102.4) Access hatches and doors.** Access hatches and doors from conditioned to unconditioned spaces such as attics and crawlspaces shall be insulated to the same level required for the wall or ceiling R-value in Table R402.1.2 in which they are installed.

**Exception:** Vertical doors providing access from conditioned spaces to unconditioned spaces that comply with the fenestration requirements of Table R402.1.2 based on the applicable climate zone specified in Chapter 3.

**Revise as follows:**

**R402.2.4 (IRC N1102.4) R402.2.4.1 (IRC N1102.4.1) Access hatches and doors: doors installation (Mandatory).** Access hatches and doors from conditioned spaces to unconditioned spaces such as attics and crawl spaces shall have weatherstripping and be insulated to a level equivalent to the insulation on the surrounding surfaces. Weatherstripping Access that prevents damaging or compressing the insulation shall be provided to all equipment. Where loose-fill insulation is installed, a wood-framed or equivalent baffle or retainer shall be installed to prevent the loose-fill insulation from spilling into the living space when the attic access is opened. The baffle or retainer shall provide a permanent means of maintaining the installed R-value of the loose-fill insulation.

**Exception:** Vertical doors providing access from conditioned spaces to unconditioned spaces that comply with the fenestration requirements of Table R402.1.2 based on the applicable climate zone specified in Chapter 3.

**Reason:** R402.2.4 includes both prescriptive provisions (required insulation levels) and non-tradeable (mandatory) installation specifications. This proposal does not add new requirements; rather, it separates the prescriptive and mandatory provisions into separate sections.

The insulation installation requirements of new Sec. R402.2.4.1 have no value or metric that can be used for modeling purposes; they are non-tradeable (mandatory).

Note that the SEHPCAC has a proposal to eliminate the use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful, ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will increase the cost of construction

The code change may increase construction costs for a subset of buildings that may have been designed using the Total Building Performance or EIR compliance methods that included did not include weatherstripping or baffles around the applicable hatches and doors.
**RE47-19**

IECC: R402.2.4 (IRC N1102.2.4)

Proponent: Stephen Skalko, representing Marwin Company (svskalko@svskalko-pe.com)

2018 International Energy Conservation Code

Revise as follows:

**R402.2.4 (IRC N1102.2.4) Access hatches and doors.** Access doors from *conditioned spaces* to *unconditioned spaces* such as attics and crawl spaces shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access that prevents damaging or compressing the insulation shall be provided to all equipment. Where loose-fill insulation is installed, a wood-framed or equivalent baffle or retainer shall be installed to prevent the loose-fill insulation from spilling into the living space when the attic access is opened. The baffle or retainer shall provide a permanent means of maintaining the installed R-value of the loose-fill insulation.

**Exception:**

1. Vertical doors providing access from *conditioned spaces* to *unconditioned spaces* that comply with the fenestration requirements of Table R402.1.2 based on the applicable climate zone specified in Chapter 3.
2. In Climate Zones 1 through 4 horizontal pull-down stair-type access hatches in ceiling assemblies that provide access from *conditioned* to *unconditioned spaces* shall not be required to comply with the insulation level of the surrounding surfaces provided the hatch meets all of the following:
   1. The average U-factor of the hatch shall not exceed U-0.10 or have an average insulation R-value less than R-10.
   2. Not less than 75 percent of the panel area shall have an insulation R-value of at least R-13.
   3. The net area of the framed opening shall be less than or equal to 13.5 square feet, and
   4. The perimeter of the hatch edge shall be weatherstripped.

The reduction shall not apply to the U-factor alternative approach in Section R402.1.4 or the total UA alternative in Section R402.1.5.

**Reason:** A code change similar to this proposal was submitted to the IECC and IRC during the 2016 Group B code cycle (RE50-16). At the Code Action Hearing in Louisville, KY the IECC Code Development Committee (CDC) saw the logic of the proposal and recommended the change for Approval As Submitted. The CDC reason given was:

*The practical implications outweigh the minimal loss of insulation R-value. Experience with products that can comply with these requirements is a superior method as compared what has been done in the past and provides for a long-term solution.*

Their reason is consistent with our experience that the added insulation requirement in section R402.2.4 (N1102.2.4) is frequently achieved with “field crafted detachable apparatuses”. Unfortunately, over time these are commonly discarded or worse, set aside compressing adjacent ceiling insulation thus defeating the intended benefit. The objective of this proposal is to address this field modification issue and provide for a more permanent installed solution.

During the 2015 ICC code development cycle for the IRC and the IECC an exception was added to the ceiling insulation requirements for vertical doors providing access to attic areas in IECC Section R402.2.4 and IRC Section N1102.2.4. This exception was based on the premise that vertical attic access doors between conditioned and unconditioned spaces can be treated as fenestration. Horizontally positioned attic access hatches are a similar issue. These horizontal hatches are being required to have insulation levels that match the surrounding ceiling which is significantly more stringent than skylight fenestration products located in these same ceiling assemblies.

For example, in Table R402.1.2 (N1102.1.2) Skylights are required to meet a U-factor that ranges from 0.75 in Climate Zone 1 to 0.55 in Climate Zone 8. In addition, Section R402.3.3 (N1102.3.3) allows up to 15 square feet of the fenestration per dwelling unit (which includes skylights) to be exempt from the requirements in Table R402.1.2 (N1102.1.2). It does not make sense to require R-30 to R-49 insulation for a pull down stair type access hatch in an insulated ceiling when one can have a skylight up to 15 square feet in area that is exempt from the envelope requirements or that has a U-FACTOR of 0.55-0.75 (less than R-2). Insulating pull down stair access hatches to the levels specified in N1102.2.4 (R402.2.4), compared to the skylights insulation requirements is expensive, and in many cases not practical.

Because affordable, pre-manufactured pull-down stair access systems are not readily available to meet the R-30 to R-49 target field customization of access hatches is sometimes employed to achieve these performance levels. Inspection and verification for compliance becomes a challenge. As noted previously, long term system performance of these field customized entry devices may also vary. Commonly these “field crafted detachable apparatuses” are designed to be removed for attic access and placed on the adjacent attic joists. This results in the insulation being compressed thus reducing its effectiveness. Also providing sufficient air sealing around the hatch that remains durable long term is difficult. Finally, removal of the insulated covers for access may present a safety hazard to service personnel, inspectors and building owners having to stand on ladders while removing the hatches.
Quality standardized manufactured pull down stair systems however provide a safer, permanent access with proven performance for the life of the structure. Factory built energy rated access systems provide consistent air sealing performance and ensure consistent energy performance while helping to maintain air quality through reduced air infiltration.

This proposal provides a solution by permitting a reasonable reduction in the insulation values for pull down stair access hatches that are less than or equal to 13.5 square feet (approximately 30” X 64”) in attic ceilings. This maximum size accommodates most manufactured products available. The U-value specified at U-0.10 is less stringent than the U-values specified for the insulated ceilings but is far more stringent than those permitted for skylights in all Climate Zones. Too the size limit is more stringent than that permitted for skylights which can have one unit up to 15 square feet in size exempted from the code requirements while all other skylights are less stringent than the pull down stair assembly proposed. Finally, the proposal also does not allow this reduction to be factored into the U-Factor alternative calculation procedure in R4002.1.4 (N1102.1.4) or the total UA alternative procedure in R402.1.5 (N1102.1.5). This is consistent with the limitations in Section R402.2.1 (N1102.2.1) for ceilings with attic spaces and in Section R402.3.3 (N1102.3.3) for skylights.

Though the previous code change RE50-16 was recommended for approval as submitted a public comment was submitted. At the Public Comment Hearing (PCH) in Kansas City, MO the commenter raised concerns about the impact of such reduced insulation levels in cold climates. The membership overturned the action of the committee and RE50-16 was disapproved.

The intent of this proposal is the same as the original proposal previously approved by the IECC Code Development Committee with two basic improvements.

1. The criteria that horizontal pull-down stair-type access hatches must meet has been formatted in a list format to aid the code user in determining the requirements to be met by this exception.

2. The reduced insulation level for these horizontal pull-down stair-type access hatches is limited to Climate Zones 1-4 in response to previous objections for this exception in cold climates.

Recommend the IECC Code Development Committee again take action to Approve As Submitted.

Cost Impact: The code change proposal will decrease the cost of construction
The reduced cost of field installed apparatuses and insulation will offset the cost of the pull-down stair
IECC: R402.2.4 (IRC N1102.2.4)

Proponent: Shaunna Mozingo, City of Westminster, representing Colorado Chapter of ICC Energy Code Development Committee
(smозingo@cityofwestminster.us)

2018 International Energy Conservation Code

Revise as follows:

R402.2.4 (IRC N1102.2.4) Access hatches and doors. (Mandatory) Access doors from conditioned spaces to unconditioned spaces such as attics and crawl spaces shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access that prevents damaging or compressing the insulation shall be provided to all equipment. Where loose-fill insulation is installed, a wood-framed or equivalent baffle or retainer shall be installed to prevent the loose-fill insulation from spilling into the living space when the attic access is opened. The baffle or retainer shall provide a permanent means of maintaining the installed Rvalue of the loose-fill insulation.

Exception: Vertical doors providing access from conditioned spaces to unconditioned spaces that comply with the fenestration requirements of Table R402.1.2 based on the applicable climate zone specified in Chapter 3.

Reason: Because Section R402.2 Specific Insulation Requirements (Prescriptive), is marked prescriptive R402.2.4 automatically becomes prescriptive but there is no reason that Access Hatches and Door Sealing and Insulation level should be allowed to be traded off. We understand that the SEHPCAC committee is putting forth a proposal to revise all of the prescriptive verses mandatory requirements, which we approve of, but it may not pass, so we are doing this as a back up plan.

Cost Impact: The code change proposal will increase the cost of construction
There is no reason that this should increase cost because it's mandatory that you seal the thermal envelope, and you always have to provide insulation in a vented attic, the level just depends on which path you choose. But, people will argue that since it was prescriptive you didn't really have to do it, so there could be a charge for weather stripping and insulation, amount dependent on material used.

Proposal # 5315
IECC: R402.2.4 (IRC N1102.2.4)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.4 (IRC N1102.2.4) Access hatches hatch doors and doors, insulation retention. Access Vertical or horizontal access doors from conditioned spaces to unconditioned spaces such as attics and crawl spaces shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access that prevents damaging or compressing the insulation shall be provided to all equipment. Where loose-fill insulation is installed, a wood-framed or equivalent baffle, retainer, or retainer dam shall be installed to prevent the loose-fill insulation from spilling into the living space when the attic access is opened, from higher to lower sections of the attic, and from attics covering conditioned spaces to unconditioned spaces. The baffle or retainer shall provide a permanent means of maintaining the installed R-value of the loose-fill insulation.

Exception: Vertical doors providing access from conditioned spaces to unconditioned spaces that comply with the fenestration requirements of Table R402.1.2 based on the applicable climate zone specified in Chapter 3.

Reason: This section of the code is solely about the installation of insulation in the attic and retaining it in its installed location to ensure that it performs as intended by the manufacturer. The use of wooden or equivalent baffle retainer or insulation dam to hold insulation in place at the attic hatch needs to be expanded to include insulation that is installed in raised ceilings or separating conditioned from unconditioned spaces. The inclusion of additional language to this proposal improves how insulation will perform when installed in these locations.

Cost Impact: The code change proposal will increase the cost of construction. Attention to detail in installation dams and baffles will initially take slightly more labor but will be negligible once methods are in place to do it right the first time. The cost of ownership and cost of builder warranty is lowered.

Proposal # 4799
2018 International Energy Conservation Code

Revise as follows:

R402.2.5 (IRC N1102.2.5) Mass walls. Mass walls where used as a component of the building thermal envelope shall be one of the following:

1. Above-ground walls of concrete block, concrete, insulated concrete form, masonry cavity, brick but not brick veneer, adobe, compressed earth block, rammed earth, solid timber, mass timber, or solid logs.

2. Any wall having a heat capacity greater than or equal to 6 Btu/ft² °F (123 kJ/m² K).

Add new definition as follows:

**MASS TIMBER** Structural elements of Type IV construction primarily of solid, built-up, panelized or engineered wood products that meet minimum cross-section dimensions of Type IV construction, as defined in the International Building Code.

**Reason:** This new term, as approved in the 2018 Group A Code Hearings for the IBC, adds a new type of construction into the residential provisions of the IECC. By adding this definition, the subsequent definitions of mass walls can be updated to include mass walls. Addition of mass timber into the prescriptive list of materials that are considered mass walls will make it possible for any material meeting the IBC definition of mass timber to be used without additional testing for heat capacity.

**Cost Impact:** The code change proposal will decrease the cost of construction.

By adding mass timber into the prescriptive list of materials constituting a mass wall, builders will be able to use mass timber for building envelope features without requiring additional testing for heat capacity of the material. By saving on this testing, the cost of construction is expected to decrease.
**2018 International Energy Conservation Code**

Revises as follows:

</table>

---

*a.* The first value is cavity insulation R-value, the second value is continuous insulation R-value. Therefore, for example, “R-30+3” means R-30 cavity insulation plus R-3 continuous insulation.

*b.* Insulation exceeding the height of the framing shall cover the framing.

**Reason:** Commenter’s Reason: This proposal expands the listing for cold-formed steel equivalent R-values in order to coordinate with Tables R402.1.2 and N1102.1.2 entitled “Insulation and Fenestration Requirements by Component”.

**History and Selection of Methodology:** The RESCheck methodology was originally selected for determining equivalency since its methodology for calculating wood and steel framed U-factors has served as the basis for U-factor calculations of these assemblies since the publication of the 2004 IECC Supplement Edition. This approach was again used for consistency in this code change proposal.

**Details of Calculations and Assumptions:** The U-factors from Tables R402.1.4 (and N1102.1.4) for wood framed walls were used as the benchmark to determine the equivalent insulation (Cavity and continuous) R-values for cold-formed steel framing. The cold-formed steel framed walls at 16” o.c. and 24” o.c. were then calculated where cavity and exterior insulation were added in order to achieve near equivalent U-factors as
for wood framed wall assemblies. This resulted in R-values and U-factors for cold-formed steel framed walls that can be considered comparable to wood wall assemblies.

In addition to the above modification, we are also proposing the deletion of the R-19+6.2 assembly configuration for the Wood 16 O/C category R-20. After a re-analysis we found that the U-factor is higher than the wood assembly U-factor comparison sufficient enough to recommend its departure.

**Conclusion:** Adopting the proposed modifications is intended to provide related prescriptive for cold-formed steel framed assembly options consistent with the options listed for wood framed assemblies in the opaque thermal envelope tables.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This section provides information that was not previously set forth in the code, and does not change the requirements of current code, thus there is no cost impact when compared with present requirements.
2018 International Energy Conservation Code

Delete without substitution:

R402.2.7 Walls with partial structural sheathing. Where Section R402.1.2 requires continuous insulation on exterior walls and structural sheathing covers 40 percent or less of the gross area of all exterior walls, the required continuous insulation R-value shall be permitted to be reduced by an amount necessary, but not more than R-3 to result in a consistent total sheathing thickness on areas of the walls covered by structural sheathing. This reduction shall not apply to the U-factor alternative in Section R402.1.4 and the Total UA alternative in Section R402.1.5.

Reason: The purpose of this code change proposal is to improve efficiency by eliminating an unnecessary prescriptive exception to the wall insulation requirements. The IECC currently allows an exception to the otherwise reasonable wall insulation requirements, which results in decreased energy efficiency in up to 40% of the wall area without any corresponding improvements elsewhere in the building. We do not believe it is appropriate to weaken the code simply because of a design choice made by the builder, even if it is a common construction practice. Given the broad range of trade-off options available through the Total UA path, DOE’s REScheck software, the performance path, and the Energy Rating Index, we believe it is no longer necessary to carve out specific exceptions like this when an energy-neutral trade-off could easily be performed in one of these alternative paths.

Cost Impact: The code change proposal will increase the cost of construction.

Construction costs could be increased for the subset of homes that might have taken advantage of this exception in the prescriptive path because it will require the installation of insulation sufficient to meet the R-value requirement in Table R402.1.2. However, this change will not increase costs for homes built to all other compliance paths in the IECC, since the footnote exception already does not apply to those homes. We believe the elimination of this exception will provide homeowners with the superior energy and cost-savings they expect from a code-compliant home.
2018 International Energy Conservation Code

SECTION R402
BUILDING THERMAL ENVELOPE

Revise as follows:

R402.2.8 (N1102.2.8) **Floors.** Floor framing-cavity insulation shall comply with one of the following:

1. Insulation shall be installed to maintain permanent contact with the underside of the subfloor decking in accordance with manufacturer instructions to maintain required R-value or readily fill the available cavity space.
2. Floor framing cavity insulation shall be permitted to be in contact with the top side of sheathing separating the cavity and the unconditioned space below. Insulation shall extend from the bottom to the top of all perimeter floor framing members and the framing members shall be air sealed.
3. A combination of cavity and continuous insulation shall be installed so that the cavity insulation is

**Exception:** As an alternative, the floor framing-cavity insulation shall be in contact with the top side of sheathing separating the cavity and the continuous insulation that is installed on the bottom side of the floor framing where combined insulation meets or exceeds the minimum wood frame wall R-value in Table R402.1.2 and that extends separating the cavity and the unconditioned space below. The combined R-value of the cavity and continuous insulation shall equal the required R-value for floors. Insulation shall extend from the bottom to the top of all perimeter floor framing members, members and the framing members shall be air sealed.

**Reason:** With the introduction of the exception in this section of the code in the 2015 IECC, it has become exceedingly difficult to not only understand what installations are allowed but how to explain and enforce what is allowed. This revision of the language does not change how insulation in floor systems are currently allowed to be installed but clarifies and simplifies the language. To better understand the requirements, I have included the diagrams below:
Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is not cost impact associated with this proposal as all installations are currently allowed in the IECC.
Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.9 (IRC N1102.2.9) Basement walls. Walls associated with conditioned basements shall be insulated from the top of the basement wall down to 10 feet (3048 mm) below grade or to the basement floor, whichever is less. Walls associated with unconditioned basements shall comply with this requirement except where the floor overhead is insulated in accordance with Sections R402.1.2 and R402.2.8. Comply with the following requirements:

1. Basement walls that define the building thermal envelope shall be insulated. The R-value shall be in accordance with the compliance path that is defined at the time of obtaining the building permit. Unconditioned basements shall comply with the floor insulation requirements of Section R402.2.8.

2. Unfinished basement walls that define the building thermal envelope shall have insulation that is permanently fastened to the wall. The insulation shall cover the exposed portion of the top of the foundation wall not covered by the sill plate, and extend downward to the finished floor below.

3. Finished basement walls that define the building thermal envelope shall be insulated with material that fully fills the framed stud cavity of the finished wall or material that upon installation fully fills the available space. A 1 in. (25 mm) gap is allowed between the framed cavity and insulation, and the concrete foundation wall. Insulation shall be installed between framed bottom plates and the foundation floor when floating walls are used. Insulation shall be installed at the top of the foundation wall not covered by the sill plate.

Reason: This section of the code defines required installation requirements of the code that are not defined by manufacturer instructions. Since the section does not define R-value requirements requirement #1 defines that the R-value installed needs to be in accordance with the compliance path that is used. Requirement #2 is specific to installation requirements for unfinished basement walls and requirement #3 is specific to installation requirements for finished basement walls. All requirements ensure that if the basement wall defines the building thermal envelope it is completely insulated and that there are no thermal bypasses allowed in the installation.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

There is no cost impact associated with this code proposal as it only clarifies the existing installation requirements of the code that are not adequately defined in the current section of the code.
2018 International Energy Conservation Code

Revise as follows:

R402.2.9 (IRC N1102.2.9) Basement walls. Walls associated with conditioned basements shall be insulated from the top of the basement wall down to 10 feet (3048 mm) below grade or to the basement floor, whichever is less. Walls associated with unconditioned basements shall comply with this requirement except where:

1. the floor overhead, including the underside stairway stringer leading to the basement, is insulated in accordance with Sections R402.1.2 and applicable provisions of R402.2 and R402.2.8.
2. there are no uninsulated duct, domestic hot water, or hydronic heating surfaces exposed to the basement, and
3. there are no HVAC supply or return diffusers serving the basement, and
4. the walls surrounding the stairway and adjacent to conditioned space are insulated in accordance with Sections R402.1.2 and applicable provisions of R402.2, and
5. the door(s) leading to the basement from conditioned spaces are insulated in accordance with Sections R402.1.2 and applicable provisions of R402.2, and weatherstripped in accordance with Section R402.4, and
6. the building thermal envelope separating the basement from adjacent conditioned spaces complies with Section R402.4.

Reason: It is outrightly false to presume that the simple act of insulating the floor over the basement absolves one from considering the basement an extension of "conditioned space." This proposal offers an outline of the appropriate characteristics that must be present in order to "willfully and knowingly" remove a basement from consideration as an extension of "conditioned space."

Cost Impact: The code change proposal will increase the cost of construction

One has to presume that if the entirety of the country and affected territories were utilizing the provisions of Section R402.2.9 "as written," that the code change proposed would increase the cost of construction. Our belief is that a significant majority of the country enforcing the 2018 IECC has a level of sophistication consistent with the concepts of thermal and pressure boundaries proposed. As such, we believe, the code change proposal will not increase the cost of construction.
RE56-19
IECC: R402.2.9 (IRC N1102.2.9)

Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code
Revise as follows:

R402.2.9 (IRC N1102.2.9) Basement walls. Walls associated with conditioned basements shall be insulated from the top of the basement wall down to 10 feet (3048 mm) below grade or to the basement floor top of footing, whichever is less. Foundation insulation shall be installed in accordance with the manufacturer’s instructions. Walls associated with unconditioned basements shall comply with this requirement except where the floor overhead is insulated in accordance with Sections R402.1.2 and R402.2.8.

Reason: The language in the IECC requirement is revised by replacing the phrase “or to the basement floor” with “or to the top of the footing.” The top of the footing is lower than the basement floor. This modification is necessary because the foundation system must be protected from heat loss beyond the top of the basement floor system. By providing insulation to the top of the footing, heat loss at the intersection of the concrete floor and the foundation wall is reduced. This heat loss can create durability and moisture issues at the Foundation wall which will encourage mold growth. The section is further amended by adding a sentence that states, “Foundation insulation shall be installed according to the manufacturer’s installation instructions.” This additional requirement is necessary because if the manufacturer’s instructions are not followed, the product may not perform as it is intended.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The code (Section R303.2) currently requires products to be installed in accordance with the manufacturer’s instructions. The proposal simply reinforces the requirement to ensure that the insulation performs as intended. As such, no additional materials or installation labor are necessary.

Proposal # 5129

RE56-19
RE57-19
IECC: R402.4.1.1 (IRC N1102.4.1.1)

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code
Revise as follows:

R402.4.1.1 (IRC N1102.4.1.1) Installation. The components of the building thermal envelope as indicated in Table R402.4.1.1 shall be installed in accordance with Grade I as defined by RESNET/ICC 301 Appendix A, the manufacturer’s instructions and the criteria indicated in Table R402.4.1.1, as applicable to the method of construction. Where required by the code official, an approved third party shall inspect all components and verify compliance.

Reason: Unlike the ERI path, the Prescriptive and Performance path assume that envelope insulation is always installed as intended. Pointing only to the manufacturer’s instructions however makes this very hard to manage for contractors and code officials as there is no central repository of manufacturer’s instructions for them to easily reference nor do they usually have time to read more than what is clearly and simply stated in the Code. Supplementing the manufacturer’s installation instructions with something that is easy for all involved to reference and developed for ICC 700 (an ANSI approved standard that many of the insulation manufacturer’s contributed to) would greatly increase the ease of use of the Code. Usable and understandable Code would lead to better installations and enforcement. The end result then would not be predicted savings (as models already assumes a near perfection which is rarely achieved in real life) but actual energy savings to the end user, i.e. the home owner or apartment dweller.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
If the manufacturer’s instructions are already being met, then this code proposal will not increase or decrease the cost of construction.
**Proponent:** Shauna Mozingo, City of Westminster, representing Colorado Chapter of ICC Energy Code Development Committee (smozingo@cityofwestminster.us)

### 2018 International Energy Conservation Code

**Revises as follows:**

#### TABLE R402.4.1.1 (IRC N1102.4.1.1)

**AIR BARRIER AND INSULATION INSTALLATION**

<table>
<thead>
<tr>
<th>COMPONENT</th>
<th>AIR BARRIER CRITERIA</th>
<th>INSULATION INSTALLATION CRITERIA</th>
</tr>
</thead>
<tbody>
<tr>
<td>General requirements</td>
<td>A continuous air barrier shall be installed in the building envelope. The exterior thermal envelope contains a continuous air barrier. Breaks or joints in the air barrier shall be sealed.</td>
<td>Air-permeable insulation shall not be used as a sealing material.</td>
</tr>
<tr>
<td>Ceiling/attic</td>
<td>The air barrier in any dropped ceiling or soffit shall be aligned with the insulation and any gaps in the air barrier shall be sealed. Access openings, drop down stairs or knee wall doors to unconditioned attic spaces shall be sealed.</td>
<td>The insulation in any dropped ceiling/soffit shall be aligned with the air barrier.</td>
</tr>
<tr>
<td>Walls</td>
<td>The junction of the foundation and sill plate shall be sealed. The junction of the top plate and the top of exterior walls shall be sealed. Knee walls shall be sealed.</td>
<td>Cavities within corners and headers of framewalls shall be insulated by completely filling the cavity with a material having a thermal resistance, R-value, of not less than R-3 per inch. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier.</td>
</tr>
<tr>
<td>Windows, skylights and doors</td>
<td>The space between framing and skylights, and the jamb of windows and doors, shall be sealed.</td>
<td></td>
</tr>
<tr>
<td>Rim joists</td>
<td>Rim joists shall include the air barrier.</td>
<td>Rim joists shall be insulated.</td>
</tr>
<tr>
<td>Floors, including cantilevered floors and floors above garages</td>
<td>The air barrier shall be installed at any exposed edge of insulation.</td>
<td>Floor framing cavity insulation shall be installed to maintain permanent contact with the underside of subfloor decking. Alternatively, floor framing cavity insulation shall be in contact with the top side of sheathing, or continuous insulation installed on the underside of floor framing; and shall extend from the bottom to the top of all perimeter floor framing members.</td>
</tr>
<tr>
<td>Crawl space walls</td>
<td>Exposed earth in unventilated crawl spaces shall be covered with a Class I vapor retarder with overlapping joints taped.</td>
<td>Crawl space insulation, where provided instead of floor insulation, shall be permanently attached to the walls.</td>
</tr>
<tr>
<td>Shafts, penetrations</td>
<td>Duct shafts, utility penetrations, and flue shaft openings to exterior or unconditioned space shall be sealed.</td>
<td></td>
</tr>
<tr>
<td>Narrow cavities</td>
<td></td>
<td>Batts to be installed in narrow cavities shall be cut to fit or narrow cavities shall be filled with insulation that on installation readily conforms to the available cavity space.</td>
</tr>
<tr>
<td>Garage separation</td>
<td>Air sealing shall be provided between the garage and conditioned spaces.</td>
<td></td>
</tr>
<tr>
<td>Recessed lighting</td>
<td>Recessed light fixtures installed in the building shall be sealed to the finished surface.</td>
<td>Recessed light fixtures installed in the building thermal envelope shall be air tight and IC rated.</td>
</tr>
<tr>
<td>Plumbing and wiring</td>
<td></td>
<td>In exterior walls, batt insulation shall be cut neatly to fit around wiring and plumbing, or insulation, that on installation readily conforms to available space, shall extend behind piping and wiring.</td>
</tr>
<tr>
<td>Description</td>
<td>Requirement</td>
<td>Reason</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Shower/tub on exterior wall</td>
<td>The air barrier installed at exterior walls adjacent to showers and tubs shall separate the wall from the shower or tub.</td>
<td>The redundancy in this requirement for continuous air barrier makes this section confusing. The thermal envelope is already the exterior wall so it doesn't make sense to have that verbiage inserted here, so we are removing it along with the redundant statement.</td>
</tr>
<tr>
<td>Exterior walls adjacent to showers and tubs shall be insulated.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Electrical/phone box on exterior walls</td>
<td>The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.</td>
<td></td>
</tr>
<tr>
<td>HVAC register boots</td>
<td>HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.</td>
<td></td>
</tr>
<tr>
<td>Concealed sprinklers</td>
<td>Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.</td>
<td></td>
</tr>
<tr>
<td>a. Inspection of log walls shall be in accordance with the provisions of ICC 400.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reason**: The redundancy in this requirement for continuous air barrier makes this section confusing. The thermal envelope is already the exterior wall so it doesn't make sense to have that verbiage inserted here, so we are removing it along with the redundant statement.

**Cost Impact**: The code change proposal will not increase or decrease the cost of construction

We are just removing redundant language.

Proposal # 5318

RE58-19
2018 International Energy Conservation Code

Add new text as follows:

**R402.2.9 (IRC N1102.2.9) Basement Walls** Basement walls shall be insulated in accordance with Table R402.1.2.

*Exception:* Basement walls associated with unconditioned basements where the floor overhead is insulated in accordance with Sections R402.1.2 and R402.2.8.

Revise as follows:

**R402.2.9 (IRC N1102.2.9) R402.2.9.1 (IRC N1102.2.9.1) Basement walls insulation installation (Mandatory).** Where basement walls are insulated, the insulation shall be installed from the top of the basement wall down to 10 feet (3048 mm) below grade or to the basement floor, whichever is less. Walls associated with unconditioned basements shall comply with this requirement except where the floor overhead is insulated in accordance with Sections R402.1.2 and R402.2.8.

*Reason:* R402.2.9 includes both prescriptive provisions (required insulation levels) and non-tradeable (mandatory) installation specifications. This proposal does not add new requirements; rather, it separates the prescriptive and mandatory provisions into separate sections.

The insulation installation requirements of new Sec. R402.2.9.1 have no value or metric that can be used for modeling purposes; they are non-tradeable (mandatory).

Note that the SEHPCAC has a proposal to eliminate the use of the labels "prescriptive" and "mandatory" in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful, ICC staff have stated that sections being individually approved to be labeled as 'mandatory' will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will increase the cost of construction

The code change may increase construction costs for a subset of buildings that may have been designed using the Total Building Performance or EIR compliance methods that did not follow the basement wall insulation installations provisions contained in this section.
Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.10 (IRC N1102.2.10) Slab-on-grade floors. Slab-on-grade floors with a floor surface less than 12 inches (305 mm) below grade shall be insulated in accordance with Table R402.1.2. The insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall. Insulation located below grade shall be extended the distance provided in Table R402.1.2 by any combination of vertical insulation, insulation extending under the slab or insulation extending out from the building. Insulation extending away from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall.

Exception: Slab-edge insulation is not required in jurisdictions designated by the code official as having a very heavy termite infestation.

Add new text as follows:

R402.2.10.1 (IRC N1102.2.10.1) Slab-on-grade floor insulation installation (Mandatory) Where installed, the insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall. Insulation located below grade shall be extended the distance provided in Table R402.1.2 by any combination of vertical insulation, insulation extending under the slab or insulation extending out from the building. Insulation extending away from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall.

Reason: R402.2.10 includes both prescriptive provisions (insulation levels) and non-tradeable (mandatory) installation specifications, plus an embedded exception for termite infestations.

This proposal does not add new requirements; rather, it separates the prescriptive and mandatory provisions into separate sections and clarifies the exception to required insulation in jurisdictions designated by the code official as having a very heavy termite infestation.

The insulation installation requirements of new Sec. R402.2.10.1 have no value or metric that can be used for modeling purposes; they are non-tradeable (mandatory).

Note that the SEHPCAC has a proposal to eliminate the use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful, ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will increase the cost of construction

The code change may increase construction costs for a subset of buildings that may have been designed using the Total Building Performance or EIR compliance methods that included slab on grade with insulation installed not in accordance with the provisions of this section.
IECC: R402.2.11 (IRC N1102.2.11)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robbys@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

R402.2.11 (IRC N1102.2.11) Crawl space walls. As an alternative to insulating floors over crawl spaces, crawl space walls shall be insulated provided that the crawl space is not vented to the outdoors. Crawl space wall insulation shall be permanently fastened to the wall and shall extend downward from the floor to the finished grade elevation and then vertically or horizontally for not less than an additional 24 inches (610 mm), sill plate on top of the crawlspace wall to the floor of the crawlspace. Exposed earth in unvented crawl space foundations shall be covered with a continuous Class I vapor retarder in accordance with the International Building Code or International Residential Code, as applicable. Joints of the vapor retarder shall overlap by 6 inches (153 mm) and be sealed or taped. The edges of the vapor retarder shall extend not less than 6 inches (153 mm) up stem walls and shall be attached and sealed to the stem walls.

Reason: The foundation of an unvented conditioned crawlspace must be insulated to have a continuous building thermal envelope. It is less clear if the floor of the crawlspace needs to be insulated. However, what is known is that the extension of the wall insulation 24” horizontally over the dirt or vapor retarder on the dirt floor inside the crawlspace is not being enforced with any regularity. When using the Ekotrope or REMRate modeling software to demonstrate compliance with the cost compliance report used in Section R405 it is easy to demonstrate no value associated with the 24” of extended insulation. The crawlspace dirt floor is 3-5 feet below grade and it is not required to be insulated fully. Similarly, there is no requirement to insulate the concrete floor in a basement that is eight feet below grade. If there were a requirement there would be countless arguments regarding the cost-effectiveness of the insulation. This proposal aims to take the 24” extension of insulation out of the code in order to fully focus on insulating the portion of the foundation that is associated with the majority of the heat loss or gain.

On the other side of the equation, when portions of concrete foundation walls are not insulated such as the top of the foundation adjacent to the sill plate it is easy to demonstrate value for the installation of insulation. IR camera imaging, as well as Ekotrope and REMRate modeling, can demonstrate the impact of small portions of uninsulated building thermal envelope.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Would be cost saving associated with this proposal as the 24” extension of insulation over the floor of the crawlspace would be removed as a requirement from the code while asking for a small portion of insulation to be installed at the top of the foundation wall.
2018 International Energy Conservation Code

Add new text as follows:

R402.2.11 (IRC N1102.2.11) Crawl space walls. Crawl space walls shall be insulated in accordance with Table R402.1.2.

Exception: Crawlspace walls associated with a crawlspace that is vented to the outdoors and the floor overhead is insulated in accordance with Sections R402.1.2 and R402.2.8.

Revise as follows:

R402.2.11 (IRC N1102.2.11) R402.2.11.1 (IRC N1102.2.11.1) Crawl space walls, walls insulation installation (Mandatory). As an alternative to insulating floors over crawl spaces, crawl space walls shall be insulated provided that the crawl space is not vented to the outdoors. Where crawl space wall insulation is installed, it shall be permanently fastened to the wall and shall extend downward from the floor to the finished grade elevation and then vertically or horizontally for not less than an additional 24 inches (610 mm). Exposed earth in unvented crawl space foundations shall be covered with a continuous Class I vapor retarder in accordance with the International Building Code or International Residential Code, as applicable. Joints of the vapor retarder shall overlap by 6 inches (153 mm) and be sealed or taped. The edges of the vapor retarder shall extend not less than 6 inches (153 mm) up stem walls and shall be attached to the stem walls.

Reason: Originally drafted as one section, the language included both prescriptive provisions (insulation levels) and mandatory insulation installation, and an embedded exception. This proposal does not add new requirements, it separates the prescriptive and mandatory provisions as well as the exception.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The code change may increase construction costs for a subset of buildings that may have been designed using the Total Building Performance or EIR compliance methods that included slab on grade with insulation installed not in accordance with the provisions of this section.
RE63-19
IECC: R402.2.14 (IRC N1102.2.14) (New)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association (jwoestman@kellencompany.com)

2018 International Energy Conservation Code
Add new text as follows:

R402.2.14 (IRC N1102.2.14) Airspaces. Where the thermal properties of airspaces are used to comply with this code in accordance with Section R401.2, such airspaces shall be enclosed in an unventilated cavity constructed to minimize air-flow into and out of the enclosed air space. Airflow shall be deemed minimized when the enclosed airspace is located on the interior side of the continuous air-barrier and is bounded on all sides by building components.

Exception: The thermal resistance of airspaces located on the exterior side of the continuous air barrier and adjacent to and behind the exterior wall-covering material shall be determined in accordance with ASTM C1363 modified with an airflow entering the bottom and exiting the top of the airspace at an air movement rate of not less than 70 mm/second.

Reason: This proposal is identical to requirements for airspaces added to the 2018 IECC-C (Section 402.2.7). It also is consistent with ASHRAE 90.1-2016 (Section A9.4.2) which was the basis for IECC-C Section 402.2.7. These provisions will ensure that the R-value of airspaces are properly accounted for when used as an optional means of energy code compliance.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The proposal provides needed requirements for the additional and optional use of airspaces as a supplemental means of energy code compliance. This proposal may add an option that's currently not in the code.
2018 International Energy Conservation Code

Add new text as follows:

R402.2.14 (IRC N1102.2.14) Airspaces Where the R-value of an airspace is used for compliance in accordance with Section R401.2, the airspace shall be located on the interior side of the continuous air barrier and bounded on all sides by building components.

Exception: Alternative airspace conditions and means of determining R-value shall be permitted in accordance with Section C402.2.7.

Reason: This proposal coordinates the residential provisions with the prescriptive “deemed-to-comply” requirements for airspaces added to the 2018 IECC-C (Section 402.2.7). These requirements also are consistent with and based on ASHRAE 90.1-2016 (Section A9.4.2). They are applicable to both commercial and residential buildings because the thermal behavior of airspaces in assemblies doesn’t depend on building occupancy or use. Therefore, it is appropriate to consistently address airspace requirements in the IECC-R when their thermal resistance (R-value) is used as a means for compliance through the prescriptive, performance, or ERI approach of Section R401.2. An exception is provided to give flexibility for alternative airspace configurations or solutions based on the provisions (and exception) in Section C402.2.7 of the IECC-Commercial provisions.

For background on why these provisions were added to the 2018 IECC-C and also are needed in the IECC-R, the following explanation is provided. The R-values of airspaces are based on an assumption of “no air leakage” (see 2013 ASHRAE Handbook of Fundamentals, Chapter 26, Table 3, footnote b). This is illustrated in the figure below as an “ideal airspace”. As a practical matter, however, fully enclosed airspaces located to the interior of an air barrier are permitted to be considered ideal (see Case 1 in figure below). But, many airspace applications are far from “ideal” and are not fully enclosed; see Case 2 in the figure below. Air leakage into and out of an air-space due to ventilation airflow (especially if an intentionally vented airspace as common behind cladding systems) can significantly degrade its R-value, yet there is currently no standard calculation method or test method to account for this impact on an airspace R-value that otherwise is assumed to be “ideal”. This concern has been appropriately addressed in the IECC-C and, therefore, should be consistently applied to the IECC-R.

For additional information regarding performance of different air-space applications and conditions that affect R-value performance, refer to the figure below, a powerpoint at http://www.appliedbuildingtech.com/content/air-space-r-value, and the research report referenced in the bibliography.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The use of airspaces for compliance is not a requirement in the code and is therefore optional. This proposal provides for the option to appropriately include the R-value of airspaces which may reduce the cost of construction. For current applications that are using the R-value of airspaces that are not appropriately quantified or constructed, the cost of construction may increase. Thus, the appropriate conclusion is that the proposal may reduce cost, increase cost, or have no impact on cost depending on the specific case.
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

RADIANT BARRIER. A material having a low emittance surface of 0.1 or less installed in building assemblies.

Add new text as follows:

R402.3 (IRC N1102.3) Radiant barriers (Mandatory). Where installed to reduce thermal radiation, radiant barriers shall be installed in accordance with ASTM C1743.

Add new standard(s) as follows:

ASTM C1743: Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction

Reason: This proposal DOES NOT require the use of radiant barriers. But rather requires that WHEN radiant barriers are used, they comply with the appropriate ASTM standard. Furthermore this proposal provides important information to the code user and code enforcement community regarding radiant barriers.

The definition for "Radiant Barrier" was approved in the last cycle and is included in the 2015 IBC.

The proposed language is being included in this section specifically because the American Society for Testing and Materials (ASTM) classifies radiant barriers as thermal insulation. The ASTM committee C16 on Thermal Insulation includes published standards for this product. Subcommittee C16.21 deals specifically with reflective products, which include reflective insulation, radiant barrier and interior radiation control coatings. C16.21 develops standards and practices for these reflective building material thermal insulating products.

The Federal Trade Commission includes radiant barrier products in “CFR Part 460 Labeling and Advertising of Home Insulation: Trade Regulation Rule”.

Radiant barrier products include a surface with an emittance of 0.1 or less that is installed in roof assemblies or attics with the low-emittance surface facing an open or ventilated air space. The low emittance material can be bonded to plastic film, woven fabric, reinforced paper, OSB or plywood. The thermal performance of radiant barriers depends on emittance and location in the attic, wall or roof assembly. Radiant barriers are predominantly installed in attic spaces below the roof deck. The low-emittance surface of radiant barrier products dramatically reduces the heat gain by radiation into the structure and attic HVAC ducts. For this reason, radiant barriers are especially effective in warm sunny climates where they provide reduced use of air conditioning. Radiant barrier products that are available include single-sheet material, multi-layer assemblies and wood sheathing with attached aluminum film or foil. The single sheet material is installed in roof assemblies by attaching directly to the roof deck, in between the rafters or trusses or to the underside of the rafters or trusses. The foil-faced sheathing is installed with the low-emittance side of the sheathing or panel facing toward the attic space to create a radiant barrier. Attic radiant barriers are in extensive use. These products have been on the market for several decades and are used by 87 of the top 100 US Builders. They have an established history and have been accepted into several regional code requirements. Over one billion square feet of the product is being installed annually.

Many state and jurisdictional codes already include references on radiant barriers. These are the state and city codes that include radiant barrier:

IBC: 2018 Section 1509 Radiant Barriers Installed Above Deck

Hawaii
Chapter 181 of Title 3, 2015, Section 407.2, Table 407.1

Texas

The Code of the City of Austin, Texas, Supplement 134-2018, Chapter 25-12, Article 12, Section R402.6

Florida

Section 405.7.1 Installation Criteria for homes claiming the radiant barrier option

Figure R405.7.1 Acceptable attic radiant barrier configurations

Table R303.2.1 Insulation Installation Standards

California

Title 24, 2016, Part 6, Subchapter 1, Definition Radiant Barrier

Title 24, 2016, Part 6, Subchapter 2, Section 110.8 Mandatory requirements for insulation, roofing products, and radiant barriers

Title 24, 2016, Part 6, Subchapter 8, Section 150.1 (c), Prescriptive standards / component packages

Title 24, 2016, Reference Residential Appendices, Radiant Barriers

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

This proposal will not increase the cost of construction because it only adds informational language regarding radiant barriers.
**2018 International Energy Conservation Code**

Revised as follows:

<table>
<thead>
<tr>
<th>COMPONENT</th>
<th>AIR BARRIER CRITERIA</th>
<th>INSULATION INSTALLATION CRITERIA</th>
</tr>
</thead>
<tbody>
<tr>
<td>General requirements</td>
<td>A continuous air barrier shall be installed in the building envelope. The exterior thermal envelope contains a continuous air barrier. Breaks or joints in the air barrier shall be sealed.</td>
<td>Air-permeable insulation shall not be used as a sealing material.</td>
</tr>
<tr>
<td>Ceiling/attic</td>
<td>The air barrier in any dropped ceiling or soffit shall be aligned with the insulation and any gaps in the air barrier shall be air sealed. Access openings, drop down stairs or knee wall doorsto unconditioned attic spaces shall be air sealed in a manner that does not interfere with its accessibility.</td>
<td>The insulation in any dropped ceiling/soffit shall be aligned with the air barrier. All access hatches and doors shall be installed in accordance with Section R402.2.4 Raised vertical or diagonal surfaces that are greater than 1’ foot in height into the ventilated attic shall be insulated in accordance with the knee wall provisions. Raised vertical or diagonal surfaces that are 1 foot or less in height into a ventilated attic shall be buried with insulation to maintain the ceilings R-value. Eave Baffles shall be installed in accordance with Section R402.2.3</td>
</tr>
<tr>
<td>Walls</td>
<td>The junction of the foundation and sill plate shall be sealed. The junction of the top plate and the top of exterior walls shall be sealed. Knee walls shall be sealed. Cavities within corners and headers of framed walls shall be insulated by completely filling the cavity with a material having a thermal resistance, R-value, of not less than R-3 per inch. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier.</td>
<td>—</td>
</tr>
<tr>
<td>Windows, skylights and doors</td>
<td>The space between framing and skylights, and the jambs of windows and doors, shall be sealed.</td>
<td>—</td>

<td>The air barrier installed at exterior walls adjacent to showers and tubs shall separate the wall from the shower or tub.</td>
<td>Exterior walls adjacent to showers and tubs shall be insulated.</td>
</tr>
<tr>
<td><strong>Electrical/phone box on exterior walls</strong></td>
<td>The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.</td>
<td>—</td>
</tr>
<tr>
<td><strong>HVAC register boots</strong></td>
<td>HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.</td>
<td>—</td>
</tr>
<tr>
<td><strong>Concealed sprinklers</strong></td>
<td>Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.</td>
<td>—</td>
</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Air barrier and air sealing criteria section:
- Air sealing measures are called out so the table column should incorporate air sealing in its name as it is different than air barrier.
- We are seeing attic access hatches caulked shut so the included language change is to ensure that access to the attic space is maintained.

**Insulation installation criteria section:**
- Section references have been incorporated in the proposed language change as code required installation issues have been defined in those sections of the code. The problem from an implementation perspective is that the defined installation is in the prescriptive section of the code. So, does the code intend for attic eave baffles to be traded off or not installed if a home uses R405 or R406 compliance paths? I don’t believe so. Therefore, the inclusion of section references ensures enforcement language and that the section becomes mandatory for all pathways in the code as it should be.
- Raised ceiling that penetrate into the attic space are particularly difficult to insulate. The guidance given by the proposed language helps those in the field identify particularly difficult areas to insulate, as well as, guidance on how to successful meet the code requirement.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

**Reason:** Air barrier and air sealing criteria section:

- This code change proposal is intended to offer clarification to this section of table R402.4.1.1 for those in the field that use it to build homes that are compliant with the air testing requirements of the IECC. In the 2018 IECC definitions section, air barriers and building thermal envelope where changed to recognize that the air barrier and building thermal envelope are an assembly of things not necessarily one component of the building. See definitions below. By removing poor language regarding continuous air barriers this section has been focused to better define the alignment of the air barrier and thermal barrier. In addition, it offers definition for other requirements in the table for installing an interior air barrier in location like behind a tub.
  - **AIR BARRIER.** One or more materials joined together in a continuous manner to restrict or prevent the passage of air through the building thermal envelope and its assemblies.
  - **BUILDING THERMAL ENVELOPE.** The basement walls, exterior walls, floors, ceiling, roofs and any other building element assemblies that enclose conditioned space or provide a boundary between conditioned space and exempt or unconditioned space.
  - Air sealing measures are called out so the table column should incorporate air sealing in its name as it is different than air barrier.

**Insulation Installation Criteria:**

- Manufacturers of air permeable insulation have begun to recognize that their installation literature must incorporate language and pictures showing that air permeable insulation must be enclosed inside of air barrier assemblies. This table promotes this installation instruction in location such as behind tubs, on attic knee walls, etc. Therefore, the general section should begin with an overarching statement that states how air permeable insulation shall be installed.
  - See attached PDF insulation installation instructions from NAIMA

**A footnote** has been added to ensure a common understanding that insulation installed in a ventilated attic and at the rim joist is not required to be enclosed within an air barrier assembly. The new footnote is necessary as the item it is associated with defines the installed alignment between air barriers and air permeable insulation within building cavity installation, i.e. walls and floor cavities.

Using references to other sections of the code enables reinforcement of what is required. In this case, the reference is to certificates that document the R-values of the material installed which must be created and posted.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

</table>

---

### Reason

**Component:**
- The component section of this table item has been amended to include other obstructions as there are a number of obstructions that end up in insulated building cavities that insulation must be split around so that it fully encloses the obstruction. In this revised section plumbing and wiring become examples of obstructions, but things like gas or HVAC duct works amongst other things now can be included.

### Air Barrier and Air Sealing Criteria Section

- Although it seems obvious it does need to be stated that holes in the continuous air barrier need to be sealed. This is a specific reminder regarding holes that are created by wiring, plumbing, or other obstruction in cavities need to be air sealed.

### Insulation Installation Criteria

- Insulating around obstructions in building cavities can and may happen with material other than fiberglass batts. This code change proposal opens up the possibility of insulating plumbing in exterior walls, for example, so that the plumbing is not surrounded by insulation but rather completely exposed to the warm side of the cavity.

### Cost Impact

The code change proposal will not increase or decrease the cost of construction. The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements.

---

Proposed # 5396

---

**Reason:**

Component:
- Inspection of log walls shall be in accordance with the provisions of ICC 400.

Plumbing and wiring
In exterior walls, batt insulation shall be cut neatly to fit around wiring and plumbing, or insulation that on installation readily conforms to available space, shall extend behind piping and wiring.

Shower/tub on exterior wall
The air barrier installed at exterior walls adjacent to showers and tubs shall separate the wall from the shower or tub. Exterior walls adjacent to showers and tubs shall be insulated.

Electrical/phone box on exterior walls
The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.

HVAC register boots
HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.

Concealed sprinklers
Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesive sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

---

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Add new text as follows:

**TABLE R402.2.4.1.1(2) [IRC N1102.2.4.1.1(2)]**

<table>
<thead>
<tr>
<th>Grade 1 Insulation Installation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inspection is conducted before insulation is covered.</td>
</tr>
<tr>
<td>Air-permeable insulation is enclosed on all six sides and is in substantial contact with the sheathing material on one or more sides (interior or exterior) of the cavity. Air permeable insulation in ceilings is not required to be enclosed when the insulation is installed in substantial contact with the surfaces it is intended to insulate.</td>
</tr>
<tr>
<td>Cavity insulation uniformly fills each cavity side-to-side and top-to-bottom, without substantial gaps or voids around obstructions (such as blocking or bridging).</td>
</tr>
<tr>
<td>Cavity insulation compression or incomplete fill amounts to 2 percent or less, presuming the compressed or incomplete areas are a minimum of 70 percent of the intended fill thickness; occasional small gaps are acceptable.</td>
</tr>
<tr>
<td>Exterior rigid insulation has substantial contact with the structural framing members or sheathing materials and is tightly fitted at joints.</td>
</tr>
<tr>
<td>Cavity insulation is split, installed, and/or fitted tightly around wiring and other services.</td>
</tr>
<tr>
<td>Exterior sheathing is not visible from the interior through gaps in the cavity insulation.</td>
</tr>
<tr>
<td>Faced batt insulation is permitted to have side-stapled tabs, provided the tabs are stapled neatly with no buckling, and provided the batt is compressed only at the edges of each cavity, to the depth of the tab itself.</td>
</tr>
<tr>
<td>Where properly installed, ICFs, SIPs, and other wall systems that provide integral insulation are deemed in compliance with this section.</td>
</tr>
</tbody>
</table>

**Reason:** The table above is copied directly from ICC 700-2015.

Unlike the ERI path, the Prescriptive and Performance path assume that envelope insulation is always installed as intended. Pointing only to the manufacturer's instructions however makes this very hard to manage for contractors and code officials as there is no central repository of manufacturer's instructions for them to easily reference nor do they usually have time to read more than what is clearly and simply stated in the Code. Supplementing the manufacturer's installation instructions with something that is easy for all involved to reference and developed for ICC 700 (an ANSI approved standard that many of the insulation manufacturer's contributed to) would greatly increase the ease of use of the Code. Usable and understandable Code would lead to better installations and enforcement. The end result then would not be predicted savings (as models already assumes a near perfection which is rarely achieved in real life) but actual energy savings to the end user, i.e. the home owner or apartment dweller.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

If the manufacturer's instructions are already being met, then this code change proposal will not increase or decrease the cost of construction.

<tr>
<td><strong>Concealed sprinklers</strong></td>
<td>Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.</td>
<td></td>
</tr>
</tbody>
</table>

**a.** Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Air barrier and air sealing criteria section:

- Recessed lighting fixture air leakage is outlined in the prescriptive section R402.4.5 and clearly describes that this component shall be air sealed. The instruction are not limited to sealing the recessed light to the finished surface, so referencing the requirements of the prescriptive section makes sense. In addition, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Insulation Installation Criteria:**

- The concept of burring or surrounding building components in insulation was introduced last code development cycle. Metal housing of air tight canned lights are conductive and are now required to be manufactured so that insulation can be in continuous contact with them. At least R-30 attic insulation is required in all climate zones which means that the depth of the insulation is greater than the height of the recessed canned light. This additional language ensure that the insulation will be installed to fully cover the top of the cannot just be in contact with the side of the can.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Insulation Installation Criteria:

- Many in the field that use table R402.4.1.1 use it as a guide to how to meet the requirements of the codes insulation and air leakage sections. Currently the component section for garage separation is blank on the insulation installation column. Unfortunately, many feel that because the section is blank that there is not a requirement to install insulation in the same manner as any other wall or floor component that separated conditioned and unconditioned space. Therefore, there is need to ensure that the installation criteria is used when assessing R402, R405 and R406 compliance. The addition of this language does that.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Air barrier and air sealing criteria section:
- Air sealing of these small cavities that connect to the exterior air barrier assembly need to be filled with something. Typically expanding air sealing foam would be used. This added language is in recognition that all narrow cavities cannot be practically insulated so instead they can be air sealed.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.
2018 International Energy Conservation Code
Revise as follows:

TABLE R402.4.1.1 (IRC N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

<table>
<thead>
<tr>
<th>COMPONENT</th>
<th>AIR BARRIER CRITERIA</th>
<th>INSULATION INSTALLATION CRITERIA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shafts, penetrations</td>
<td>Duct shafts, utility penetrations, and flue shaft openings, and other similar penetrations to the exterior or unconditioned space shall be air sealed.</td>
<td>Penetrations through the building thermal envelope and what is passed through the penetration, shall not damage or compress the insulation surrounding the penetration.</td>
</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Reason: Air barrier and air sealing criteria section:
- There are a number of penetrations that occur through the continuous air barrier assemblies of a home. They are too numerous to list yet some examples are given to create context and additional language was added to ensure that the examples were not thought to be the only penetrations that needs to be sealed.

Insulation Installation Criteria:
- Insulating properly around a penetration and the object that is placed through the penetration in the buildings continuous air barrier assembly and thermal envelop is relatively easy to accomplish when insulation is installed after the penetration has been sealed, but when insulation has been installed first and then a penetration is created damaged insulation often occurs. In either instance this new language points out that insulation still must be installed well regardless.

See attached PDF for pictoral documentation

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

<td>-</td>
</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Component:
- Currently only crawl space walls are being addressed by this table. Other foundation types such as basement and slabs have components that need to be addressed, thus the proposal to change the title of this component section.

**Air barrier and air sealing criteria section:**
- The vapor retarder criteria outlined in the prescriptive section R402.2.11 clearly describes how vapor retarders must be installed over the dirt floor of a conditioned crawl space. There is no need to further explain it in this table, but there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.
- Borrowing from language used in the EnergyStar checklist, I have used this section to ensure that below grade walls are insulated, but do not contain a class 1 vapor retarder that can trap moisture behind them. More vapor permeable materials such as class 2 Kraft faced batts or perforated vinyl or FSK (foil scrim kraft) blankets, as well as, class 3 vapor retarders are allowed. In Colorado we do see class 1 vapor retarders installed in this location and efficiency a building durability issue occur.
- Many feel that concrete foundation walls and slabs are air tight, but we forget that these building assemblies are often penetrated with sump pits, plumbing lines, and the like. These locations must be addressed in order to meet the air leakage requirements of the code.

**Insulation Installation Criteria:**
- Crawl space insulation installation as outlined in the prescriptive section R402.2.11 clearly describes how insulation must be installed on this component. There is no need to further explain it in this table, but there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.
- Basement wall insulation installation is outlined in the prescriptive section R402.2.9 and clearly describes how insulation must be installed on this component. However, basement walls were never included as a component of this table. Therefore, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.
- Likewise slab insulation is outlined in the prescriptive section R402.2.10 and clearly describes how insulation must be installed on this component. However, slab insulation was never included as a component of this table. Therefore, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

<td></td>
</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Component:
- It needs to be clear that the floor cavities that are being addressed by this table are only floors that separate conditioned from unconditioned space. It is surprising how not all understand this.

**Air barrier and air sealing criteria section:**
- Floor cavities are wall cavities laid down, therefore, air permeable insulation installed inside the cavity also needs to be enclosed by the air barrier assembly. As the IECC allows alternative insulation techniques for insulating floors as seen in the exceptions detailed in Section R402.2.8 it become more important to ensure that the rim joist of the insulated floor not only get insulated, but is air tight, because the insulation no longer must be installed adjacent to the subfloor decking. The proposed language change brings this to light for builders and trades that are executing the code requirements.

**Insulation Installation Criteria:**
- The insulation installation criteria outlined in the prescriptive section R402.2.8 clearly describes how insulation in floor systems must be installed. There is no need to further explain it in this table, but there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.

---

HVAC register boots

HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.

---

Concealed sprinklers

Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

---

Rooms containing a fuel burning appliance

Rooms containing a fuel burning appliance shall comply with Section R402.4.4

Rooms containing a fuel burning appliance shall be insulated and air sealed in accordance with Section R402.4.4 and the requirements of this table.

---

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Component Section:
- When added to the IECC, Rooms containing fuels burning appliances defined a new area of the building that defines the separation between conditioned space and unconditioned space (i.e. The Building Thermal Envelope). Therefore, the linkage between the requirements that are listed in the prescriptive section R402.4.4 and table R402.4.1.1 need to be consistently and thoroughly expressed in the code to better ensure compliance.

**Air barrier and air sealing criteria section:**
- Requirements for rooms containing fuel burning appliance is outlined in the prescriptive section R402.4.4 which clearly describes that this room defines the separation between conditioned space and unconditioned space and shall contain air barriers and be air sealed. However, this requirement is located in the prescriptive section of the code and therefore, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Insulation Installation Criteria:**
- Requirements for rooms containing fuel burning appliance is outlined in the prescriptive section R402.4.4 which clearly describes that this room defines the separation between conditioned space and unconditioned space and shall insulated accordingly like any other assembly adjacent to the exterior of the home. However, this requirement is located in the prescriptive section of the code and therefore, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements.

Proposal # 5448

---

RE76-19

---
## AIR BARRIER AND INSULATION INSTALLATION

### General requirements
- A continuous air barrier shall be installed in the building envelope. The exterior thermal envelope contains a continuous air barrier. Breaks or joints in the air barrier shall be sealed.

### Ceiling/attic
- The air barrier in any dropped ceiling or soffit shall be aligned with the insulation and any gaps in the air barrier shall be sealed. Access openings, drop down stairs or knee wall doorsto unconditioned attic spaces shall be sealed.
- The insulation in any dropped ceiling/soffit shall be aligned with the air barrier.

### Walls
- The junction of the foundation and sill plate shall be sealed.
- The insulation in any dropped ceiling/soffit shall be aligned with the air barrier.
- Cavities within corners and headers of framed walls shall be insulated by completely filling the cavity with a material having a thermal resistance, $R$-value, of not less than $R$-3 per inch. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier.

### Windows, skylights and doors
- The space between framing and skylights, and the jambs of windows and doors, shall be sealed.

### Rim joists
- Rim joists shall include the air barrier.

### Floors, including cantilevered floors and floors above garages
- The air barrier shall be installed at any exposed edge of insulation.
- Floor framing cavity insulation shall be installed to maintain permanent contact with the underside of subfloor decking. Alternatively, floor framing cavity insulation shall be in contact with the top side of sheathing, or continuous insulation installed on the underside of floor framing; and shall extend from the bottom to the top of all perimeter floorframing members.

### Crawl space walls
- Exposed earth in unvented crawl spaces shall be covered with a Class I vapor retarder with overlapping joints taped.
- Crawl space insulation, where provided instead of floor insulation, shall be permanently attached to the walls.

### Shafts, penetrations
- Duct shafts, utility penetrations, and flue shaftopening to exterior or unconditioned space shall be sealed.
- Batts to be installed in narrow cavities shall be cut to fit or narrow cavities shall be filled with insulation that on installation readily conforms to the available cavity space.

### Narrow cavities
- Air sealing shall be provided between the garage and conditioned spaces.

### Garage separation
- Air sealing shall be provided between the garage and conditioned spaces.

### Recessed lighting
- Recessed light fixtures installed in the building thermal envelope shall be sealed to the finished surface.
- Recessed light fixtures installed in the building thermal envelope shall be air tight and IC rated.

### Plumbing and wiring
- In exterior walls, batt insulation shall be cut neatly to fit around wiring and plumbing, or insulation, that on installation readily conforms to available space, shall extend behind piping and wiring.

### Shower/tub on exterior wall
- The air barrier installed at exterior walls adjacent to showers and tubs shall separate the wall from the shower or tub.

### Electrical/phone box on exterior walls
- The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.

### HVAC register boots
- HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.
Concealed sprinklers

Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesive sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

Area Separation Walls

Air sealing measures shall be permitted to be installed on top of approved fire blocking material installed within area separation walls when fire blocking remains visible after air sealing, to limit air infiltration and create an air barrier between conditioned and unconditioned space. Area separation/adiabatic walls shall be considered an exterior wall.

Insulation shall fully fill the stud cavity of area separation walls and be installed according to manufacturer instructions. A 1" gap is allowed between the cavity insulation/framing and the area separation wall.

Insulation shall fully fill the stud cavity of area separation walls and be installed according to manufacturer instructions. A 1" gap is allowed between the cavity insulation/framing and the area separation wall.

Insulation shall fully fill the stud cavity of area separation walls and be installed according to manufacturer instructions.

Area Separation Walls

Insulation shall fully fill the stud cavity of area separation walls and be installed according to manufacturer instructions.

A 1" gap is allowed between the cavity insulation/framing and the area separation wall.

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Reason: Component Section:

- The 2009 IECC referenced air sealing common walls between dwelling units and this section of the IECC was removed during the 2012 code development cycle. The removal, however, did not diminish the significance of air leakage within these assemblies either directly from the outside or from unit to attached unit. It is EnergyLogic’s experience that town homes that are twice as small as a single family detached home leak twice as much, or more, than the single family home due solely to the area separation wall. Air sealing of this assembly cannot be ignored if our intent it to provide a code that offers a quantifiable amount of energy savings for all single-family dwelling units. This is why this section is being proposed to be added back into the code within this table.

Air barrier and air sealing criteria section:

- In Colorado we are finding success air sealing on top of approved fire blocking material. In this way the fire UL listed fire blocking material, which is usually installed in the same location where one wants to air seal, is not replaced by a non-UL listed material and the true area separation wall has not been disturbed. Take for example shaft liner area separation wall construction. The fire portion of the assembly is usually tow layers of 1" think type x gypsum which creates a two-hour fire separation. The type x gypsum is also an approved fire block that can be installed between the framing that holds the fire area separation wall in place and the two layers of type x gypsum fire area separation wall. The material is installed in the gap to the ventilated attic, between floors, and to the front and back of the dwelling units. When it is air sealed it is still visible and the air sealing does not impair it fire blocking ability.

- The next proposed language in this section of the table states that area separation walls perform like any other exterior wall so if you have a component of this table that is installed adjacent to an area separation wall then it should be installed in accordance to the requirements and guidance of this table. For example, if a tub, drop ceiling, utility box, or knee wall is installed against an area separation wall then it should be installed in accordance with this table as it is outside of the fire rated portion of the assembly yet is ensures the continuity of the interior air barrier portion of the assembly.

Insulation Installation Criteria:

- The importance of installing insulation in accordance with manufacture instructions within area separation walls cannot be over stated. First, there is a significant amount of ambient air moving within the assemblies so it is a myth to believe that an adiabatic assembly has no heat loss or gain. Second the insulation is also used to dampen sound transmission from unit to unit. For these reasons the insulation installation verification must be equally as stringent as it is when observed in other assemblies. The language in this section specifically deals with the cavity insulation and recognizes that the assembly is often designed with a gap between the insulation and the fire rated portion of the assembly.

</tbody>
</table>

Fire sprinklers installed in locations where they are subject to freezing shall be designed and installed in accordance with Section P2904 or NFPA 13D.

To maintain a contiguous air and thermal barrier it shall be permitted to bury the sprinkler piping in insulation to protect it from freezing.

To determine the minimum amount of insulation required above the sprinkler line when insulation is also installed below the line use the following formulas:

For cold regions: $$R_o = Ri \frac{(To - 40)}{(40 - Ti)}$$

For hot regions: $$R_o = Ri \frac{(To - 120)}{(120 - Ti)}$$

Where:

- $$Ti$$ = ACCA manual J Conditioned living space Indoor heating or cooling design temperature.
- $$To$$ = The lowest/highest recorded temperature of the outdoor, unconditioned attic space.
- $$Ri$$ = The R-value of the insulation used between the tubing and the conditioned living space below.
- $$R_o$$ = The R-value of the insulation used above the tubing.

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Currently no insulation installation guidance is offered by table R402.1.1 from concealed sprinklers and the majority of the time sprinkler lines that are installed within the building's thermal envelop or in ventilated unconditioned attics are installed in such a way that dramatically impacts the energy performance of the sections of envelope they are installed in. This is primarily due to installing insulation only on the cold side of the sprinkler line which creates a miss alignment between the insulation and the air barrier. Installation techniques like tenting over the top of the sprinkler line or placing all the insulation to the cold side of the assembly are not part of the insulation manufactured installation instructions for any other obstruction in the assembly including water lines.

This proposed language and formula come from Uponor who manufactures a potable water fire sprinkler system that at times gets installed outside the conditioned space of the home. There is no sure way to ensure that the sprinkler line will not freeze regardless of how it is installed if the line is run in unconditioned space, but there are options out there to insulate the line and not damage the overall performance of the building's thermal envelope. The proposal language merely points out the option without making any requirements that the insulation must be installed in a particular fashion. It mirrors the air barrier air sealing column of this section in that it does not attempt to supersede any fire code requirement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements.

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Air barrier and air sealing criteria section:
- The change to this section of language in the table slightly broadens the scope of sealing to not only include air sealing between inside and outside but to include sealing of all supply and return boots to the surface they penetrate. This helps to gain more control and predictability of air flow in and out of interstitial spaces as well as improves the performance of the HVAC system. This concept was first introduced by the EnergyStar program.

**Insulation Installation Criteria:**
- Nationally we like open floor plans which means that more and more duct is being installed in exterior walls and attics. The supply and return duct installation and the insulation installation must be coordinated so that the insulation is not damaged or compressed resulting in the reduction of required R-value.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements.

The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.

Electrical, phone, fan or other utility boxes shall be air sealed or air tight boxes shall be installed.

Electrical, phone, fan or other utility boxes, that penetrate the building thermal envelope, shall be air sealed to the subfloor, wall covering or ceiling penetrated by the box.

Spaces behind electrical, phone, fan or other utility boxes on exterior walls shall be insulated or filled by insulation that on installation readily conforms to the available cavity space.

Electrical, phone, fan or other utility boxes installed in floors, attics or to other insulated spaces shall have insulation cut or blown to fit snugly around them or upon installation readily conforms to the available space.

Spaces behind electrical, phone, fan or other utility boxes on exterior walls shall be insulated or filled by insulation that on installation readily conforms to the available cavity space.

HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.

Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives/sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

Proposed # 5441

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Reason: Component column:

- Although technically speaking, low voltage, speaker, or computer wire boxes are a form of electrical box many builders and trade partners only view true 20- or 15-amp power outlet or switch gang boxes as electrical boxes. By simply broadening the definition to utility box we can ensure that any such box that is installed in an exterior wall or ceiling is insulated and air sealed properly.

Air barrier and air sealing criteria section:

- In this section the two requirements have been broken apart for greater clarity. First an air tight box of some sort must be installed and second the box must be sealed to the surface that it penetrates.

Insulation Installation Criteria:

- Currently there is no guidance in this table regarding insulating behind electrical boxes in any insulated assembly. This added language rectifies this and offers guidance.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements

</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Component column:
- The 2012 IECC Air barrier and Insulation table was the last table that specifically referenced the void space behind fireplaces that are located on exterior walls. Just like behind tubs and shower pans, a supplemental air barrier is needed on the interior side to enclose the insulation as the drywall plain has been moved to the front of the fireplace.

**Air barrier and air sealing criteria section:**
- This first revision continues to require the installation of a supplemental air barrier in areas were drywall, tile backer, or other air impermeable material will not be installed as the finished surface is not in alignment with the insulation installed in the building’s thermal envelope. The only addition, other than clarification, is the addition of the area behind fireplaces on exterior walls.
- Air sealing the tub and shower drain trap penetration eliminates a significant leakage source especially when located in floor systems over unconditioned spaces. This air leakage often creates condensation on the back side of tubs and shower pans which leads to mold and other building durability issues.
- Fireplace door air sealing is outlined in the prescriptive section R402.4.2 and clearly describes that this component shall be air sealed. The instruction should not be limited to fireplaces that are installed using the prescriptive compliance options. Therefore, there is need to ensure that the installation criteria is used when assessing R405 and R406 compliance. The addition of this language does that.

**Insulation Installation Criteria:**
- Manufacturers of air permeable insulation have begun to recognize that their installation literature must incorporate language and pictures showing that air permeable insulation must be enclosed inside air barrier assemblies. The current language offered no guidance of this fact and therefore was amended.
- See attached PDF example of newer installation instructions

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposed language does not increase the cost of construction, but rather offers guidance and clarity of existing requirements.

</tbody>
</table>
Plumbing and wiring

In exterior walls, batt insulation shall be cut neatly to fit around wiring and plumbing, or insulation, that on installation readily conforms to available space, shall extend behind piping and wiring.

Shower/tub on exterior wall

The air barrier installed at exterior walls adjacent to showers and tubs shall separate the wall from the shower or tub.

Exterior walls adjacent to showers and tubs shall be insulated.

Electrical/phone box on exterior walls

The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed.

HVAC register boots

HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot.

Concealed sprinklers

Where required to be sealed, concealed fire sprinkler shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.

- Inspection of log walls shall be in accordance with the provisions of ICC 400.
- Air barrier and insulation full enclosure is not required in unconditioned/ventilated attic spaces and at rim joists.

Reason: Table title change

- The objective of table R402.4.1.1 is to offer guidance for how to create an air tight home that meets the air leakage requirements of the IECC. Air barrier and insulation installation are part of the equation to be able to accomplish this goal, but air sealing is another part of it that is missing from the title. The tables name should accurately reflect what it is intended to do and that is what the proposal aim is. Currently air sealing measures are discussed to some extent in the table and the hope is that additional air sealing measure will be incorporated this cycle.

Air barrier and air sealing criteria section:

- In many sections of this table the guidance that is given tells the builder or trade partner to add a supplemental interior air barrier to the assembly. For example, at shafts, double walls, or behind tubs and fireplaces where the interior drywall, or primary interior air barrier is not in alignment with the insulation. The rim joist is one area where a nationally cost-effective solution for enclosing air permeable insulation with an interior air barrier has not been identified. Therefore, it is even more crucial that the exterior air barrier be air tight. The proposed language makes this clear.
- In order for the exterior air barrier to be air tight and air sealed properly the exterior rim board must be sealed to the sill plate and the sub floor. The added language ensure that this crucial area of low side air leakage is addressed.

Insulation installation criteria section:

- A footnote has been added to ensure a common understanding that insulation installed in a ventilated attic and at the rim is not require to be enclosed within an air barrier assembly. The footnote is necessary as the item it is associated with defines the installed alignment between air barriers and air permeable insulation within building cavity installation, i.e. walls and floor cavities.
- Most often fiberglass batt insulation is used to insulate the rim joint area of a home. If the batt is installed so that it is not in contact with the surface it is intended to insulated it does not work properly. We often see it installed in a crescent shape where the bulk of the material is not touching the rim board. The added language and footnote clearly and concisely describe how to insulate this unique area of a home.

See photo examples of the issues in the attached PDF

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.
IECC: TABLE R402.4.1.1

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

TABLE R402.4.1.1 (IRC TABLE N1102.4.1.1)
AIR BARRIER, AIR SEALING, AND INSULATION INSTALLATION

Portions of table not shown remain unchanged.

<tr>
<td>Windows, skylights and doors</td>
<td>The space between framing and skylights, and the jambsof windows and doors, shall be air sealed.</td>
<td>Insulation installed in framing around windows, skylights and doors shall be cut to fit the cavity or shall be filled with insulation that on installation readily conforms to the available cavity space.</td>
</tr>
</tbody>
</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Reason: Air barrier and air sealing criteria section:
- A simple adjective creates better clarity

Insulation installation criteria section:
- Often the framing around windows creates spaces that are odd sizes and shapes. I think of a recent house that I inspected that had several octangle widows fit into a square opening. The cavities that were created would not be defined as narrow cavities section of this table, but would be addressed be the proposed language.

See attached PDF for pictorial documentation of the issue

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

</table>

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** Table title change

- The objective of table R402.4.1.1 is to offer guidance for how to create an air tight home that meets the air leakage requirements of the IECC. Air barrier and insulation installation are part of the equation to be able to accomplish this goal, but air sealing is another part of it that is missing from the title. The tables name should accurately reflect what it is intended to do and that is what the proposal aim is. Currently air sealing measures are discussed to some extent in the table and the hope is that additional air sealing measure will be incorporated this cycle.

**Air barrier and air sealing criteria section:**

- Clarification of the language requiring drywall to be sealed to the top plate is needed. In the field there is confusion regarding what exterior means. Does it mean four exterior walls or does it mean top plates that are adjacent to unconditioned space. The gained clarity of this air sealing activity addresses one of the largest air leakage sources on the high side of the home.
- The junction of the bottom plate to the subfloor on exterior walls had not been addressed yet is again one of the largest sources of air leakage in homes and therefore was added to the table.

**Insulation Installation Criteria:**

- Air permeable insulation must be enclosed in an air barrier in order to trap the pockets of air that are required to resist the flow of energy. This new language expresses that so it can be executed properly in the field.
- Corners and headers are significantly different assemblies. Headers, in particulate may not have a true cavity to insulate and may be better suited to insulate with foam board. This proposal breaks the two assemblies into separately addressed assemblies.
- Adding the defined term Building Thermal Envelope ensures clarity in this section of the code.
- Nationally we are seeing more and more knee walls that are defined by the flat edge of a 2x4 truss. The 1.5” dimension does not offer enough space to properly insulate. In such cases the truss will need to be over framed to enable insulation to be installed. The included language defines the minimum insulated space.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

</tbody>
</table>
Electrical/phone box on exterior walls | The air barrier shall be installed behind electrical and communication boxes. Alternatively, air-sealed boxes shall be installed. | — |
HVAC register boots | HVAC supply and return register boots that penetrate building thermal envelope shall be sealed to the subfloor, wall covering or ceiling penetrated by the boot. | — |
Concealed sprinklers | Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Cauking or other adhesive sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings. | — |

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.
b. The requirements of this table are mandatory in accordance with Section R402.4 and shall be applied to all components of the building’s thermal envelope. Building elements not specifically addressed in the table shall be sealed, as appropriate, and consistent with the requirements of this table in order to maintain the continuity of the air barrier.

**Reason:** The objective of table R402.4.1.1 is to offer guidance for how to create an air tight home that meets the air leakage requirements of the IECC. Air barrier and insulation installation are part of the equation to be able to accomplish this goal, but air sealing is another part of it that is missing from the title. The table name should accurately reflect what it is intended to do and that is what the proposal aims to.

An additional footnote is being proposed here to first reiterate that the items included in this table are mandatory and second to show that in reality the principals demonstrated in the table are the important mandatory items. The code, and this table in particular cannot address every situation that will arise in the field. Therefore, the principals of installation air barrier, air sealing, and insulation installation demonstrated in the table must be clearly expressed and exemplified in order for builders and trade partners to successfully execute them regardless of unique instances of construction and installation occur.

For example, the table reinforces the need for the continuity of the air barrier assembly and its alignment with the thermal barrier of the home. The components described in the table express many of the situations where this must be executed but it can’t explain every unique knee wall, tub, or fire fireplace surround. Therefore, the principals embodied in the table are used to successfully execute the continuity of the air barrier and alignment with insulation throughout the building thermal envelope.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposed language does not increase the cost of construction but rather offers guidance and clarity of existing requirements.

Concealed sprinklers | Where required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesives/sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings. | —  

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

**Reason:** This change gives clarification to utility penetrations sealing of the air barrier and provide for more sustainable sealing and is the same language adopted in the 2018 IECC C402.5.1.1-.

"Penetrations of the air barrier shall be caulked, gasketed or otherwise sealed in a manner compatible with the construction materials and location. Sealing shall allow for expansion and contraction of materials and mechanical vibration."

Sealing need to allow for expansion and contraction of materials so they do not crack, or dislodge form the material they are affixed too. Utility penetrations can be plumbing piping, gas piping but refrigerant piping vibrates and must be sealed in a manner to allow this mechanical vibration.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This change will not increase the cost of construction, the change simply tells the installer that sealing methods must allow for expansion and contraction and in the case of refrigeration piping that unlike other pipe penetration it vibrate so some sealing items might not cope with vibration or turn to power from the friction created

a. Inspection of log walls shall be in accordance with the provisions of ICC 400.

Reason: Currently, the code requires that insulation is installed “in accordance with the manufacturer’s instructions.” As these instructions vary by product and manufacturer, the code requirement for insulation installation quality does not seem to be applied consistently across the industry and is difficult to enforce. The intent of this code change is to establish a single, clear, consistent standard for high-quality insulation installation by leveraging ICC/RESNET 301, a consensus standard already referenced by the 2018 IECC. The intent of the current language is not being realized in the field. A 2016 study of 146 new homes in Massachusetts shows that, despite a long history of utility efficiency programs and progressive energy codes, insulation installation in the state has significant room for improvement. Table 14 of this study provides the full breakdown of insulation installation quality data in these 146 homes; the primary finding is that the vast majority of homes in the state receive merely fair installation quality.

“Auditors estimated that 86% of homes have mostly Grade II, a typical installation quality represented by moderate amounts of gaps and compression. Grade I—the best quality, representing an install with limited installation defects—is the majority install quality in only 10% of the homes.” (pg. 17).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal only provides clearer and more enforceable language than the existing code. It does not alter the intended stringency of the code provision, and it does not incur any additional installation or verification costs. Therefore there is no change in the cost of construction.

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

**DWELLING UNIT ENCLOSURE AREA.** The sum of the area of ceiling, floors, and walls separating a dwelling unit's conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. Wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above.

R402.4 (IRC N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

Revise as follows:

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

**Exception:** An air leakage rate not exceeding 0.30 cfm per ft² of the dwelling unit enclosure area shall be an accepted alternative in all climate zones for:

1. Attached single and multifamily building dwelling units.
2. Buildings or dwelling units that are 1500 square feet or smaller.

R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory). The building and each dwelling unit shall be provided with ventilation that complies with mechanical ventilation. The mechanical ventilation system shall comply with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

**Reason:** Air changes per hour (ACH) is a volumetric calculation that is used to express air exchanges in a home when the house is brought to 50 Pascal's pressure with relation to outside. It is calculated using the house volume and the cubic feet per minute airflow rate as measured at the blower door to reflect the number of times each hour the volume of air in the house is exchanged with the outside. Although it can be used to express the air leakage rate of an efficient or inefficient home, it does not have a direct correlation with the holes through which air is passing and, therefore, is not a measurement that is best used to quantify how air tight a dwelling is. This is especially true for small volume and attached dwellings.

This proposal introduces an exception to using ACH to quantify air leakage in attached and small volume dwelling units because ACH is biased against small volume and attached dwellings. Although it is not difficult to get a single-family median size home to pass 3 or 5 ACH as required by the IECC, it is significantly difficult to get a small volume and an attached home to pass. The alternative metric more accurately reflects leakage through the exterior enclosure area which removes built in volumetric bias while continuing to ensure a tight structure.

The alternative metric uses a cubic foot per minute (CFM) per square foot (ft²) of dwelling unit enclosure area metric to demonstrate compliance with the IECC. This metric allows the air leakage measured at 50 Pascals divided by the building surface area to be used to assess the air tightness of
the building enclosure. Unlike ACH, a CFM/ft² of dwelling unit enclosure area normalizes the building air leakage per unit of building envelope surface area, the actual location where air is infiltrating or exfiltrating the dwelling regardless of where the air is coming from, which removes the volumetric bias that is causing small volume and attached dwellings units to fail the code require blower door test. In addition, it is not possible to only measure air leakage to the ambient outdoors in attached dwellings which is what ACH assumes. The air leakage measurement is actually quantifying the leakage that is coming from attached dwellings, stairs, elevator shafts or other parts of the building that may be connected to the living space of the tested unit. Air leakage from a conditioned space to any other space, as well as, two the ambient outdoors continues to be an energy efficiency issue, but it also is a health issue from an indoor air quality perspective, as well as, a building durability issue from a building science perspective. Reducing air leakage from all surfaces of the building enclosure promotes the IECC’s intent while providing a metric that makes better sense for the building type in question.

The use of a more accurate reflection of air leakage that better represents the distribution of holes that are occurring in the building enclosure has begun to be adopted in programs such as EnergyStar, LEED, and Passive House and by standards created by the US Army Corp of Engineers and ASHRAE. Largey this is happening in multifamily construction as looking at the CFM/ft² of building enclosure area better represents leakage that is occurring in an attached dwelling unit. However, small volume is also a significant issue which this proposal addresses. The CFM/ft² of enclosure area will allow both small volume and attached dwellings to be more successful at meeting the intent and requirements of the code.

Why the change to R403.6?

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to to ensure whole house mechanical ventilation continues to be required and installed

Why The change to IRC 303.4?

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to ensure whole house mechanical ventilation continues to be required and installed.

Cost Impact: The code change proposal will decrease the cost of construction

This proposal would reduce cost for the following reasons:

- Some jurisdictions nationally allow Guarded testing, an alternative blower door testing method that attempts to only quantify air leakage between conditioned space and the outdoors. This testing method requires multiple individuals and blower doors to be run simultaneously. Using a CFM/ft² of enclosure area Metric ensures a tight building thermal enclosure in the most cost-effective way by only requiring one tester and piece of equipment per test.

- Air leakage pathways depend on the type of area separation assembly that is used between attached units. Some assemblies such as shaft liner areas separation walls are fairly tight from unit to unit and leak substantially to the outdoors while others promote leakage between units, common spaces, and other defined unconditioned spaces in the building. An enclosure test for attached dwellings allows for identification of the most cost-effective air sealing option per assembly that is chosen.

- Air sealing of exterior walls in mid to large size single family homes has become cost effective, repeatable, and achievable. Small volume homes don’t have the same opportunities for sealing as volume is the primary driver not the number or size of holes to the exterior. Therefore, multiple re-inspections are needed and additional application of air sealing measures to chase down very small reductions in air leakage that still don’t result in passing 3 and in some cases 5 ACH occur. A more reasonable metric for small volume dwelling would result in more passing units and less re-inspections while still meeting the tightness goals of the code.

- In attached housing there is an additional fire and air separation wall, floor, and or ceiling where often only a limited amount of air sealing is allowed. However, with a reasonable metric such a 0.30 CFM/ft² of enclosure area one is looking at the entire surface area. This creates parity with single family homes when it comes to sealing all surfaces of the dwelling. This testing method requires multiple individuals and blower doors to be run simultaneously. This creates parity with single family homes when they have the opportunity to address all surfaces of the dwelling when seeking to reduce the infiltration rate to pass the requirements of code.

- The value of allowing an exception to use 0.30 CFM/ft² of enclosure area is that air-sealing varies directly with the amount of surface area. Two dwellings can have surface area that differs by 15%, but still have the same volume and the current metric offers the same leakage allowance. If the surface area can be addressed in the measurement than the playing field is leveled and attached small volume dwelling units would not have the problems passing the IECC.
RE89-19
IECC: R402.4.1.2 (IRC N1102.4.1.2)

Proponent: Roger Papineau, Self, representing Self (hbagta.codeguy@gmail.com)

2018 International Energy Conservation Code

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Exception: For additions and alterations, the air barrier and insulation shall be inspected in accordance with TABLE R402.4.1.1.

Reason: Some building officials are refusing to accept reports from certified blower door test providers. This requirement may create for-profit third party companies. Exception. There is no economical prescriptive method of separating the existing structure from the new work. The common wall, or floor/ceiling have no air leakage requirements and therefore could create false ACH results.

Cost Impact: The code change proposal will decrease the cost of construction. This may result in cost savings by eliminating unreliable testing.

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

DWELLING UNIT ENCLOSURE AREA. The sum of the area of ceiling, floors, and walls separating a dwelling unit's conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. Wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above.

Revise as follows:

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour or 0.28 cubic feet per minute (CFM) per square foot (ft²) of dwelling unit enclosure area in Climate Zones 1 and 2, and three air changes per hour or 0.17 CFM per (ft²) of dwelling unit enclosure area in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

R403.6 (IRC N1102.6) Mechanical ventilation (Mandatory). The building and each dwelling unit shall be provided with ventilation that complies with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

Reason: Air changes per hour (ACH) is a volumetric metric that is useful for air quality measurements in buildings but is not the correct expression of air leakage from an energy or building durability perspective. This proposal introduces the ability to use an alternative cubic foot per minute (CFM) per square foot (ft²) of dwelling unit enclosure area metric for measuring air leakage in a building. In this way, the air leakage measured at 50 Pascals divided by the building surface area is used to assess the airtightness of the construction and building envelope. Unlike ACH, a CFM/ ft² of dwelling unit enclosure area metric normalizes the building air leakage per unit of building envelope surface area; the actual location where air is infiltrating or exfiltrating the building. To this end, the proposal also defines “Dwelling Unit Enclosure Area” as the sum of the area of ceiling, floors, and walls separating a dwelling unit's conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. In addition, the definition offers guidance to further understand the measurement that must take place to calculate the dwelling unit enclosure area. This guidance states that the wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above. Lastly, the proposal ensures that the intent of the code, to ensure that the structure is built tight and ventilated correctly with mechanical ventilation, is maintained. If an additional option is adopted into the code, as proposed, then ventilation must also be ensured regardless of how air tightness of the structure is expressed.

Since 1980, The Energy Conservatory, has not only been a leader in air leakage science, but also one of the prominent manufacturers of the blower door air measurement tool. In their article, “Which Is A Better Metric For Measuring Airtightness: ACH @ 50 Pa Or CFM/ Ft² Of Surface Area @ 50 Pa?”, which is adapted and added to in this reason statement, we get the basis of the argument for the introduction of a new metric into the International Energy Conservation Code for the measurement of air leakage.

To paraphrase, when measuring the airtightness of a building the objective is to learn how much leakage is occurring across the building's enclosure area. It is analogous to moisture permeability or the measurement of moisture across the building's enclosure area and thermal transmittance, the rate at which heat is transferred across the building enclosure area. The rate of air leakage or tightness does not depend on the volume of the structure as defined by the building's enclosure area but does depend on the holes associated with the surface area of the structure. Air
permeability of a material is typically measured as the flow per area at a given pressure difference across the material. U value measurements are similar. If we want a metric to use to measure the airtightness quality of construction of the exterior enclosure of buildings it makes sense to use a metric that equates flow to the size and number of holes in the building’s thermal enclosure.

The article continues with an example to help demonstrate how volume is not proportional to surface area:

Comparison between ACH50 and CFM50/ft² for a 2000 ft² home at 3 ACH50

House Is 50 X 40 X 8

Volume = 16,000 ft³

Surface Area = 50 X 40 X 2 + 180 X 8 = 5440 ft²

CFM50 = (3 X 16000)/60 = 800 CFM

CFM50/ft² = 800/5440 = 0.147 CFM50/ft²

Increase height to 2 story at 3 ACH50

House Is 50 X 40 X 16 Volume = 32,000 ft³

Surface area = 50 X 40 X 2 + 180 X 16 = 6880 ft²

CFM50 = (3 X 32000)/60 = 1600 cfm

CFM50/ft² = 1600/6880 = 0.233 CFM50/ft²

In this example, when the volume is doubled, the surface area increased by 26%. And when the ACH50 stays the same, the CFM/ ft² of surface area increased by 58%. I have attached an Excel spreadsheet calculator that further defines the disconnect between ACH and CFM/ ft² of surface area to further elaborate the issue. In the attached calculator you can change the ratio of width and length of the building to see the effect on the resulting expressions of air leakage. An independent yet similar calculator can be found at this Residential Energy Dynamic link http://www.residentialenergydynamics.com/REDCalcFree/Tools/AirLeakageMetrics

The primary purpose of this code change proposal is to introduce the CFM/ft² of surface area metric into the code. Deciding on where to set the minimum allowable leakage rate is difficult largely due to the earlier volume and surface area discussion. Both tests are performed at a pressure differential of 0.2 inch water gauge (50 Pa), which is the traditional residential testing pressure so an attempt was made to align the introduction of a CFM/ft² of surface area metric with the existing ACH50 metric of 3 and 5 air changes per hour. ACH being a volumetric measurement penalized small volume dwelling units so a decision was made to concentrate on a size range of dwellings between 2500 and 5500 square feet. By doing this and using the attached conditioned floor space to shell area calculator we were able to see that little variation occurred between ACH and CFM/ft² of surface area metric when changing the size ratio of the modeled house within this house size range. By rounding up, the proposal is using .17 CFM/ft² of surface area metric to align with 3 ACH and .28 CFM/ft² of surface area metric to align with 5 ACH. By using these numbers, small volume homes, while not having a volumetric penalty, are allowed to be a little more leaky and large volume homes must achieve just about the same level of tightness if not a slight bit more. As the average home size in the United States is approximately just less than 2500 square feet this code change proposals purpose of introducing a better measurement metric without removing the codes traditional measurement methodology, provide additional flexibility while maintaining similar stringency.

The Energy Conservatory suggests that the use of Air Changes per Hour at 50 Pa (ACH50) started approximately 60 years ago by researchers who were interested in ways to predict the natural infiltration rate of buildings, which at the time was most commonly measured in Air Changes per Hour. At the time air quality in buildings was being studied and the metric made sense. If a pollutant is released in a building, the time for the concentration to decay by a certain percentage depends on the infiltration measured in air changes per hour. The analysis of a tracer gas decay test gives a result in air changes per hour. So, when they started measuring airtightness, for use in estimating natural infiltration in air changes per hour, it made sense to use ACH50 as the metric.

However, as discussed earlier, two homes with the same volume can have very different surface areas and holes associated with the building enclosure area.
Value is gained by including a surface area-based metric in that air-sealing varies directly with the amount of surface area not the amount of volume in the dwelling. Two buildings can have surface areas that differ by 15%, but have the same volume and the current metric offers the same leakage allowance. Therefore, if the purpose of measuring air leakage is to determine something about the construction quality, air leakage rate, energy efficiency and building durability the metric should be associated with the flow of air through holes in the enclosure. To quantify these things ACH is the wrong metric. It does not tell you anything about the quantity and air leakage through holes in the building. Conversely, the CFM/ft² of surface area metric concretely expresses the quantity of air leakage through the building’s exterior enclosure. When an enclosure is tight more energy is conserved as well as allowing better control and predictability of air flow, thermal flow, and moisture flow.

Many standards are now using square foot of enclosure area instead of ACH. Examples include EnergyStar, US Army Corp of Engineers, LEED, US Passive House and ASHRAE 62.2. This proposal is the first step to bring this better expression of air leakage into the code. It has been created in such a way that options are maintained allowing jurisdictions and building professionals flexibility in defining air leakage requirements.

Link to Energy Conservatory article from which portions of this reason statement have been added:

https://support.energyconservatory.com/hc/en-us/articles/204176240-Which-is-a-better-metric-for-measuring-airtightness-ACH-50-Pa-or-CFM-ft-of-surface-area-50-Pa-

Why the change to R403.6?

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to to ensure whole house mechanical ventilation continues to be required and installed

Why The change to IRC 303.4?

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to ensure whole house mechanical ventilation continues to be required and installed. In a companion change RB71-19, I have proposed changes to IRC R303.4 as a correlary to this change in the IECC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There should be no cost implication associated with the adoption of this proposed language. Dwellings will continue to need to be tested and testing prices will not change due to an additional option for how to express the results of the test.

Proposal # 5276
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

**DWELLING UNIT.** A single unit providing complete independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

**RESIDENTIAL BUILDING.** For this code, includes detached one- and two-family dwellings and townhouses as well as Group R-2, R-3 and R-4 buildings three stories or less in height above grade plane.

Add new definition as follows:

**DWELLING UNIT ENCLOSURE AREA.** The sum of the areas of the walls, floors, ceilings, and any other building element assemblies that enclose the conditioned space of the dwelling unit or provide a boundary between the conditioned space of the dwelling unit and exterior or adjacent conditioned or unconditioned spaces.

**R402.4 (IRC N1102.4) Air leakage (Mandatory).** The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

**R402.4.1 (IRC N1102.4.1) Building thermal envelope.** The building thermal envelope shall comply with Sections R402.4.1.1 and R402.4.1.2. The sealing methods between dissimilar materials shall allow for differential expansion and contraction.

Revise as follows:

**R402.4.1.2 (IRC N1102.4.1.2) Testing.** The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals).

**Exception:** For dwelling units other than detached one-family dwellings, an air leakage rate not exceeding 0.3 cfm per ft² of the dwelling unit enclosure area shall be an accepted alternative in all Climate Zones. Testing shall be conducted in accordance with ANSI/RESNET/ICC 380, ASTM E779 or ASTM E1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals).

Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

**R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory).** The building Each dwelling unit shall be provided with ventilation that complies with mechanical ventilation. The mechanical ventilation system shall comply with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

**Reason:** Why allow a different metric than ACH50?
A surface area based metric is more appropriate than a volume based metric since air-sealing varies directly with the amount of surface area. Depending on the floor plan, two apartments can have total surface area that differ by 15-25%, but still have the same volume and floor area. The
current volume-based metric (3 or 5 ACH50) results in the same maximum air leakage allowed for these two different apartments, yet one
apartment has significantly more surface area which to seal, making it inherently more difficult to achieve compliance. While this logic holds true for
detached homes as well, in this proposal, this metric is being proposed for attached units only. Other proposals have been submitted to propose this
metric for detached homes as well.

Is this cfm50/ft2 metric used anywhere else?

The metric proposed in this "Exception" has been successfully used in above-code multifamily programs since 2005 (ENERGY STAR Multifamily
High Rise, LEED, and Passive House). It is also used in the Commercial provisions of IECC (C402.5), but at 75 Pa instead of 50 Pa. For
comparison, 0.3 cfm50/ ft2 of dwelling unit enclosure area proposed here is the same as the commercial requirements for EXTERIOR envelope (0.4
cfm75/ft2), but this proposal requires it on ALL surfaces of the apartment enclosure, resulting in dwelling units that are individually sealed as tight as
a commercial building's exterior envelope.

Will this create a challenge for code officials or individuals conducting the tests?

This metric is already reported on many air leakage reports that code officials receive today, so there is no change in reporting or effort in
conducting the tests. Testing results are measured in CFM50, not ACH50. This CFM50 test value is translated into multiple metrics, and just as
easily can be translated to CFM50/ft2 as ACH50.

Will this result in more efficient buildings?

While many focus on air leakage to the outdoors, air leakage within a multifamily building also results in energy losses. Conditioned air can leak
to/from a dwelling unit to another vacant (unconditioned) unit, or the unheated stairwell or elevator shaft, the non conditioned corridor, or laundry
room.

This proposal seeks to provide a reasonable alternative metric that will encourage builders to air seal and test successfully at the dwelling unit level
instead of testing at the building level and potentially missing significant leakage pathways within the building that cause energy loss. Testing at the
dwelling unit will result in tighter dwelling units and in the process, tighter buildings.

Why the change to R403.6?

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section
was edited to avoid any potential loophole.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Since this metric is simply an alternative to the current dwelling unit tests allowed, there is no change in costs.
2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new text as follows:

DWELLING UNIT ENCLOSURE AREA. The sum of the area of ceiling, floors, and walls separating a dwelling unit’s conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. Wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above.

Revise as follows:

R402.4 (IRC N1101.6) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour or 0.28 cubic feet per minute (CFM) per square foot (ft²) of dwelling unit enclosure area in Climate Zones 1 and 2, and three air changes per hour or 0.17 CFM per (ft²) of dwelling unit enclosure area in in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

SECTION R403 (IRC N1103)
SYSTEMS

R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory). The building Each dwelling unit shall be provided with mechanical ventilation that complies. The mechanical ventilation system shall comply with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

Reason: Air changes per hour (ACH) is a volumetric metric that is useful for air quality measurements in buildings but is not the correct expression of air leakage from an energy or building durability perspective. This proposal introduces the ability to use an alternative cubic foot per minute (CFM) per square foot (ft²) of dwelling unit enclosure area metric for measuring air leakage in a building. In this way, the air leakage measured at 50 Pascals divided by the building surface area is used to assess the airtightness of the construction and building envelope. Unlike ACH, a CFM/ ft² of dwelling unit enclosure area metric normalizes the building air leakage per unit of building envelope surface area; the actual location where air is infiltrating or exfiltrating the building. To this end, the proposal also defines “Dwelling Unit Enclosure Area” as the sum of the area of ceiling, floors, and walls separating a dwelling unit’s conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. In addition, the definition offers guidance to further understand the measurement that must take place to calculate the dwelling unit enclosure area. This guidance states that the wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above. Lastly, the proposal ensures that the intent of the code, to ensure that the structure is built tight and ventilated correctly with mechanical ventilation, is maintained. If an additional option is adopted into the code, as proposed, then ventilation must also be ensured regardless of how air tightness of the structure is expressed.

Since 1980, The Energy Conservatory, has not only been a leader in air leakage science, but also one of the prominent manufacturers of the blower door air measurement tool. In their article, “Which Is A Better Metric For Measuring Airtightness: ACH @ 50 Pa Or CFM/ Ft² Of Surface Area @ 50 Pa?”, which is adapted and added to in this reason statement, we get the basis of the argument for the introduction of a new metric into the International Energy Conservation Code for the measurement of air leakage.
To paraphrase, when measuring the airtightness of a building the objective is to learn how much leakage is occurring across the building’s enclosure area. It is analogous to moisture permeability or the measurement of moisture across the building’s enclosure area and thermal transmittance, the rate at which heat is transferred across the building enclosure area. The rate of air leakage or tightness does not depend on the volume of the structure as defined by the building’s enclosure area but does depend on the holes associated with the surface area of the structure. Air permeability of a material is typically measured as the flow per area at a given pressure difference across the material. U value measurements are similar. If we want a metric to use to measure the airtightness quality of construction of the exterior enclosure of buildings it makes sense to use a metric that equates flow to the size and number of holes in the building’s thermal enclosure.

The article continues with an example to help demonstrate how volume is not proportional to surface area:

Comparison between ACH50 and CFM50/ft² for a 2000 ft² home at 3 ACH50

House Is 50 X 40 X 8
Volume = 16,000 ft³
Surface Area = 50 X 40 X 2 + 180 X 8 = 5440 ft²
CFM50 = (3 X 16000)/60 = 800 CFM
CFM50/ft² = 800/5440 = 0.147 CFM50/ft²

Increase height to 2 story at 3 ACH50
House Is 50 X 40 X 16 Volume = 32,000 ft³
Surface area = 50 X 40 X 2 + 180 X 16 = 6880 ft²
CFM50 = (3 X 32000)/60 = 1600 cfm
CFM50/ft² = 1600/6880 = 0.233 CFM50/ft²

In this example, when the volume is doubled, the surface area increased by 26%. And when the ACH50 stays the same, the CFM/ ft² of surface area increased by 58%. I have attached an Excel spreadsheet calculator that further defines the disconnect between ACH and CFM/ ft² of surface area to further elaborate the issue. In the attached calculator you can change the ratio of width and length of the building to see the effect on the resulting expressions of air leakage. An independent yet similar calculator can be found at this Residential Energy Dynamic link http://www.residentialenergydynamics.com/REDCalcFree/Tools/AirLeakageMetrics

The primary purpose of this code change proposal is to introduce the CFM/ft² of surface area metric into the code. Deciding on where to set the minimum allowable leakage rate is difficult largely due to the earlier volume and surface area discussion. Both tests are performed at a pressure differential of 0.2 inch water gauge (50 Pa), which is the traditional residential testing pressure so an attempt was made to align the introduction of a CFM/ft² of surface area metric with the existing ACH50 metric of 3 and 5 air changes per hour. ACH being a volumetric measurement penalized small volume dwelling units so a decision was made to concentrate on a size range of dwellings between 2500 and 5500 square feet. By doing this and using the attached conditioned floor space to shell area calculator we were able to see that little variation occurred between ACH and CFM/ft² of surface area metric when changing the size ratio of the modeled house within this house size range. By rounding up, the proposal is using .17 CFM/ft² of surface area metric to align with 3 ACH and .28 CFM/ft² of surface area metric to align with 5 ACH. By using these numbers, small volume homes, while not having a volumetric penalty, are allowed to be a little more leaky and large volume homes must achieve just about the same level of tightness if not a slight bit more. As the average home size in the United States is approximately just less than 2500 square feet this code change proposals purpose of introducing a better measurement metric without removing the codes traditional measurement methodology, provid additional flexibility while maintaining similar stringency.

The Energy Conservatory suggests that the use of Air Changes per Hour at 50 Pa (ACH50) started approximately 60 years ago by researchers who were interested in ways to predict the natural infiltration rate of buildings, which at the time was most commonly measured in Air Changes per Hour. At the time air quality in buildings was being studied and the metric made sense. If a pollutant is released in a building, the time for the concentration to decay by a certain percentage depends on the infiltration measured in air changes per hour. The analysis of a tracer gas decay test gives a result in air changes per hour. So, when they started measuring airtightness, for use in estimating natural infiltration in air changes per hour, it made sense to use ACH50 as the metric.

However, as discussed earlier, two homes with the same volume can have very different surface areas and holes associated with the building.
enclosure area.

Value is gained by including a surface area-based metric in that air-sealing varies directly with the amount of surface area not the amount of volume in the dwelling. Two buildings can have surface areas that differ by 15%, but have the same volume and the current metric offers the same leakage allowance. Therefore, if the purpose of measuring air leakage is to determine something about the construction quality, air leakage rate, energy efficiency and building durability the metric should be associated with the flow of air through holes in the enclosure. To quantify these things ACH is the wrong metric. It does not tell you anything about the quantity and air leakage through holes in the building. Conversely, the CFM/ ft² of surface area metric concretely expresses the quantity of air leakage through the building's exterior enclosure. When an enclosure is tight more energy is conserved as well as allowing better control and predictability of air flow, thermal flow, and moisture flow.

Many standards are now using square foot of enclosure area instead of ACH. Examples include EnergyStar, US Army Corp of Engineers, LEED, US Passive House and ASHRAE 62.2. This proposal is the first step to bring this better expression of air leakage into the code. It has been created in such a way that options are maintained allowing jurisdictions and building professionals flexibility in defining air leakage requirements.

Link to Energy Conservatory article from which portions of this reason statement have been added:

https://support.energyconservatory.com/hc/en-us/articles/204176240-Which-is-a-better-metric-for-measuring-airtightness-ACH-50-Pa-or-CFM-ft-
of-surface-area-50-Pa-

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There should be no cost implication associated with the adoption of this proposed language. Dwellings will continue to need to be tested and testing prices will not change due to an additional option for how to express the results of the test.

Proposal # 4783

RE92-19
Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code
Revise as follows:

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour, or 0.32 cfm/ft² of enclosure bounding the dwelling for dwellings 1,600 square feet or less, in Climate Zones 1 and 2, and three air changes per hour, or 0.23 cfm/ft² of enclosure bounding the dwelling for dwellings 1,600 square feet or less, in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Reason: All homes and apartments are required to be built tight. What is the most appropriate measurement of tightness is open for debate even within the Code where the metric is dependent on which section being referenced. The different metrics are important though because none of them are perfect and some are more applicable to one building type or another. For example, we believe that small homes and apartments penalized by the ACH metric. A home that is 1,600 sq. ft vs. a home that is 3,000 sq. ft can have the same level of attention to detail regarding the air sealing of a home, yet due to the decreased volume of the smaller home, the smaller dwelling will have a much harder time meeting its ACH target. When volume is the deciding factor in the air leakage, this will always be the case. This built-in bias for larger homes with the ACH metric is because the ratio of surface area of the envelope (or walls bounding the dwelling) to the volume is not a linear relationship. Further the number of penetrations required by Code that can not be sealed effectively (exhaust ducts, mechanical ventilation intakes, fire-sprinkler penetrations, etc.) and the instances of penetrations that result in inadvertent leakage (plumbing penetrations, electrical penetrations, windows, doors, etc.) may be similar for a small dwelling as a large dwelling. For example: A house that is 1,000 square feet or 6,000 square feet will most often have one kitchen with all its associated openings and penetrations. The infiltration metric we are proposing is derived from the ACH equivalencies accepted in ICC 700-2020 (which is currently in its first Public Comment). We are proposing that this equivalency only be accepted for dwellings under 1,600 sq. ft. though because 1) we believe the small dwellings are the ones being penalized by the ACH metric and 2) this leakage metric would result in less stringent leakage targets at larger dwelling volumes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This code change will decrease the cost of construction for dwellings under 1600 sq. ft. by setting a air leakage target that is meaningful and achievable.
2018 International Energy Conservation Code

R402.4 Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

R402.4.1.2 Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Add new text as follows:

R402.4.1.3 (IRC N1102.4.1.3) Testing Garage Separation. The integrity of the air barrier assembly between dwelling units and attached garages shall pass a two-part test.

1. While conducting the air leakage test as described in Section R402.4.1.2 the air barrier separation between the house and the garage shall be tested to ensure that the house in reference to the garage is ≥ 45 Pascals of pressure when the house is held at 50 Pascals of pressure in relation to outside. All operable garage openings to the outside shall be closed during the test.
2. If test number 1 passes, the test shall be performed a second time with the garage vehicle door open to the ambient outside. The two test results shall not differ by more than 6 percent.

Reason: The energy code, like all code, is about health, safety, comfort, durability, as well as efficiency. The garage is the largest potential source of pollutants and carbon monoxide in the house and it has been codified in table R402.4.1.1 to ensure that the air in the garage is separated from the house. Air from an attached garage can enter the living space of the home if there are bypasses in the air barrier between the two spaces and if the home is at a negative pressure with respect to the garage. Negative pressures may be due to natural forces or to mechanical depressurization of the house with respect to the garage caused by appliances like rangehood fans, clothes dryers, bath fans, crawlspace ventilation or whole house ventilation systems, as well as, unbalanced HVAC systems. Unfortunately, there is no way to be sure that separation has been achieved, in this location, unless the separation is tested. Fortunately testing for separation between the house and garage is simple and is made even more practical due to the requirement to blower door test for every home. The surest way to keep garage pollutants out of the house is to build a detached garage. Since most houses are designed with attached garages, planning ahead of construction to make sure a continuous air barrier is installed between the house and the garage makes sense. This proposal will promote such planning.

To ensure that there is not a false positive result Building America research has determined that the test requires two steps. First, while the house is at 50 Pascals of pressure with regards to outside during the blower door test a zonal pressure test is performed by installing a tube between the house and the garage. (Usually under the door between the house and the garage) If the garage is clearly outside, the measurement between the house and the garage should also be 50 Pascals of pressure. The closer the measurement is to zero the more connected the garage is to the house. This code proposal requires that the results of the first test be ≥ 45 pascals which is an indication that the air barrier assembly between the house and garage is sound. The first test is performed when all openings between the garage and the outside are closed. Second, this test is repeated with the overhead vehicle door open. If the results of the second test are greater than 6% the connection between the house and the garage tests fails. The rationale for the second test is to guard against false positive results that can occur while performing the first test.

If we continue to require separation between the house and the garage from an energy efficiency perspective, we must also test to ensure it from a health and safety perspective in order to maintain the intent of the IECC. Programs such as the EPA Indoor Air Plus and the DOE Zero Energy Ready Home program have incorporated the protocol described above to test for this separation. In addition, Jurisdictions around the country, such as Fort Collins Colorado have amended the IECC to require this test as they realize the energy and health and safety implications.
People have asked if garage separation is really an issue. Past research, as pointed out in the Building America Program research paper titled “Air Leakage and Air Transfer between Garage and Living Space” says yes. An excerpt of a study done by S.J. Emmerich used in the Building America paper, reports that polluted garage air infiltrated into living quarters was as much as 45% of total house infiltration. See the attached research paper for more evidence of carbon monoxide and other pollutants traveling between attached garages and the house and the bibliography of numerous studies that have documented that pollutants from the garage are capable of migrating into the house.

The problem is that one cannot know for sure if the garage is connected to the house unless one tests. The complexities of the assemblies separating the house and the garage, with dropped ceilings, pipe, ducts, wiring and who knows what else penetrating the buildings thermal envelope and air barrier systems, make it an extremely difficult part of the house to seal. What we do know is that automobiles are the largest source of carbon monoxide in our home and they are parked in attached garages. We also know that other pollutants such as gasoline, pesticides, and paints are stored in attached garages. Therefore, to not test is clearly against the health and safety intent of the code and ultimately places builders and homebuyers at risk.

Air Sealing and Insulating Garage Walls - Code Compliance Brief

Overview:

The intent of this brief is to provide code-specific information about air sealing and insulating garage walls to help ensure that the measure will be accepted as being in compliance with the code. Providing notes for code officials on how to plan reviews and conduct field inspections can help builders or remodelers with proposed designs and installations and provide jurisdictional officials with information for acceptance. Providing the same information to all interested parties (e.g., code officials, builders, designers, etc.) is expected to result in increased compliance and fewer innovations being questioned at the time of plan review and/or field inspection.

As in other parts of the home, sealing and insulating the walls and ceiling of your garage can be an effective way to improve energy efficiency in a home. In addition, properly isolating and air sealing attached garages from the living space is critical for preventing the potential infiltration of carbon monoxide and other contaminants into the home. Open joist bays above the garage that extend into living spaces need to be blocked and air sealed at the garage wall. Seams along the rim joist, top plate, sill plate, and foundation wall should be caulked or sealed. If there is living space above the garage, extra care should be taken to seal all seams and any holes in the subfloor, and any doors between the house and the garage should be weather stripped and have a tight-fitting threshold sweep.

Insulation and air-sealing requirements for garage walls shared with conditioned space are found in the International Energy Conservation Code (IECC) and International Residential Code (IRC). Even though each version of the 2009, 2012, and 2015 IECC/IRC codes has included provisions that the building thermal envelope1 should be durably sealed to limit infiltration, the language related to air barriers and insulation in the 2009 version was somewhat vague and did not specify specific components of the building thermal envelope. The 2012 IECC/IRC added more specific language regarding areas of the building thermal envelope that should be sealed and expanded upon those areas that are now included in the 2015 IECC/IRC as well. This brief provides an overview of the 2009 through 2015 IRC/IECC code requirements related to air sealing and insulating attached garage walls.

Cost Impact: The code change proposal will increase the cost of construction
The cost implication of this proposal is small as this test must be performed at the same time as the blower door test described in section R4052.4.1.2. The garage separation test will add approximately 15 minutes to the testing that is already being performed so may add between $25 and $50. If the test fails it is an indication that already required code air sealing scopes of work are not being performed properly. This should require greater attention to detail rather than additional cost from the air sealing contractor.
2018 International Energy Conservation Code

Add new text as follows:

R402.4.1.3 (IRC N1102.4.1.3) **Sampling options for R2 multifamily dwelling units.** For buildings having three or more dwelling units, a minimum of 15% of the dwelling units in each building must be tested as required by Section R402.4.1.2. Prior to beginning sampling for testing, “Initial Testing” is required for each multifamily property. “Initial Testing” shall consist of the 3rd party testing contractor performing the required tests on at least three consecutive dwelling units. Test results from the “Initial Testing” must satisfy minimum code requirements before sampling is permitted. Dwelling units selected for the “Initial Testing” must be within the same building. Dwelling units selected for “Initial Testing” shall not be included in a “sample group” or counted toward the minimum 15% of dwelling units tested. The building official shall randomly select the three dwelling units for “Initial Testing.” The building official may delegate the random selection to the designated 3rd party testing contractor.

R402.4.1.3.1 (IRC N1102.4.1.3.1) **Sample group Identification and Sampling.** The builder shall identify a “sample group” which may be a building, floor, fire area or portion thereof. All of the dwelling units within the “sample group” must be at the same stage of construction and must be ready for testing. The building official shall randomly select at least 15% of dwelling units from each “sample group” for testing. The building official may delegate the random selection to the designated 3rd party testing contractor.

If each tested dwelling unit within a “sample group” meets the minimum code requirements, then all dwelling units in the “sample group” are considered to meet the minimum code requirements.

Before a building may be deemed compliant with the testing as required, each “sample group” must be deemed compliant with the minimum code requirements. The sum total of all of the tested dwelling units across all “sample groups” shall not be less than a minimum of 15% of the dwelling units in a building.

R402.4.1.3.2 (IRC N1102.4.1.3.2) **Failure to Meet Code Requirement(s).** If any dwelling units within the identified “sample group” fail to meet a code requirement as determined by testing, the builder will be directed to correct the cause(s) of failure, and 30% of the remaining dwelling units in the “sample group” will be randomly selected for testing by the building official, or third-party testing contractor, regarding the specific cause(s) of failure.

If any failures occur in the additional dwelling units, all remaining dwelling units in the sample group must be individually tested for code compliance.

A multifamily property with three failures within a 90-day period is no longer eligible to use the sampling protocol in that community or project until successfully repeating “Initial Testing.” Sampling may be reinstated after at least three consecutive dwelling units are individually verified to meet all code requirements.

A Certificate of Occupancy may not be issued for any building until testing has been performed and deemed to satisfy the minimum code requirements on the dwelling unit(s) identified for testing.

**Reason:** For many multifamily (R2 classifications) projects, it is very costly and time consuming to test each dwelling unit for projects where there may be dozens of dwelling units in each building. Considering that the same tradesman generally constructs a building, it is reasonable to deem that construction practices are consistent and that if a reasonable sampling of units tested pass then all units would pass. These amendments (originally drafted by the North Texas Council of Governments Energy and Green Advisory Board) or are very similar ordinances, have been accepted across Texas by the EHJs including the City of Dallas, the City of Austin, and the City of San Antonio.

**Cost Impact:** The code change proposal will decrease the cost of construction

This code change proposal will streamline the cost and time required to conduct on-site verification of Code which will result in lower testing costs and faster construction timelines.
2018 International Energy Conservation Code

Revise as follows:

R402.4 (IRC N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

R402.4.1 (IRC N1102.4.1) Building thermal envelope. The building thermal envelope shall comply with Sections R402.4.1.1 and R402.4.1.2 through R402.4.1.3. The sealing methods between dissimilar materials shall allow for differential expansion and contraction.

R402.4.1.1 (IRC N1102.4.1.1) Installation (Mandatory). The components of the building thermal envelope as indicated in Table R402.4.1.1 shall be installed in accordance with the manufacturer’s instructions and the criteria indicated in Table R402.4.1.1, as applicable to the method of construction. Where required by the code official, third party shall inspect all components and verify compliance.

R402.4.1.2 (IRC N1102.4.1.2) Testing (Mandatory). The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8 for air leakage. The maximum air leakage rate for any building or dwelling unit under any compliance path shall not exceed 5.0 air changes per hour. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Add new text as follows:

R402.4.1.3 (IRC N1102.4.1.3) Leakage Rate (Prescriptive). The building or dwelling unit shall have an air leakage rate not exceeding 5.0 air changes per hour in Climate Zones 1 and 2, and 3.0 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.

Reason: The purpose of the code change proposal is to increase flexibility by modifying the mandatory value for air leakage to permit limited trade-off against other features of the home and establishing a prescriptive value at the same level as the current mandatory value. Specifically, the proposal would allow a trade-off option for air tightness up to 5 ACH50, while maintaining the baseline prescriptive value for trade-offs at 3 ACH50 in climate zones 3-8. Because the current air leakage requirements are mandatory, builders have limited recourse if a finished home fails to meet the required leakage level or if the size or design features of the home make air tightness more challenging. This proposal will allow air leakage to be traded off up to a designated maximum level through either the performance path or the ERI, as long as builders account for the efficiency losses by improving other building components. If a builder believes that the particular design characteristics or size of a home or dwelling unit will make it more difficult to achieve 3 ACH50, this flexibility will allow the builder to hedge against a failure to meet the prescriptive leakage by implementing modest improvements elsewhere in the home and complying by the performance path or ERI.

This change should improve adoption and enforcement of the code requirements. The proposal responds to complaints that the current mandatory level of air leakage at 3 ACH is too stringent in some cases. It will allow jurisdictions to adopt the 3 ACH requirement with the recognition that if a builder has difficulty meeting it, they have other compliance options. Moreover, this proposal makes the code's air leakage requirements consistent with other requirements where there is a mandatory level at some value above the prescriptive level.
This proposal also clarifies the maximum air leakage rates as 3.0 and 5.0 air changes per hour. While most code users understand the maximum air leakage rates as already being at 3.0 and 5.0 changes per hour, the addition of another digit will pre-empt any “round up” vs. “round-down” arguments from code users, providing additional support for building code officials who are simply trying to enforce the code. This part of the proposal does not change any actual requirements, but rather provides clarification and reduces inconsistency and confusion.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposal is intended to be cost-neutral, but provide increased flexibility and improve compliance and enforcement. In some cases, builders may be able to reduce cost by trading off air leakage for other efficiency improvements.

Proposal # 3993
RE97-19

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code
Revise as follows:

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party that is certified to perform air infiltration testing by a national or state organization. The third-party entity may not be employed, or have financial interest in the company that constructs the building or dwelling unit. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Reason: The International Residential Code (IRC) and International Energy Conservation Code (IECC) includes enhanced emphasis on envelope infiltration and duct leakage. Significant changes in the residential energy requirements include more frequent requirement of performance testing for leakage. Residential Duct systems must be tested unless all ducts and equipment are located within the conditioned space. Envelope testing is required to demonstrate compliance with maximum allowable leakage rate. This language puts the regulatory authority on notice that the testing requires specialized credentials and establishes a conflict of interest baseline.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The code change proposal will not increase or decrease the cost of construction.

Proposal # 4592
RE98-19
IECC: R402.4.1.2 (IRC N1102.4.1.2), TABLE R405.5.2(1) [IRC N1105.5.2(1)]

**Proponent:** William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

**R402.4.1.2 (IRC N1102.4.1.2) Testing.** The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five 5.0 air changes per hour in Climate Zones 1 and 2, and three 3.0 air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

**TABLE R405.5.2(1) [IRC N1105.5.2(1)]**

**SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS**

<table>
<thead>
<tr>
<th>BUILDING COMPONENT</th>
<th>STANDARD REFERENCE DESIGN</th>
<th>PROPOSED DESIGN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Air exchange rate</td>
<td>The air leakage rate at a pressure of 0.2 inch w.g. (50 Pa) shall be Climate Zones 1 and 2: 5.0 air changes per hour. Climate Zones 3 through 8: 3.0 air changes per hour. The mechanical ventilation rate shall be in addition to the air leakage rate and shall be the same as in the proposed design, but not greater than 0.01 × CFA + 7.5 × (N_{br} + 1) where: CFA = conditioned floor area, ft². N_{br} = number of bedrooms. Energy recovery shall not be assumed for mechanical ventilation.</td>
<td>The measured air exchange rate. The mechanical ventilation rate shall be in addition to the air leakage rate and shall be as proposed.</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.093 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

\[ ^{\circ}C = (^{\circ}F - 32)/1.8, \text{ 1 degree} = 0.79 \text{ rad.} \]

- a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

**Reason:** The purpose of this code change proposal is to clarify the current requirements for maximum tested air leakage rates that are already part
of the IECC and to ensure that buildings achieve the efficiency intended by the code. Specifically, the code proposal adds “.0” to the specified requirements to clarify that values above 3.0 or 5.0 are not allowed. While most users understand based on the current language that the air leakage may not exceed 3 or 5 air changes per hour (depending on climate zone), the addition of another digit will pre-empt any claim that a tested value above these maximums, such as 5.4 ACH, will meet the 5 ACH maximum. By cutting off these “round off” arguments from code users, this change will provide additional support for building code officials who are simply trying to enforce the code. This proposed clarification will not change any substantive requirements of the code but will improve compliance and enforcement and eliminate any confusion.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. It merely serves to clarify a current requirement to avoid confusion and inconsistent enforcement.
RE99-19
IECC: R402.4 (IRC N1102.4), R402.4.1.1 (IRC N1102.4.1.1), R402.4.1.2 (IRC N1102.4.1.2), R402.4.1.3 (IRC N1102.4.1.3) (New), R402.4.1.4 (IRC N1102.4.1.4) (New)

Proponent: Joel Martell, representing National Association of Home Builders (jmartell@nahb.org)

2018 International Energy Conservation Code
Revise as follows:

R402.4 (IRC N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.5.

R402.4.1.1 (IRC N1102.4.1.1) Installation (Mandatory). The components of the building thermal envelope as indicated in Table R402.4.1.1 shall be installed in accordance with the manufacturer’s instructions and the criteria indicated in Table R402.4.1.1, as applicable to the method of construction. Where required by the code official, an approved third party shall inspect all components and verify compliance.

R402.4.1.2 (IRC N1102.4.1.2) Testing (Mandatory). The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.
During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

Add new text as follows:

R402.4.1.3 (IRC N1102.4.1.3) Maximum Air Leakage (Mandatory). The maximum Air Leakage permitted shall be 6 ACH in Climate Zones 1 and 2, and 5 ACH in Climate Zones 3 through 8 when tested in accordance with Section R402.4.1.2.

R402.4.1.4 (IRC N1102.4.1.4) Air Leakage Rate (Prescriptive). The building or dwelling unit shall have an air leakage rate not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.

Reason: These modifications remove the mandatory maximum air-tightness requirement and provide designers and builders the flexibility to trade off building tightness with other performance path measures while also providing a limit to that flexibility. Currently the building tightness requirement is mandatory and the 3 and 5 ACH tightness levels, even under ideal circumstances, are very difficult to achieve. This will provide energy neutral tradeoffs for expensive and sometimes unattainable requirements with other building improvements. This proposal does not change the stringency or efficiency of the code; it only increases the flexibility.

DOE has verified that achieving 3 ACH50 is problematic, even in Maryland who has had a 3 ACH requirement for over 3 years (see chart below).
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal will not change the cost of construction only add flexibility.
RE100-19

2018 International Energy Conservation Code

Revise as follows:

R402.4.1.2 (IRC N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope have been sealed.

Exception: For heated, attached private garages and heated, detached private garages accessory to 1- and 2-family dwellings and townhouses not more than 3 stories above grade plane in height, building envelope tightness and insulation installation shall be considered acceptable where the items in Table R402.4.1.1, applicable to the method of construction, are field verified. Where required by the code official, an approved third party independent from the installer shall inspect both air barrier and insulation installation criteria. Heated, attached private garage space and heated, detached private garage space shall be thermally isolated from all other habitable, conditioned spaces in accordance with Sections R402.2.13 and R402.3.5, accordingly.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

R402.2.13 (IRC N1102.2.13) Sunroom insulation. Sunrooms enclosing conditioned space and heated garages shall meet the insulation requirements of this code.

Exception: For sunrooms and heated garages provided with thermal isolation, and enclosing conditioned space, the following exceptions to the insulation requirements of this code shall apply:

1. The minimum ceiling insulation $R$-values shall be R-19 in Climate Zones 1 through 4 and R-24 in Climate Zones 5 through 8.
2. The minimum wall insulation $R$-value shall be R-13 in all climate zones. Walls separating a sunroom or heated garage with a thermal isolation from conditioned space shall comply with the building thermal envelope requirements of this code.

R402.3.5 (IRC N1102.3.5) Sunroom fenestration. Sunrooms and heated garages enclosing conditioned space shall comply with the fenestration requirements of this code.

Exception: In Climate Zones 2 through 8, for sunrooms and heated garages with thermal isolation and enclosing conditioned space, the fenestration $U$-factor shall not exceed 0.45 and the skylight $U$-factor shall not exceed 0.70.

New fenestration separating a sunroom or heated garage with thermal isolation from conditioned space shall comply with the building thermal envelope requirements of this code.

Reason: We, in Illinois and Iowa, have found that the addition of a reasonable, provision regulating "heated garages," results in improved levels of compliance assessment.

Cost Impact: The code change proposal will increase the cost of construction

It is likely that the creation of the thermally-isolated "heated garage" provisions will result in less "illegitimate" applications or "non-applications" for permit and inspection of newly heated, existing garages utilized for either hobby or workshop or rendering during hunting season.
**2018 International Energy Conservation Code**

Revised as follows:

**R402.4.1.2 (IRC N1102.4.1.2) Testing.** The building or dwelling unit shall be tested and verified as having an air leakage rate not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope have been sealed.

**Exception:** For additions, alterations, renovations or repairs to existing buildings, building thermal envelope tightness and insulation installation shall be considered acceptable when the items in Table R402.4.1.1, applicable to the method of construction, are field verified. Where required by the code official, an approved third party independent from the installer shall inspect both air barrier and insulation installation criteria.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, where installed at the time of the test, shall be open.
4. Exterior or interior terminations for continuous ventilation systems shall be sealed.
5. Heating and cooling systems, where installed at the time of the test, shall be turned off.
6. Supply and return registers, where installed at the time of the test, shall be fully open.

**Reason:** Should a bedroom addition to a farmhouse originally constructed in 1950's rural America be required to be blower door tested to 3.0 ACH50? We think not. Accordingly, a reasonable middle ground is offered.

**Cost Impact:** The code change proposal will decrease the cost of construction. While interpreted literally, a blower door test is required for new construction, including additions.
2018 International Energy Conservation Code

Add new text as follows:

R402.4.1.2.1 (IRC N1102.4.1.2.1) Multi-unit buildings and single family attached buildings shall be tested as a single zone, multiple zones, or as individual dwelling units in accordance with ASTM E779.

Reason: This proposal is very clear and straightforward, it helps to clarify testing in multi-unit buildings. The ASTM E779 standard is referenced in R402.4.1.2 and this standard allows for single, or multiple zone testing. This proposal is just adding clarification to the code for a method that is already allowed. Currently the IECC treats low-rise multifamily buildings of three stories or less like single-family homes and multifamily buildings of four stories or more like commercial buildings. Regardless of height, all multifamily buildings have the same airtightness testing complications to address. Large multiple dwelling buildings are often tested as isolated test zones due to the nature of the actual testing procedures and available equipment needed to depressurize large volumes of conditioned space and this proposal would recognize this challenge for those conducting the testing. By approving this proposal, low-rise multifamily buildings, two-unit dwellings and town houses will avoid these complications, but still be held to the same level of performance as high-rise (R-2) residential as well as commercial buildings.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal will not change the cost of construction. It is adds clarification to something that is already allowed in the code.
IECC: R402.4.2 (New),

R402.4.6

(New)

Proponent: Marilyn Williams, representing NEMA

2018 International Energy Conservation Code

R402.4.2 Fireplaces. New wood-burning fireplaces shall have tight-fitting flue dampers or doors, and outdoor combustion air. Where using tight-fitting doors on factory-built fireplaces listed and labeled in accordance with UL 127, the doors shall be tested and listed for the fireplace.

Add new text as follows:

R402.4.6 Electrical and Communication Outlet Boxes (air-sealed boxes). Electrical and communication outlet boxes installed in the building thermal envelope shall be sealed to limit air leakage between conditioned and unconditioned spaces. Electrical and communication outlet boxes shall be tested in accordance with NEMA OS 4, Requirements for Air-Sealed Boxes for Electrical and Communication Applications, and shall have an air leakage rate of not greater than 2.0 cfm (0.944 L/s) at a pressure differential of 1.57 psf (75 Pa). Electrical and communication outlet boxes shall be marked "NEMA OS 4" or "OS 4" in accordance with NEMA OS 4. Electrical and communication outlet boxes shall be installed per the manufacturer's instructions and with any supplied components required to achieve compliance with NEMA OS 4.

Reason: Similar to Section R402.4.5 for recessed lighting a new section for electrical and communications outlet boxes is being proposed to limit air leakage when installed in the building thermal envelope. "Air-sealed boxes" are identified in Table R402.4.1.1. This new section defines an air-sealed box.

Sealing air-barrier penetrations is not always as simple as applying more insulation, caulk, or expanding foam. Electrical and communication outlet boxes, having design features that effective seal the air-barrier penetrations, also reduce potentially undesirable effects that can result from the use of unspecified sealing techniques.

NEMA OS 4-2016, Requirements for Air-Sealed Boxes for Electrical and Communication Applications, was developed by the NEMA Outlet and Switch Box Section. In the preparation of NEMA OS 4, input of users and other interested parties was sought and evaluated.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

An outlet box with an alternative means of sealing needs to be used if a vapor barrier box is not.

Proposal # 4077
Add new text as follows:

**R402.4.6 (IRC N1102.4.6) Replacement fenestration** Where a fenestration unit is replaced, the new unit shall meet the applicable requirements for U-factor and SHGC in Table R402.1.1.

**Reason:** When windows are replaced, many times the replacement window is installed into the existing frame of the existing window. In such a case the existing window frame now becomes part of the wall assembly, and the new frame and window sash are considered a new fenestration product. In such cases this would require the new fenestration product (new frame, sash, glazing etc.) to meet the U-factor requirements of Table R402.1.2 or R402.1.4 of this code. If you are only replacing the glass or one portion of the window, this is not a replacement fenestration, it would then be a repair, and not a replacement.

**Cost Impact:** The code change proposal will increase the cost of construction. Although a replacement window that complies with the newest code will cost more than one that a replacement window that only complies with less stringent, older codes, the cost differential isn’t that significant as compared to the energy savings (pay-back) over the life of the up-to-current-code window.
RE105-19
IECC: R402.5 (IRC N1102.5)

**Proponent:** William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

**R402.5 (IRC N1102.5) Maximum fenestration U-factor and SHGC (Mandatory).** The area-weighted average maximum fenestration U-factor permitted using tradeoffs from Section R402.1.5 or R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 in Climate Zones 1 through 3 shall be 0.50.

**Reason:** The purpose of this code change proposal is to update the mandatory maximum fenestration U-factors and Solar Heat Gain Coefficients (SHGC) permitted in the IECC's tradeoff compliance paths consistent with improvements in prescriptive fenestration values made since the maximums were originally included in the code. The fenestration maximums have been in the IECC since the 2006 IECC, and have provided a critical backstop in the event of trade-offs, helping to ensure reasonable energy efficiency and occupant comfort. Over the 12 years and 4 code update cycles that these backstops have been in place, prescriptive fenestration efficiencies have improved substantially, but the maximum U-factors and SHG Cs have never been updated. To maintain the effectiveness of these backstops, we recommend that they be updated.

The following graphs help to illustrate the growing "gap" between the prescriptive fenestration U-factors and the mandatory trade-off maximum in R402.5. The first graph below shows the improvements in U-factors for climate zones 4-5 over the last several code editions compared to the existing cap, and shows that there is still considerable trade-off flexibility if the trade-off maximum is improved from 0.48 to 0.40. (Note that the cap proposed above is the final data point.)

As shown in the second graph below, the U-factors in climate zones 6-8 follow a similar trend of improvement over the years, while the backstop remains at 0.40. Note that the impact of improving the maximum trade-off U-factor from 0.40 to 0.35 in climate zones 6-8 (as proposed) still leaves substantial trade-off room.
The effect is similar, but even more pronounced for SHGC. As shown in the SHGC graph below, the current SHGC maximum allows builders to essentially double the amount of heat gain (0.25 to 0.50) before hitting the current cap. Improving the SHGC trade-off maximum from 0.50 to 0.40 as we propose above still leaves more trade-off room than was available to builders in 2006 when the cap was originally instituted.

![IECC U-FACTOR REQUIREMENTS IN CZ 6-8 AND TRADE-OFF CAP](image1)

![IECC SHGC REQUIREMENTS AND TRADE-OFF CAP](image2)

We believe that the improved fenestration maximums will be easily met. In fact, based on data recently collected by the U.S. Department of Energy across 8 states, we expect little or no change in homebuilding practices or any impact on homebuilding costs.

- In climate zones 1-3, of the 477 homes sampled, over 98% *already complied* with the proposed SHGC maximum of 0.40.
- Likewise, in climate zones 4-5, of the 468 homes sampled, over 98% *already complied* with the proposed U-factor maximum of 0.40.
- In climate zones 6-8, although DOE did not collect data for these climate zones as part of the Field Studies, the Energy Star program estimates that 83% of fenestration products shipped in 2016 met or exceeded Energy Star requirements (the Energy Star window criteria in 2016 was equal to or lower than a 0.30 U-factor in climate zones 6-8), which still leaves considerable trade-off room below a maximum U-factor of 0.35. See [https://www.energystar.gov/ia/partners/downloads/unit_shipment_data/2016_USD_Summary_Report.pdf?8fd5-1967](https://www.energystar.gov/ia/partners/downloads/unit_shipment_data/2016_USD_Summary_Report.pdf?8fd5-1967).

Anyone who has experienced inefficient uncomfortable windows, either during the winter or summer, understands that this discomfort can lead occupants to adjust the thermostat. The energy impact of adjusting the thermostat is large. The following table shows the increased energy use that results from adjusting the thermostat up or down a single degree in a code-compliant house in each climate zone:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Weighted</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>+1 Degree Heating</td>
<td>4.1%</td>
<td>0.5%</td>
<td>3.0%</td>
<td>4.2%</td>
<td>4.4%</td>
<td>4.7%</td>
<td>4.5%</td>
<td>4.0%</td>
<td>2.9%</td>
</tr>
<tr>
<td>-1 Degree Cooling</td>
<td>3.0%</td>
<td>7.8%</td>
<td>5.3%</td>
<td>3.9%</td>
<td>2.6%</td>
<td>1.8%</td>
<td>1.4%</td>
<td>0.7%</td>
<td>0.4%</td>
</tr>
</tbody>
</table>

Obviously, if an uncomfortable occupant adjusts the thermostat 2 or 3 degrees, the impact will be far higher. Improved window maximums will reduce the likelihood of uncomfortable occupants using excessive heating and cooling to mitigate their discomfort.
We expect this to be an easy-to-implement improvement given the current state of practice, but an important update to the code, that will ensure long-term benefits for all homes with little or no additional cost.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Because this is only a change to a trade-off backstop and not a code requirement (the prescriptive requirement is already more efficient than the proposed new backstop level), and because such a high percentage of homebuilders are likely already meeting or exceeding this requirement, we expect no real cost impact in most cases.
IECC: R403.1.1 (IRC N1103.1.1)

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R403.1.1 (IRC N1103.1.1) Programmable thermostat. The thermostat controlling the primary heating or cooling system of the dwelling unit shall be capable of controlling the heating and cooling system on a daily schedule to maintain different temperature set points at different times of the day, providing a 5:2 (weekdays:weekends) programmable schedule, and at least 2 programmable schedules per day. This thermostat shall include the capability to set back or temporarily operate the system to maintain zone temperatures of not less than 55°F (13°C) to not greater than 85°F (29°C). The thermostat shall be programmed initially by the manufacturer with a heating temperature setpoint of not greater than 70°F (21°C) and a cooling temperature setpoint of not less than 78°F (26°C).

Reason: This code change clarifies the intended operational capability of programmable thermostats by distinguishing between weekday and weekend occupancy schedules along with at least 2 programmable schedules per day. The change also accounts for the capabilities of smart thermostatic controls that auto-adjust based on daily and weekly occupancy patterns. Finally, the manufacturer's initial programmed setting requirement is deleted.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will increase the cost of construction

This requirement will increase costs for the subset of buildings not currently constructed with weekday:weekend programmable thermostats.
R403.1.3 (IRC N1103.1.3) Continuously Burning Pilot Lights The natural gas systems and equipment listed below are not permitted to have continuously burning pilot lights:

1. Fan-type central furnaces.
   **Exception:** Household cooking appliances without electrical supply voltage connections and in which each pilot light consumes less than 150 Btu/hr.
3. Pool heaters.
4. Spa heaters.
5. Fireplaces.

Revise as follows:

R403.10.1 (N1103.10.1) Heaters. The electric power to heaters shall be controlled by a readily accessible on-off switch that is an integral part of the heater mounted on the exterior of the heater, or external to and within 3 feet (914 mm) of the heater. Operation of such switch shall not change the setting of the heater thermostat. Such switches shall be in addition to a circuit breaker for the power to the heater. Gas-fired heaters shall not be equipped with continuously burning ignition pilots.

**Reason:** Standing pilot lights are no longer necessary with many gas-fired appliances offering alternative ignition methods. Some models rely completely on intermittent ignition, while others allow standing pilots to operate for a few hours after shutdown and then use electronic ignition to restart. This proposal saves energy by eliminating the wasted energy of a pilot light during the numerous hours per year when the appliance is non-operational.

**Cost Impact:** The code change proposal will increase the cost of construction. This prohibition is not expected to add significant cost to any gas-fired appliance listed in the proposal. Past efficiency studies have shown $100 increase in price for fireplaces in particular to move from a standard continuously lit pilot light to an intermittent ignition system.
Proponent: Roger Mitchell, Mitchell's Heating and Cooling, representing Self (rogersheating@hotmail.com)

2018 International Energy Conservation Code

Revise as follows:

R403.2 (IRC N1103.2) Hot water boiler outdoor-temperature setback, reset. Hot water boilers that supply heat to the building through one- or two-pipe heating systems shall have an outdoor setback control that decreases the boiler water temperature based on the outdoor temperature. The manufacturer shall equip each gas, oil and electric boiler (other than a boiler equipped with a tankless domestic water heating coil) with automatic means of adjusting the water temperature supplied by the boiler to ensure incremental change of the inferred heat load will cause an incremental change in the temperature of the water supplied by the boiler. This can be accomplished with outdoor reset, indoor reset or water temperature sensing.

Reason: The current standard from the DOE allows for a broader scope in control schemes to meet all the control strategies available in the marketplace. The exception for domestic hot water needs to be included to allow the sale of boilers with integrated domestic hot water production. Currently over 40,000 units are sold per year with domestic hot water coils. The standard from the DOE was updated after the Energy Independence act of 2007 with a implementation date of 2012. This change will bring the IECC code in uniformity with the DOE.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Alignment of the standard to the DOE standard will not increase costs because all of the Heating equipment being installed has the proper controls to meet the DOE standard. No additional components will be required if both standards are the same.
2018 International Energy Conservation Code

Revise as follows:

R403.3 (IRC N1103.3) Ducts. Ducts and air handlers shall be installed in accordance with Sections R403.3.1 through R403.3.7.

R403.3.1 (IRC N1103.3.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 2 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 2 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

R403.3.7 (IRC N1103.3.7) R403.3.6 (IRC N1103.3.6) Ducts located in conditioned space, and insulation. For ducts, Duct work located outside conditioned space, shall be insulated to an R-value of not less than R-8. For duct work to be considered as inside a conditioned space, such ducts shall comply with either one of the following:

1. The duct system shall be located completely within the continuous air barrier and within the building thermal envelope.
2. The ducts shall be insulated within ceiling insulation in accordance with Section R403.3.6 and all of the following conditions shall exist:
   2.1. The duct is air handler located completely within the continuous air barrier and within the building thermal envelope.
   2.2. The duct leakage, as measured either by a rough-in test of the ducts or a post-construction total system leakage test to outside the building thermal envelope in accordance with Section R403.3.4, is less than or equal to 1.5 cubic feet per minute (42.5 L/min) per 100 square feet (9.29 m²) of conditioned floor area served by the duct system.
   2.3. The ceiling insulation R-value installed against and above the insulated duct is greater than or equal to the proposed ceiling insulation R-value, less the R-value of the insulation on the duct.
3. Duct work in floor cavities located over unconditioned space shall have a continuous air barrier on all six sides of the floor cavity and insulation installed in accordance with section R402.2.8 with the addition of insulation fully surrounding the duct and uncompressed R-19 insulation below, or duct work installed in a floor cavity that is insulated per the exception in section R402.2.8.
4. Duct work located within exterior walls shall have a continuous air barrier on all six sides of the wall cavity, a minimum R-10 insulation separating the entire duct from the outside sheathing of the cavity, and the remainder of the cavity insulation fully surrounding the duct to the drywall side.

Reason: Ductwork insulation is dependent on its location. This proposal addresses this issue. By removing Section R403.3.1 Insulation, and combining it with section R403.3.7 duct location, the code becomes more understandable and useable for field practitioners. This newly edited section requires that all duct work located outside of conditioned space regardless of size be insulated to an R-8. This minimum R-value duct insulation is widely available and important to have on ducts located outside regardless of the climate zone in which it is installed or the size of the duct. In addition, it is already the required R-value for duct work located outside per the existing section R403.3.1 As Allison Bailes points out in his Energy Vanguard blog post titled, “The invisible problem with duct insulation” The delta T across the insulated surface can be huge when ducts are located outside the conditioned space. (https://www.energyvanguard.com/blog/invisible-problem-duct-insulation ) In his example ducts located in the attic experienced a delta T of 62°. Although it would be good to raise the minimum required R-value associated with ducts located outside the conditioned envelope this proposal instead incentivizes installation techniques that drive the performance of the duct to be more like that of ducts installed completely inside.

By defining the three possible locations where ductwork can be installed and how to address the insulated assembly so the duct can be considered to be inside conditioned space this proposal increases the energy performance of homes. The three possible locations for duct installation are, one, completely inside the continuous air barrier assemblies, two, completely outside the continuous air barrier assemblies, or three within the continuous air barrier and building thermal envelope assemblies. In the last code cycle, the addition of section R403.3.6 Ducts buried within ceiling insulation addressed the insulation installation issue for ducts located outside of the continuous air barrier assemblies. This code cycle, the hope is that ducts located within the continuous air barrier and building thermal envelope assemblies will be addressed.

The last detail to point out is an energy code compliance issue when using section R405 Simulated Performance Alternative and section R406 Energy Rating Index compliance paths. These pathways include duct location in the software modeling. It has not been clear until the 2018 IECC how to model buried ductwork and the hope now is that the additional language in this proposal will clarify how to model duct work that is installed within the continuous air barrier and building thermal envelope assemblies. If it is installed per this code change proposal is can be considered to be within conditioned space.

See example diagrams for examples of how insulation of duct work installed within the building thermal envelope assembly could be achieved in...
order to locate them within the conditioned space.

The following diagrams illustrate example installations of duct work in garage floor systems or in exterior walls that would be considered to be within the conditioned space.

Example of Ducts in Exterior walls that would be considered within the conditioned space

Duct riser in a 2x6 exterior wall

- Line of the interior air barrier now brings duct into conditioned space
- Foam board must be sealed in place at connections to wood framing. Foam board should be installed at the rim joint were the duct riser transitions to with an elbow to a boot or floor run.
- It is usual to taper to a 7” oval to accommodate the flow of a 4” round design run.
- Seal duct penetration through top and bottom plates
Supply Duct Riser in an Exterior Wall – Solution 3

For situations where a wall cannot be bumped out into the conditioned space of the home:

In a 2x6 wall cavity an oval duct should be installed to the inside of the framed cavity. 2 inches of foam board (minimum R-10 expanded polystyrene or R-14 Polyisocyanurate) should be installed adjacent to the exterior sheathing and sealed to the side studs, top, and bottom plate of the cavity. This creates continuous insulation on the exterior side of the cavity, along with an interior and exterior air barrier which allows the duct to perform as if it has been installed completely inside the thermal envelope. The remaining space in the cavity must be blown with insulation encapsulating the duct except that edge that might be adjacent to the interior drywall. The duct must be air sealed with expanding foam where it penetrates the top and bottom plate.

Example of Duct in wall between house and garage

Seal duct to penetration through top and bottom plate
Blown insulation or two layers of R-15 batts:
1-cut around duct 2-continuous across garage side of cavity
Example of Duct in floor system that would be considered within the conditioned space.

**Ductwork in floor over garage**

- No minimum R-value requirement between ductwork and conditioned space.
- Subfloor + wallboard encapsulate insulation.
- Soffit is completely filled with blown insulation. Minimum R-19 insulation required below duct.
- Duct is located within the thermal boundary and considered to be inside conditioned space. Separate duct insulation sleeve not required.

**Ductwork in garage soffit, adjoining conditioned space, living space above - Solution 2**

- "Wall" of soffit must be full of insulation, meet exterior wall R-value minimum.
- Interior sheathing and exterior wallboard fully encapsulate insulation.
- Duct is located inside the thermal boundary, in conditioned space. No insulation is required on the ductwork.

NOTE: This approach is only approved if BLOWN insulation is used to completely fill the soffit.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal provides new installation guidance and a definition of when a duct is considered to be inside conditioned space that will increase the energy efficiency of a house with better insulated ducts when installed within the continuous air barrier and building thermal envelope assemblies. Ductwork must be insulated and installed per manufacturer instruction. Also, insulation currently must fully surround obstructions like ductwork that is installed in a cavity. So, no additional cost should be expected with the approval of this proposal.
IECC: R403.3.2 (IRC N1103.3.2)

**Proponent:** David Bixby, Air Conditioning Contractors of America, representing Air Conditioning Contractors of America

2018 International Energy Conservation Code

R403.3.2 (IRC N1103.3.2) Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.

**Exception:** Ducts or portions thereof located completely inside the building thermal envelope.

**Reason:** When ductwork is located inside a building’s thermal envelope, any duct leakage from unsealed ductwork enters an already conditioned space within the building thermal envelope. Therefore, no energy loss occurs that is directly related to the sealed and/or unsealed air leakage through the building envelope and not by an unsealed duct in a conditioned space. Although sealing ductwork located inside the building’s thermal envelope provides better comfort for the homeowner, it has no impact on energy efficiency or economic benefits. When discussing building energy efficiency and economic benefits, a homeowner should focus on reducing building leaks, better insulation, windows, and doors, as these are areas where building energy efficiency is lost at the building envelope, not by sealing ductwork in a conditioned space.

**Cost Impact:** The code change proposal will decrease the cost of construction
The proposal will potentially eliminate the need to seal ducts under the conditions specified in the exception, thus reducing the cost of construction in those situations.
RE111-19

IECC: R403.3.1 (IRC N1103.3.1), R403.3.1.1 (IRC N1103.3.1.1) (New), R403.3.1.2 (IRC N1103.3.1.2) (New), R405.2 (IRC N1105.2), R406.2 (IRC N1106.2)

Proponent: David Collins, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R403.3 (IRC N1103.3) Ducts. Ducts and air handlers shall be installed in accordance with Sections R403.3.1 through R403.3.7.

R403.3.1 (IRC N1103.3.1) Insulation (Prescriptive). Ducts shall be insulated in accordance with Sections R403.3.1.1 or R403.3.1.2. Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

Add new text as follows:

R403.3.1.1 (IRC N1103.3.1.1) Supply and return ducts not completely in thermal envelope (Mandatory). Ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

R403.3.1.2 (IRC N1103.3.1.2) Supply and return ducts in the building (Prescriptive) Supply and return ducts partially or fully inside the building shall be insulated as follows:

1. Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter.
2. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions of ducts located completely inside the building thermal envelope in accordance with section R403.3.7.

Revise as follows:

R405.2 (IRC N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

R406.2 (IRC N1106.2) Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

Reason: This proposal consolidates all duct insulation requirements within one section. The requirements for ducts not completely inside of the thermal envelope of the proposed R403.3.1.1 are currently identified as mandatory in both R405.2 and in R406.2, (in a confusing exception) and are labeled as such in this proposal.

The current Sec. R403.3.1 prescriptive insulation requirements for ducts partially or fully inside the building are separated into the proposed R403.3.1.2 (1) requirements for ducts in attics and R403.3.1.2 (2) ducts within other portions of the building.

The current exception to insulation requirements for ducts located completely inside the thermal envelope is maintained but a reference to the applicable section, R403.3.7, is provided for clarity.

Consolidation of requirements will make the code easier to use and enforce.

Note: that companion proposals submitted by the SEHPCAC eliminate the use of the ‘mandatory’ (non-tradeable) and ‘prescriptive’ (tradeable) labels in favor of tabular identification of ‘mandatory’ sections. ICC staff have stated that if both proposals are approved the ‘mandatory’ label will be editorially deleted in favor of the new R405.2 and R406.2 tabular listings. Since all ‘mandatory’ sections would be identified in those new tables no sections will need to be separately identified as ‘prescriptive’ and those labels can also be removed.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green
Construction Code (IGCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is a reorganization of current provisions for greater clarify and enhanced enforcement. There are no proposed changes to the requirements.

Proposal # 4459

RE111-19
2018 International Energy Conservation Code

R403.3 (IRC N1103.3) Ducts. Ducts and air handlers shall be installed in accordance with Sections R403.3.1 through R403.3.7.

R403.3.1 (IRC N1103.3.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to an $R$-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

R403.3.2 (IRC N1103.3.2) Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.

R403.3.2.1 (IRC N1103.3.2.1) Sealed air handler. Air handlers shall have a manufacturer's designation for an air leakage of not greater than 2 percent of the design airflow rate when tested in accordance with ASHRAE 193.

Revise as follows:

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer's air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.
2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

- A duct air leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.
- A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m$^2$) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m$^2$) of conditioned floor area.
2. Postconstruction test: Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m$^2$) of conditioned floor area.

3. Test for ducts within thermal envelope: Where all ducts and air handlers are located entirely within the building thermal envelope, total leakage shall be less than or equal to 8.0 cubic feet per minute (226.6 L/min) per 100 square feet (9.29 m$^2$) of conditioned floor area.

Reason: The purpose of this code change proposal is to help ensure occupant comfort, proper heating and cooling system performance, and resulting long-term energy savings by requiring a duct leakage test for all new homes, including homes with all ducts inside conditioned space. This action will also help reduce the likelihood of builder callbacks for poorly-functioning, uncomfortable HVAC systems. The IECC currently exempts homes from duct testing requirements where the air handler and all ducts are located inside conditioned space. Although moving all ducts inside conditioned space may have a positive impact on energy efficiency overall, this practice alone cannot guarantee that the ducts will be tight enough to deliver conditioned air to all occupied areas of the home. Uncomfortable occupants commonly adjust thermostat settings to counteract the effect of poor delivery of conditioned air, leading to huge losses in energy efficiency. And these homes are at far greater risk for builder callback. This proposal will improve building quality and keep occupants more comfortable by requiring a duct test for all new homes, although the allowable...
leakage rate will be set at twice the prescriptive rate when all ducts are located inside conditioned space. Duct leakage rates can be extremely high when ducts are not tested. We do not believe that builders intentionally cut corners in duct sealing when they know that the system will not be tested. However, without an objective test as a means of quality assurance, even careful builders may not be aware of missed connections or poor sealing. In a recent DOE field study of residential homes in Kentucky, homes received duct leakage tests even where all supply and return ducts were located inside conditioned space. The results were striking – of the 24 homes tested (that would have qualified for the test exemption under the IECC), all 24 homes had higher leakage rates than the 2018 IECC requirement. Tested duct leakage for these homes averaged 18.5 cfm/sq.ft., with individual homes ranging from 6.26 cfm/sq.ft. to as high as 40.36 cfm/sq.ft. See https://www.energycodes.gov/compliance/energy-code-field-studies. We note that 40 other homes in the same study were required to be tested (because at least some ducts were located outside conditioned space), and these homes achieved leakage rates of 9.7 cfm/sq.ft., on average – roughly half the leakage rate of homes that qualified for the exemption. Obviously, this is a small sample size, but the Field Studies found similar results in Pennsylvania, where “exempt” homes (with all ducts inside conditioned space) averaged almost 31 cfm/sq.ft. leakage, while homes required to be tested averaged almost 18 cfm/sq.ft. leakage.

<td>18.46</td>
</tr>
</tbody>
</table>

Although the results vary across the states sampled, these results point to a shortcoming in the IECC’s “complete exemption” approach to homes with all ducts inside conditioned space.

Although most energy modeling software does not capture the occupant-level impact of poorly-sealed ducts, anyone who has lived or worked in a building with leaky ducts understands that discomfort can lead occupants to adjust the thermostat. The energy impact of adjusting the thermostat is huge. The following table shows the increased energy use that results from adjusting the thermostat up or down a single degree in a code-compliant house in each climate zone.

<table>
<thead>
<tr>
<th>Increased Energy Use Resulting from Thermostat Adjustment</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>-1 Degree Cooling</td>
</tr>
</tbody>
</table>

Obviously, if an uncomfortable occupant adjusts the thermostat 2 or 3 degrees, the impact will be far higher, and could essentially negate many of the efficiency gains made in the IECC over the last decade.

The concept of requiring a test for all new homes is not new. DOE’s Building America Program recommends that “[e]ven in conditioned space, ducts should be insulated to reduce the risk of condensation and mold. They should be tightly sealed and tested for leakage.” See https://www.energy.gov/sites/prod/files/2014/01/f6/1_1g_ba_innov_ductsconditionedspace_011713.pdf. Likewise, the International Association of Certified Home Inspectors recommends that ducts be located entirely within conditioned space and tested to ensure air tightness. Air leakage rates at air handlers, even when all ducts are located in conditioned space, can lead to significant reduction in comfort, leading homeowners to adjust the thermostat and significantly increase energy use. See https://www.nachi.org/inspecting-hvac-cabinet-seams-air-leakage-sealing.htm.

Cost Impact: The code change proposal will increase the cost of construction. This proposal will require duct testing and meeting a modest duct tightness level in the limited subset of homes that are currently exempt from the test requirement in the IECC. However, we believe the added value in quality control for builders and the likely positive impact on occupant comfort...
and energy savings will easily outweigh the cost of the test and any remedial efforts to improve duct tightness.
RE113-19

IECC: R403.3.3 (IRC N1103.3.3)

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code

Revise as follows:

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.

2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the approved third party conducting the test, that has been certified to perform duct testing by a national or state organization, and provided to the code official. The approved third party may not be employed or have any financial interest in the company the constructing the building.

Reason: The International Residential Code (IRC) and International Energy Conservation Code (IECC) includes enhanced emphasis on envelope infiltration and duct leakage. Significant changes in the residential energy requirements include more frequent requirement of performance testing for leakage. Residential Duct systems must be tested unless all ducts and equipment are located within the conditioned space. Envelope testing is required to demonstrate compliance with maximum allowable leakage rate. This language puts the regulatory authority on notice that the testing requires specialized credentials and establishes a conflict of interest baseline.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This code proposal does not change the requirement for duct testing to be conducted and therefore should not increase or decrease the cost of construction. It does however change who conducts the test such that the installation contractor is not self-certifying compliance with Code. This change aligns section R403.3 for duct leakage testing with Section R402.4 Air Leakage such that both would require that testing be conducted by an approved third party.
2018 International Energy Conservation Code

Revise as follows:

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested in accordance with ANSI/RESNET/ICC 380 or ASTM E1554 to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.
2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.
2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Add new text as follows:

E1554/E1554M-13:
Standard Test Methods for Determining Air Leakage of Air Distribution Systems by Fan Pressurization

Reason: Section 403.3.3, Duct testing, currently provides no guidance for testing duct systems to determine if they meet the maximum duct leakage rate. The current code language sets a duct leakage metric and essentially leaves it up to those that are testing the system to determine how to arrive at the results. The lack of guidance can lead to inconsistent test results from house to house. This code change proposal solves this problem by requiring testing to conform to ANSI/RESNET/ICC Standard 380 - Standard for Testing Airtightness of Building Enclosures, Airtightness of Heating and Cooling Air Distribution Systems, and Airflow of Mechanical Ventilation Systems OR ASTM E1554. Standard 380 provides a standardized methodology that is currently in use throughout the industry. The methodology will provide consistent results that can be replicated by testing organizations and enforcement personnel.

RESNET/ICC Standard 380 has been developed to provide a consensus national standard for consistent measurement of several air-flow related residential building metrics. It builds off of existing American National Standards to provide standard procedures essential to the evaluation of the energy performance of residential buildings energy.

ASTM Standard E1554-13, was most recently re-approved in 2018 and describes 4 different test methods (A, B, C, and D) for performing a duct leakage test. Method A requires multi-point testing of both the enclosure and the distribution system at a range of 5 to 50 Pa in 5 Pa increments using both pressurization AND depressurization of the building enclosure AND distribution system. Method B requires a physical separation of the supply and return distribution systems and that each are tested separately at a 25 Pa pressure difference, while measuring the pressure difference between any buffer zones and the outside. This procedure requires several iterations of each test (supply, return, buffer zone). Method C measures distribution system leakage to the outside using a 25 Pa pressure difference across the building enclosure with reference to the outside using a location sheltered from wind and sunshine. The distribution system is tested at a 25 Pa pressure difference with reference to the outside and the recording of inside temperature, outside temperature, and barometric pressure at the start and end of each test. This method requires testing under pressurization, while Standard 380 allows pressurization or depressurization (field conditions may require depressurization in order to maintain seals on the supply outlets and return inlets). Method D measures total distribution system leakage at a 25 Pa pressure difference with reference to the outside without using a fan (blower door) to create a 25 Pa pressure difference across the building enclosure to isolate leakage to the outside.

Although Standard 380 is a more industry-recognized standard, either Standard 308 or ASTM E1554 provide a consistent methodology for testing the air leakage of duct systems.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The protocol for duct testing described in Standard 380 is consistent with the testing protocols presented in RESNET certifications for HERS raters and also with the Duct and Envelope Testing (DET) training sessions that are being deployed in several states to meet the testing needs of the IECC. This protocol is considered industry standard and will not increase the time for testing ductwork, so the cost of testing will not increase, but will lead to more compliant duct systems for duct testing professionals that may not be following a protocol. The protocol does not change the target duct air leakage rate so there are no additional costs to seal the duct system to make it code compliant. ASTM E1554 is offered as an alternative because it is another standard for testing duct systems for leakage.

**Analysis:** A review of the standard proposed for inclusion in the code, ASTM E1554/E1554M-2013, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
RE115-19
IECC: R403.3.3 (IRC N1103.3), R403.3.4 (IRC N1103.3.4)

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

R403.3 Ducts. Ducts and air handlers shall be installed in accordance with Sections R403.3.1 through R403.3.7.

R403.3.1 Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to an R-value of not less than R-8 for ducts 3 inches (76 mm) in diameter and larger and not less than R-6 for ducts smaller than 3 inches (76 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to not less than R-6 for ducts 3 inches (76 mm) in diameter and not less than R-4.2 for ducts smaller than 3 inches (76 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

R403.3.2 Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.

R403.3.2.1 Sealed air handler. Air handlers shall have a manufacturer’s designation for an air leakage of not greater than 2 percent of the design airflow rate when tested in accordance with ASHRAE 193.

Revise as follows:

R403.3.3 (IRC N1103.3) Duct testing (Mandatory). The ductwork in a building or dwelling unit shall be pressure tested to determine air leakage. The maximum total leakage rate for ducts in any building or dwelling unit under any compliance path shall not exceed 8.0 cfm (226.5 L/min) per 100 square feet (9.29 m²) of conditioned floor area. Testing shall be conducted at the rough-in stage or post-construction by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.
2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.
2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4.0 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3.0 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.
2. Postconstruction test: Total leakage shall be less than or equal to 4.0 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

Reason: The purpose of this code change proposal is to help ensure long-term energy savings, occupant comfort and promote good building quality by establishing a maximum level of duct leakage permitted as a trade-off backstop for duct tightness. We propose a backstop that would still permit substantial flexibility – double the allowable leakage rate as the prescriptive requirement -- but that would establish a “worst case scenario” for all tested homes in all compliance paths.

There is currently no upper limit on duct leakage in the IECC. In the 2012 IECC, all ducts (except those in conditioned space) were required on a mandatory basis to meet the prescriptive levels. The mandatory nature of the requirement was removed in 2015, allowing duct tightness to be fully traded off for other efficiency measures. We believe some trade-off is acceptable, but that a minimum level of duct tightness is necessary to ensure some reasonable level of duct performance occurs in the home. When ducts are excessively leaky, there is no assurance that conditioned air is...
provided where it is needed for adequate comfort. The failure to properly distribute conditioned air is likely to result in excess energy usage when the occupants adjust the thermostat to counter an inadequate distribution of conditioned air. Many of the intended benefits of high-performance homes are negated if occupants are uncomfortable and adjust the thermostat in response.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal is intended to be cost-neutral, since it does not change the prescriptive requirement, but will ensure that at least some reasonable attention has been paid to duct tightness. Because the new backstop will only apply in homes that are already required to have ducts tested, the only potential cost would come in a situation where a builder has traded away the efficiency of the duct system for an improvement elsewhere in the home at a lower cost such that the home would not even meet the weaker duct tightness level proposed here. However, in such cases, we believe owners and occupants of homes will benefit substantially from having an outer limit on duct leakage.

Proposal # 4003
Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code

Revise as follows:

SECTION R403 (IRC N1103) SYSTEMS

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine both total duct leakage and leakage to the outdoors. Air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.

2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Add new text as follows:

R403.3.3.1 (IRC N1103.3.3.1) Total duct leakage rough-in test or post construction test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m2) of conditioned floor area served, (4cfm/100sqft), when the air handler is installed at the time of the test. When the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m2) of conditioned floor area; (3cfm/100sqft). Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. If the HVAC duct work system is serving less than 1500 square feet of conditioned floor area, the allowable total duct leakage target shall be 60 cfm regardless of the calculated 4 cfm/100 sqft minimum performance target.

2. A total duct leakage measurement of 80 cfm or less may replace the requirement to test for duct leakage to outside the building’s thermal envelope (R403.3.3.2) if compliance can be obtained through the modeling software calculations used to verify compliance with Section R405 or Section R406 for duct leakage to outside penalty or tradeoff.

R403.3.3.2 (IRC N1103.3.3.2) Duct leakage to outside the building thermal envelope post construction test. Leakage to outside the building thermal envelope shall be less than or equal to 4 cubic feet minute (113.3 L/min) per 100 square feet (9.29 m2) of conditioned floor area served, (4cfm/100sqft), when tested at a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure, with a blower door and duct leakage testing device. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct leakage to outside test shall not be required where the ducts and air handlers are documented, at a rough stage of construction, to be located entirely within the building’s air barrier and thermal envelope. For systems that are not tested, a distribution systems efficiency of (0.96) for leakage to outside shall be permitted to be used when modeling for confirmed compliance with Sections R405 and R406 for duct leakage to outside penalty or tradeoff.

2. If the HVAC duct work system is serving less than 1500 square feet of conditioned floor area the allowable duct leakage to outside shall be 60 CFM or less.

Revise as follows:

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

...
1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

2. Postconstruction test: Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

Reason:
- Although requiring two duct leakage tests, this proposal actually focuses on total duct leakage. If the total HVAC duct system is tight the built-in exceptions would allow the system not to have the second duct leakage to outside test. In addition, if the duct can be verified to be within the Building’s Thermal Envelope and continuous air barrier assembly the duct would not have to be tested and could you a default distribution system efficiency. In this way great flexibility has been incorporated into this proposal.
- Currently having both mandatory and prescriptive requirements is confusing. Duct leakage testing is needed and needs to just be required to ensure efficiency, durability, safety, and comfort. Just as it is impossible to visually verify if a home’s air barrier system is air tight it is impossible to know if the duct system is tight unless it is tested.
- Both of the current testing paths, prescriptive and mandatory, use the wrong matrix from an energy perspective. In order to ensure the intent of the IECC is maintained regardless of the compliance path, it makes sense to keep the total duct leakage requirement as it deals with the efficiency of the HVAC system from a use perspective. If the master bedroom, for example, is not receiving the quantity of air required by the HVAC design due to leaky ducts, then the thermostat will be adjusted and inefficiencies will be created.
- Adding a Duct leakage to outside (LTO) testing requirement specifically addresses the energy lose component of duct leakage which is also the intent of the IECC. Since duct leakage is associated with two distinct means of inefficiencies, behavior and measured, both tests should be required.
- The 4 cfm/100sqft of floor area target currently penalizes small units, so we have introduced a fix that was first developed by the Energy Star program. Currently the total duct leakage target is based on the amount of conditioned floor area. In this proposal a ‘floor’ has been added to the duct leakage target for small homes. By ‘floor’, we mean a lower limit that doesn’t decrease as the space gets smaller and smaller.
- Energy Stars target floor is 40 CFM. We have used 80 CFM as it is a more reasonable target for small systems in our current state of installation and sealing expertise. In addition, it is our experience that there is a minimal modeling penalty associated with 80 CFM of duct leakage to outside.

Bibliography: Energy Conservatory

Duct Leakage to Outside Testing Instructions

http://energyconservatory.com

Cost Impact: The code change proposal will increase the cost of construction
Currently Total duct leakage testing is required. Duct leakage to outside is also required for IECC code sections R405 simulated performance and R406 ERI pathways. Duct leakage to outside is a tradeable feature and is an input in the modeling software used to demonstrate compliance with the code when using sections R405 and R406. Therefore, the code in essence is currently requiring both tests when these compliance options are used. Price would increase for those who are using the prescriptive path but should remain the same for those using the simulated performance path or the ERI path for compliance.
Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com); Shaunna Mozingo (sdmozingo@shaunnamozingo.com)

2018 International Energy Conservation Code

Revise as follows:

SECTION R403 (IRC N1103)

SYSTEMS

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods - and shall not leak more than 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area served. (4cfm/100sqft), when the air handler is installed at the time of the test. When the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area; (3cfm/100sqft). Registers shall be taped or otherwise sealed during the test.

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.

2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

2. If the HVAC duct system is serving less than or equal to 1,500 square feet of conditioned floor area, the allowable duct leakage shall be 60 cubic feet per minute or less.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Delete without substitution:

R403.3.4 Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

2. Postconstruction test: Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

Reason: Since the 2006 IECC it has been a mandatory requirement to seal ductwork. The language has changed very little and in Section R403.3.2 of the 2018 IECC it now says, “Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.” A separate section is addressing building cavities by stating that, “Building framing cavities shall not be used as ducts or plenums” in order to ensure tight, efficient, and well performing HVAC systems. This short historical perspective reminds us that duct leakage has been an important energy conservation issue for quite some time; at least since 2006. However, it was not until the 2009 IECC that mandatory duct leakage testing entered the code. From that point forward the importance of duct leakage on the efficiency and performance of the house has not change, but more and more confusion has been introduced into the code. Currently, this confusion shows itself primarily in the relationship between testing organizations, HVAC contractors and builders, because there is a requirement to test, but there is no testing threshold target for the performance paths by which to hold a system to. Therefore, when using the performance paths, one mistakenly believes that yes, a system must be tested test, but no it does not have to be tight. This inconsistency between section R403.3.2 Sealing and R403.3.3 Duct testing is at the hart of this code change.

The 4 CFM/100 square feet of conditioned floor area leakage threshold is currently only a prescriptive threshold target. This makes some sense as duct leakage is a tradable performance metric in the software tools used to demonstrate compliance using sections R405 and R406. However, it also makes no sense as the IECC currently requires a total duct leakage test while sections R405 and R406 require a duct leakage to outside test to assess the performance trade off. To add to the confusion, a field testing organization cannot report to the HVAC contractor and builder if a home has passed the duct leakage testing requirements of the code when using performance compliance options because the software tools must be fully
populated with data that is observed at both rough and final stages of construction in order to accurately determine tradeoffs.

This code change proposal simplifies the requirement and enforcement of the requirement. Just as whole house air leakage testing has specific blower door threshold targets, creating one minimum and specific threshold target for duct leakage allows for better and more streamline code adoption and enforcement. From a prescriptive compliance perspective, we know that if the home is equal to or better than the air leakage and duct leakage performance thresholds that it is meeting the minimum efficiency requirements of the code. From a performance perspective we also need to know if the home is meeting the minimum threshold requirements and then additional compliance flexibility is achieved when or if the home performs better. The unintended consequence of introducing a mandatory and prescriptive duct leakage test has only led to mass confusion in the field and a miss interpretation of the requirements.

I believe that the intent of the current 2018 IECC is that the duct leakage testing threshold is the 4% target. However, interpretation abounds. If this proposal is adopted, testing organizations would be able to quickly determine if the home is passing or failing with out argument that tighter systems are not required. Field interpretation from the HVAC contractor and builder side has not been that a specific leakage threshold target must be achieved or that the system must be sealed as Section R403.3.2 Sealing (Mandatory) requires. Instead the field interpretation is often that the system must be tested, but can be extremely leaky. This code change proposal fixes this miss interpretation.

This proposal continues by requiring that the HVAC duct system be tested to a specific minimum target threshold regardless of the location of the duct work. There are two reasons for this change. First, a significant amount of energy savings is achieved when the total leakage of the system is reduced. Remember that the code is currently only testing for total leakage, but only on HVAC systems that have a portion of the duct located outside of the building thermal envelope. When HVAC duct systems are located within the buildings thermal envelop, we are seeing significate total duct leakage that far exceed the 4 CFM/100 square feet of conditioned floor area threshold target, yet the system is in compliance with the code.

BTU's being delivered inside the building's thermal envelop does not equate to a home that is comfortable and efficient unless the correct quantity of BTU's that were designed to be delivered to the specific location occurs. Significant total duct leakage within the thermal envelop by definition ensures that the designed BTU's are not being delivered to their design location therefore causing comfort and efficiency issues. The occupant adjusts the thermostat in an attempt to deliver the required BTU's to the location where they are needed thus casing the system to run more often and less efficiently. The popularity of AaroSeal duct sealing in existing homes is a direct indication of this problem as homeowners seek a solution to leaky inefficient duct work that should have been addressed during construction.

https://aeroseal.com/

https://aeroseal.com/residential/how-aeroseal-works/

https://www.youtube.com/watch?v=06DlipDW0GU

The second reason to require duct leakage testing regardless of where the duct is located is due to cost saving that can be achieved. By just requiring the test to be performed, there will be a move to testing systems at a rough stage of construction to ensure that system testing failures do not impact construction cycle time or the closing of the home. This is the correct stage of construction for conducting the test, as if needed, the system can be economically fixed and retested before drywall has been installed.

Lastly, by holding duct systems to a 4 CFM/100 square feet of conditioned floor area threshold target the likely hood of needing a second test for duct leakage to outside when using R405 and R406 compliance options is low. Total duct leakage numbers in the 4% range can most often be used in software modeling to replace the duct leakage to outside number to demonstrate compliance when duct leakage to outside has not been tested. In other words the HVAC duct system will not leak more to outside than represented by the total duct leakage tested number, so if that number is used to represent duct leakage to outside and the home passes the compliance metrics of sections R405 or R406 then all is good and the home meets the intent of the code.

Cost Impact: The code change proposal will increase the cost of construction

There will be a small cost impact because all duct systems will be required to be tested. However, regardless of where the ducts are located the IECC already requires that the system be sealed in section R403.3.2. It is not possible to visually verified if the duct system is tight just as it is not possible to visually see if a house is air tight, so testing should be required. Energy savings beyond the actual loss of BTU’s to the outside will be achieved, but this will require builders and or HVAC contractors to pay testing organizations or third party approved agencies to verify the duct leakage of the system.
IECC: R403.3.3 (IRC N1103.3.3)

Proponent: Mike Moore, Newport Ventures, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Energy Conservation Code
Revise as follows:

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.

2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators-ventilation systems that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Reason: Regardless of the ventilation system type specified, this section is not meant to verify leakage associated with ventilation systems (exhaust, supply, or balanced/HRV/ERV) that are separate from the ducts serving heating or cooling systems.

Cost Impact: The code change proposal will decrease the cost of construction
This proposal will remove duct leakage verification testing that would otherwise unintentionally be applied to ventilation systems.
RE119-19

IECC: R403.3.3 (IRC N1103.3.4), R403.3.3 (IRC N1103.3.4)

Proponent: Joel Martell, representing National Association of Home Builders (jmartell@nahb.org)

2018 International Energy Conservation Code
Revise as follows:

R403.3.3 (IRC N1103.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer’s air handler enclosure if installed at the time of the test. Registers shall be taped or otherwise sealed during the test.

2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure. Alternatively, a duct leakage test to outside conditioned space with a pressure differential of 0.1 w.g. (25 Pa) with reference to the outside across the entire system including the manufacturer's air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exceptions:

1. A duct air-leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

2. A duct air-leakage test shall not be required for ducts serving heat or energy recovery ventilators that are not integrated with ducts serving heating or cooling systems.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

2. Postconstruction test: Total leakage or leakage to outside conditioned space shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.

Reason: Allowing the option for measurement of duct leakage to the outside will give both HVAC installers and homeowners an accurate measurement of duct leaks to the exterior of the building. This is the only true testing method that measures energy loss as the method is measuring the leakage outside the thermal envelope not from inside conditioned space. Duct leakage to the outdoors is an accepted duct testing method in the industry and was allowed under Section 403.2.2 of the 2009 IECC and approved for the 2015 IECC by the committee, but withdrawn by the proponent. Proposed changes provide clarity as to what distribution system efficiency should be applied to the Standard Reference Design and how the ducts should be modeled in the performance path.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
This proposal will not change the cost of construction. It will provide a testing method that measures the true energy loss of ducts.
RE120-19
IECC: R403.3.4 (IRC N1103.3.4)

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Gutman, BCAP-IBTS, representing BCAP-IBTS (mgutman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code
Revise as follows:

R403.3.4 (IRC N1103.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4.0 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m\(^2\)) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3.0 cubic feet per minute (85 L/min) per 100 square feet (9.29 m\(^2\)) of conditioned floor area.
2. Postconstruction test: Total leakage shall be less than or equal to 4.0 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m\(^2\)) of conditioned floor area.

Reason: The purpose of this code change proposal is to clarify the current requirements for maximum duct leakage that are already part of the IECC and to ensure that buildings achieve the efficiency intended by the code by adding an additional digit. Specifically, the code proposal adds ".0" to the specified duct leakage rate to clarify that a value above 4.0 cfm (or 3.0 cfm where the air handler is not installed) is not allowed. While we believe that the best interpretation of the current standard is that the duct leakage may not exceed 4.0, the addition of another digit will pre-empt any claim that a tested value above these maximums, such as 4.4, will meet the maximum. By preempting these "round off" arguments from code users, this change will provide additional support for building code officials who are simply trying to enforce the code. This proposed clarification will not change any substantive requirements of the code but will improve compliance and enforcement and eliminate any confusion.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. It merely serves to clarify a current requirement to avoid confusion and inconsistent enforcement.

Proposal # 3965
2018 International Energy Conservation Code

Add new text as follows:

**R403.3.4.1 (IRC N1103.3.4.1) Sampling options for R2 multifamily dwelling units.** For buildings having three or more dwelling units, a minimum of 15% of the dwelling units in each building must be tested as required by Section R403.3.3. Prior to beginning sampling for testing, “Initial Testing” is required for each multifamily property. “Initial Testing” shall consist of the 3rd party testing contractor performing the required tests on at least three consecutive dwelling units. Test results from the “Initial Testing” must satisfy minimum code requirements before sampling is permitted. Dwelling units selected for the “Initial Testing” must be within the same building. Dwelling units selected for “Initial Testing” shall not be included in a “sample group” or counted toward the minimum 15% of dwelling units tested. The building official shall randomly select the three dwelling units for “Initial Testing.” The building official may delegate the random selection to the designated 3rd party testing contractor.

**R403.3.4.1.1 (IRC N1103.3.4.1.1) Sample group Identification and Sampling** The builder shall identify a “sample group” which may be a building, floor, fire area or portion thereof. All of the dwelling units within the “sample group” must be at the same stage of construction and must be ready for testing. The building official shall randomly select at least 15% of dwelling units from each “sample group” for testing. The building official may delegate the random selection to the designated 3rd party testing contractor. If each tested dwelling unit within a “sample group” meets the minimum code requirements, then all dwelling units in the “sample group” are considered to meet the minimum code requirements.

Before a building may be deemed compliant with the testing as required, each “sample group” must be deemed compliant with the minimum code requirements. The sum total of all of the tested dwelling units across all “sample groups” shall not be less than a minimum of 15% of the dwelling units in a building.

**R403.3.4.1.2 (IRC N1103.3.4.1.2) Failure to Meet Code Requirement(s).** If any dwelling units within the identified “sample group” fail to meet a code requirement as determined by testing, the builder will be directed to correct the cause(s) of failure, and 30% of the remaining dwelling units in the “sample group” will be randomly selected for testing by the building official, or third-party testing contractor, regarding the specific cause(s) of failure. If any failures occur in the additional dwelling units, all remaining dwelling units in the sample group must be individually tested for code compliance.

A multifamily property with three failures within a 90-day period is no longer eligible to use the sampling protocol in that community or project until successfully repeating “Initial Testing.” Sampling may be reinstated after at least three consecutive dwelling units are individually verified to meet all code requirements.

A Certificate of Occupancy may not be issued for any building until testing has been performed and deemed to satisfy the minimum code requirements on the dwelling unit(s) identified for testing.

**Reason:** For many multifamily (R2 classifications) projects, it is very costly and time consuming to test each dwelling unit for projects where there may be dozens of dwelling units in each building. Considering that the same tradesman generally constructs a building, it is reasonable to deem that construction practices are consistent and that if a reasonable sampling of units tested pass then all units would pass. These amendments (originally drafted by the North Texas Council of Governments Energy and Green Advisory Board) or are very similar ordinances, have been accepted across Texas by the EHJs including the City of Dallas, the City of Austin, and the City of San Antonio.

**Cost Impact:** The code change proposal will decrease the cost of construction

This code change proposal will streamline the cost and time required to conduct on-site verification of Code which will result in lower testing costs and faster construction timelines
RE122-19
IECC: R403.3.6.1 (IRC N1103.3.6.1)

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code
Revise as follows:

R403.3.6.1 (IRC N1103.3.6.1) Effective R-value of deeply buried ducts (Mandatory). Where using a simulated energy performance analysis, sections of ducts that are: installed in accordance with Section R403.3.6; located directly on, or within 5.5 inches (140 mm) of the ceiling; surrounded with blown-in attic insulation having an R-value of R-30 or greater and located such that the top of the duct is not less than 3.5 inches (89 mm) below the top of the insulation, shall be considered as having an effective duct insulation R-value of R-25.

Reason: This section provides to installation details related to a calculation methodology to be used in specific circumstances. There is no value or metric available for trade-offs in the performance path.

As such SEHPCAC believes this is a mandated, non-tradeable methodology for calculating R-value, and should be labeled mandatory.

Note that the SEHPCAC has a proposal to eliminate the use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This does not change the design or construction requirements it makes mandatory the standard R-value calculation methodology

Proposal # 4480
IECC: R403.4.1 (IRC N1103.4.1)

Proponent: Howard Ahern, representing self (howard.ahern@airexmfg.com)

2018 International Energy Conservation Code

Revise as follows:

R403.4.1 (IRC N1103.4.1) Protection of piping insulation (Mandatory). Piping insulation exposed to weather shall be protected from damage, including that caused by sunlight, moisture, equipment maintenance and wind. The protection shall provide shielding from solar radiation that can cause degradation of the material. Adhesive tape shall be prohibited.

Reason: The protection of pipe insulation should be a Mandatory requirement just as the requirement to insulate pipes of the heating or cooling system. As the commercial IECC requires protection as mandatory this residential, section needs to as well. Energy saving for insulating piping of heating and cooling systems is well researched and documented. Protecting this energy saving is crucial.

Example of saving from protecting the insulation can be measured in Dr Kourmohammadi PE, Ph.D. CPD, CIPE, CFPE LEED AP

"Insulation materials cannot endure physical impact or are fragile to many elements, i.e. weather. Weather impact on insulation is very high. The sun enhances the transforms the insulation from thermoplastic (soft) foam to thermoset (brittle) foam property. The property change also impacts the thermal conductivity of the material and consequently its performance. Protective covers become the sacrificial lamb and provide the stability in properties of the insulation.

Maintenance of pipes insulation is often non-existence. Aged insulation is generally brittle, poorly reinstalled, and subject to damage to the weather."

Paper on Protective covers which calculated the BTU and Electrical energy saving of exposed Freon lines for residential and multifamily purposes.

Freon lines exposed 3 ft to 5 ft

0.15/kwhr cost of electricity (peak demand cost can be at

0.25$/kwhr)

10 hours operation

365 days

¾" Freon line

¹⁄₂" insulation property 0.020227 Btu/(hr F ft)

For the California region it amounted to a $1.00 per foot annual savings

Example of cost saving average 5ft per unit in California with a population of 39 million and

If only half of the population for example had a heating and Cooling system with an average of 5ft exposed piping with degraded or no insulation, Protected pipe insulation would amount to an yearly electrical saving of $975,000,000

This is electrical saving and does not include the saving to home and building owners from not having a costly expenses of replacing insulation for maintenance
Bibliography: Impact and Advantages of Removable Insulation Protective Covers

Dr. “Saum” K. Nourmohammadi, PEx3, Ph.D. CPD, CIPE, CFPE, LEED AP

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change will not increase the cost of construction as protection is required by this section and by pipe insulation manufactures.
**RE124-19**

IECC: R403.3.5 (IRC N1103.3.5)

**Proponent:** Ron Clements, Chesterfield County, representing Chesterfield County (clementsro@chesterfield.gov)

**2018 International Energy Conservation Code**

Delete without substitution:

**R403.3.5 Building cavities (Mandatory).** Building framing cavities shall not be used as ducts or plenums.

**Reason:** Duct system construction methods and materials is outside the scope of IRC chapter 11. Duct system construction is within the scope of IRC chapter 16. Section M1601.1.1 #7 allows the use of stud wall cavities for return air. This is a code correlation issue. If stud cavities should not be used under any circumstance then M1601.1.1 should be amended.

**Cost Impact:** The code change proposal will decrease the cost of construction

If approved this code change will allow use of wall cavity spaces as return duct plenums, which saves money that would need to be spent on return duct work.

Proposal # 5613
2018 International Energy Conservation Code

Revise as follows:

R403.5.2 (IRC N1103.5.2) Demand recirculation water systems (Mandatory). Where installed, demand recirculation water systems shall have controls that comply with both of the following:

1. The controls shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The controls shall limit the temperature of the water entering the cold water piping to not greater than 104°F (40°C).

Reason: There are no values or metrics for energy performance associated with Sec. R403.5.2. This means there is no value that can be used for trade-offs in the performance path. Because the provisions of R403.5.2 cannot be feasibly modeled or traded they should be labeled as mandatory.

The words "where installed" were added to make clear that Demand Recirculation Systems themselves are not required to be installed, but that where they are installed there is no value in trading the provisions in the performance path.

Note that the SEHPCAC has a proposal to eliminate the use of the labels "prescriptive" and "mandatory" in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as 'mandatory' will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will increase the cost of construction

The code change may increase construction costs for a subset of buildings that may have been designed using the Total Building Performance or EIR compliance methods that included Demand recirculation water systems without the specified controls.
RE126-19

IECC: R202 (IRC N1101.6), R403.5.1 [IRC N1103.5.1] (New), TABLE R403.5.1 [IRC N1103.5.1] (New)

Proponent: Lauren Urbanek, representing Natural Resources Defense Council (lurbanek@nrdc.org)

2018 International Energy Conservation Code

Add new text as follows:

R403.5.1 (IRC N1103.5.1) Water heating equipment. Service water heating equipment shall be one or more of the following types:

1. Storage gas water heater with a uniform energy factor (UEF) that meets the requirements of Table R403.5.1.
2. Storage electric water heater utilizing not less than 1.0 kW of on-site renewable energy.
3. Heat pump water heater with a UEF not less than of 2.0.
4. Tankless water heater.
5. Grid-enabled water heater.
6. Solar water heating system having a solar fraction of not less than 0.5.

a. The first hour rating of a water heater is determined by the federal test procedure. It is listed on the Energy Guide label affixed to the water heater.

SECTION R202 (N1101.6)

GENERAL DEFINITIONS

Add new definition as follows:

GRID-ENABLED WATER HEATER. An electric water heater that includes controls that enable activation for use as part of an electric thermal storage or demand response program.

SOLAR FRACTION. The fraction of total annual water heating energy met by a solar water heater.

Reason: This proposal improves the energy efficiency of the prescriptive path of the code while continuing to offer builders the same level of flexibility they already enjoy. Builders may still install any type of water heater that works for the home and location, including storage gas or electric water heaters. While it is true that not every home may be able to utilize every option listed, there is an option that is appropriate for any home. This proposal also modifies only the prescriptive path, which leaves builders the flexibility of the performance and ERI paths. This proposal is structured so that it does not trigger provisions of the National Appliance Energy Conservation Act (NAECA). See attached for a legal memorandum.

Residential envelopes have been getting tighter and better over the last few years. As a result, domestic water heating energy is emerging as a significant end-use from the efficiency stand-point. There are multiple ways of improving the efficiency of generating hot water in homes.

The US Department of Energy’s analysis for the standard that took effect in 2015 found that high-efficiency gas storage water heaters cost less upfront to install in new construction than standard efficiency models, due to lower venting costs of the high-efficiency equipment[1]. Furthermore, this efficiency level is cost-effective for customers compared to a standard model, saving more than $200 in energy costs. This means that customers will save money on their bills by installing a more efficient gas storage water heater and will pay less to purchase the efficient model than the less-efficient model. Gas furnaces that meet the Uniform Energy Factors specified in this proposal are widely available. Uniform Energy Factors are specified, per the DOE federal test procedure, based on the equipment’s First Hour Rating, which is clearly labeled on the yellow Energy Guide label affixed to each

Storage electric water heaters may be installed, when coupled with solar energy. The purpose of this requirement is to offset the electricity used to heat the water, saving money for the consumer. In addition, solar energy is a strong selling point for a new home.

DOE analysis found that heat pump water heaters that replace electric storage water heaters are wildly cost-effective in all climate zones, in spite of their higher equipment costs. Homeowners will save more than $500 in energy costs compared to even an efficient electric storage water heater.
Tankless water heaters were cost-effective in the warmer climate zones, but were not as cost-effective in the colder climate zones.

As part of DOE’s appliance and equipment standards initiative, stakeholders expressed the importance of electric resistance water heaters to electric thermal storage (ETS) programs, so those grid-enabled water heaters are also incorporated into this proposal. Utilities use ETS programs, sometimes also known as load shifting or demand response programs, to manage peak demand load by limiting the times when certain appliances are operated. In certain water-heater based ETS programs, a utility typically controls a water heater remotely to allow operation only when electricity demand is during off-peak hours. During that off-peak operation, the electricity consumed is stored by the water heater as thermal energy for use during peak hours when the utility prevents the water heater from using electricity.

A solar water heating system can be designed in a variety of different ways. They can directly heat the water using the sun, can indirectly transfer heat from the sun to water in a storage tank, or can use pumps and valves to move water from collectors to a storage tank. They can have either gas or electric backup heating capabilities. This proposal requires at least half of the total energy delivered to the water heater to be generated through solar energy.

LEGAL MEMORANDUM CONCERNING NRDC’S PROPOSED R403.5.1 AND THE
NATIONAL APPLIANCE ENERGY CONSERVATION ACT

Introduction

The Natural Resources Defense Council (NRDC) proposes the addition of R403.5.1 to Chapter 4 of the 2018 International Efficiency Conservation Code (IECC). The proposed addition prescribes six types of water heaters which may be installed by builders in order to comply with the prescriptive compliance pathway of IECC Chapter 4. Some commenters on similar past proposals expressed concern that such a provision would be preempted by the National Appliance Energy Conservation Act, which amended the Energy Policy Conservation Act and set up the energy efficiency standards program for appliances, including water heaters. This is not the case. The proposed code addition comports with the federal statutory provision for building codes because it does not require installation of water heaters that exceed the current federal minimum level.

Legal Analysis

As explained in greater detail below, the issue is whether these proposed additions would effectively require builders to use products that are more efficient than required by federal efficiency standards and thus would trigger preemption. Because they do not there is no preemption concern here.

The National Appliance Energy Conservation Act provides that state building codes may include provisions concerning the efficiency of appliances covered by federal efficiency standards if they meet seven specified requirements. Commenters in the past expressed concern that the provision would not meet two of these requirements: Sections 6297(f)(3)(B) and 6297(f)(3)(E). The basic requirement of these two provisions is that the building code not require use of an appliance more efficient than the level set by the Department of Energy under the Act.

The first of these focuses on the code as a whole. It states, in relevant part, that the code may not “require that the covered product have an energy exceeding the applicable energy conservation standard…” The second provision concerns building codes that offer optional combinations of items. Our proposed changes easily satisfy this provision because, as discussed below,

1 This memorandum is submitted as an attachment to NRDC’s July 21, 2016 proposed amendment.
2 42 U.S.C. § 6297(f)(3);
3 It is not clear whether the optional “combinations of items” applies to the prescriptive pathway at all.
4 42 U.S.C. § 6297(f)(3)(E). Assuming that it does, we believe the relevant “combinations” would be the combination of each of the different water heater options and the rest of the prescriptive options. The proposed standard avoids preemption because it includes multiple optional combinations that include minimum efficiency water heaters and only two that require higher efficiency appliances.
four of the six options do not involve products that exceed existing federal standards. (A fifth option may not require a standard-exceeding product depending on the first hour rating of the water heater.)

The presence of some more efficient options does not trigger preemption. In interpreting these provisions, the Ninth Circuit Court of Appeals has recognized that “a builder is not required to select a [more efficient] option . . . simply because there is an economic incentive to do so.”

The proposed amendment would be not preempted because it allows installation in new residential buildings of minimum-efficiency water heaters. The statutory preemption test focuses on the “covered product,” which is defined in this case as water heaters. Thus, a building code is not preempted so long as it does not require installation of a covered product—in this case a water heater—that is above the minimum efficiency level. The proposed amendment plainly does not do so for several reasons. First, the performance path (Section 405) and the Energy Rating Index path (Section 406) focus on overall energy use and include no water heater requirements at all.

Second, even just considering the prescriptive pathway, the proposed amendment still does not require use of a water heater that exceeds minimum federal standards. The proposed amendment allows builders to select any of the six prescribed types of water heaters, at least two of which clearly do not exceed the federal requirements: tankless water heaters (R403.5.1.4) and grid-enabled water heaters (R403.5.1.5). For tankless water heaters, the proposed code amendment contains no minimum efficiency standard and thus the federal standards would apply. For grid-enabled water heaters, the proposed code complies with the federal provision. As such, builders can comply with the standard by using water heaters that meet, but do not exceed, federal efficiency standards. Indeed, even if these minimum efficiency options were not available, the prescriptive path would still not “require” use of higher efficiency water heaters since any type of water heater can be used under the prescriptive approach if combined with other options such as a solar water heater.

The proposed amendment is also similar to existing building code provisions. The prescriptive compliance path in California’s 2016 building code, for instance, requires installation of either gas/propane instantaneous water heaters or gas/propane storage type water heaters in new residential dwellings. California’s prescriptive compliance path allows use of certain minimum efficiency water heaters but does not allow use of every type of minimum efficiency water heater. Like the proposed

---

7 Id.
8 See Building Industry Ass’n of Wash., 683 F.3d at 1151.
code, the California code allows builders to choose an alternate compliance path, which allows use of any water heater.19

**Conclusion**

The core requirement for a building code to avoid preemption is that it not require above-minimum efficiency appliances. This requirement is met by the NRDC proposal because the proposal offers multiple ways that minimum efficiency water heaters can be used under both the prescriptive and performance pathways.

---

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal provides a list of options for a builder to choose from. In some instances the builder may choose an option which increases construction costs, but there are many options that will not increase costs. For instance, the US Department of Energy’s analysis for the water
heater standard that took effect in 2015 found that high-efficiency gas storage water heaters cost less upfront to install in new construction than standard efficiency models, due to lower venting costs of the high-efficiency equipment.
RE127-19
IECC: R403.5.3 (IRC N1103.5.3)

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R403.5.3 (IRC N1103.5.3) Hot water pipe insulation (Prescriptive). Insulation for service hot water piping with a thermal resistance, $R$-value, of not less than $R$-3 shall be applied to the following:

1. Piping 3/4 inch (19.1 mm) and larger in nominal diameter located inside the conditioned space.
2. Piping serving more than one dwelling unit.
3. Piping located outside the conditioned space.
4. Piping from the water heater to a distribution manifold.
5. Piping located under a floor slab.
7. Supply and return piping in circulation and recirculation systems other than cold water pipe return demand recirculation systems.

Reason: The change clarifies the intent of the requirements which require all piping in items 2 through 7 to be insulated regardless of pipe diameter. The exemption in item 7 is further clarified by not requiring insulation on the "cold water pipe return" in a demand recirculation system.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a clarification only, not an additional design or construction requirement.

Proposal # 4759
2018 International Energy Conservation Code

Revise as follows:

R403.5.3 (IRC N1103.5.3) Hot water pipe insulation (Prescriptive Mandatory). Insulation for hot water piping with a thermal resistance, $R$-value, of not less than $R$-3 shall be applied to the following:

1. Piping $\frac{3}{4}$ inch (19.1 mm) and larger in nominal diameter.
2. Piping serving more than one dwelling unit.
3. Piping located outside the conditioned space.
4. Piping from the water heater to a distribution manifold.
5. Piping located under a floor slab.
7. Supply and return piping in recirculation systems other than demand recirculation systems.

Reason: Because the provisions of R403.5.3 cannot be feasibly modeled or traded; and because of there is no design reason to attempt to model it, R403.5.3 should be labeled as mandatory.

Note that the SEHPCAC has a proposal to eliminate the use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will increase the cost of construction

Although SEHPCAC has been assured pipe insulation is industry practice, this code change may increase construction costs for a subset of buildings that were not insulating pipes.
IECC: R403.5.4 (IRC N1103.5.4)

Proponent: David Collins, SEHPCAC, representing SEHPCAC (SEHPCAC@iccsafe.org); David Collins, representing The American Institute of Architects (dcollins@preview-group.com)

2018 International Energy Conservation Code

Revise as follows:

R403.5.4 (IRC N1103.5.4) Drain water heat recovery units (Mandatory). Drain water heat recovery units shall comply with CSA B55.2. Drain water heat recovery units shall be tested in accordance with CSA B55.1. Potable water-side pressure loss of drain water heat recovery units shall be less than 3 psi (20.7 kPa) for individual units connected to one or two showers. Potable water-side pressure loss of drain water heat recovery units shall be less than 2 psi (13.8 kPa) for individual units connected to three or more showers.

Reason: Because the provisions of R403.5.4 cannot be feasibly modeled or traded; and because of there is no design reason to attempt to model it, R403.5.4 should be labeled as mandatory (non-tradeable). Note that the SEHPCAC has a proposal to eliminate the use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved to be labeled as ‘mandatory’ will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

Cost Impact: The code change proposal will increase the cost of construction. Although SEHPCAC has been assured this is standard industry practice, the code change may increase construction costs for a subset of buildings that may have been designed to include drain water heat recovery but not in accordance with the specified standard.

Proposal # 4487
IECC: R403.6.2 (IRC N1103.6.2)  (New)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robby@nrglogic.com)

2018 International Energy Conservation Code
Add new text as follows:

R403.6.2 (IRC N1103.6.2) Testing. Mechanical ventilation systems shall be tested and verified to provide the minimum ventilation flow rates required by Section R403.6. Testing shall be performed according to the ventilation equipment manufacturer’s instructions, or by using a flow hood or box, flow grid, or other airflow measuring device at the mechanical ventilation fan’s inlet terminals or grilles, outlet terminals or grilles, or in the connected ventilation ducts. Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Exception: Kitchen range hoods that are ducted to the outside with 6” or larger duct and one or less 90° elbow or equivalent in the duct run are exempt from this requirement to test air flow.

Reason: As we continue to be guided by sound building science to build tight homes as required by the IECC to achieve better predictability and control of air flow, thermal flow, and moisture flow spot/local and whole house ventilation becomes an even more crucial aspect of ensuring that the full intent of the IECC is met. This includes durability, safety, healthy, flexibility in how we build, as well as, efficiency of the structure. If we do not more actively ensure that the systems in our homes are not only there, but are also performing as intended we have missed the mark with regards to the intent of the code and creating dwellings that are durable, safe, healthy, and efficient. The testing experience gained through the verification of the EnergyStar program has clearly demonstrated that ventilation fans are installed but are not performing as required by the code. Fan rated flow does not equate to the flow that is actually produced once a fan has been installed. The quality of the installation of the duct from the fan to the termination of the duct to the outside, as well as, the quality of the termination device ultimately governs the amount of air that any fan can push. Simple cost-effective testing is available to ensure that the systems in our homes are not only there but have been installed in such a way that they work as intended by the code.

Allison Bailes Energy Vanguard blog post titled, “The 2 Main Problems With Kitchen Ventilation” which can be found here https://www.energyvanguard.com/blog/2-main-problems-kitchen-ventilation Offers additional rational regarding the consequences of poor ventilation from research conducted by Brett Singer and others at Lawrence Berkeley Laboratory. If you are interested there are additional links at the end of his post to related articles that further discuss this issue. I offer this background information to demonstrate that beyond the physical failure of measured fan flow to meet the requirements of code, that there is an extensive study being produced on the effects of improper ventilation. Requiring testing of spot/local and whole house ventilation system will move the building industry into compliance with the code by offering direct feedback on the fan choice and the installation. In the most flexible way possible this feedback will guide fan choice and installation techniques that will become compliant with the code.

Cost Impact: The code change proposal will increase the cost of construction

The cost implications of this code change are small. Qualified testing personnel are already available and at the building performing blower door and duct leakage tests. Adding simple flow measurements of ventilation systems at the same time a blower door test occurs, for example, is not only practical but cost-effective. An increase is cost of $25-$50 is well worth the reduction in builder risk, occupant health, and efficiency issues that are associated with poor implementation of code required moisture and pollutant management.
Add new text as follows:

**R403.6 (IRC N1103.6) Mechanical Ventilation (Mandatory).** The building shall be provided with ventilation that meets the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

**R403.6.1 (IRC N1103.6.1) Heat recovery ventilation (Prescriptive).** The building shall be provided with a heat recovery or energy recovery ventilation system in climate zones 7 and 8. The system shall be balanced with a minimum sensible heat recovery efficiency of 65% at 32°F (0°C) and at rated airflow.

Revised as follows:

**R403.6.1 (IRC N1103.6.1) R403.6.1.2 (IRC N1103.6.1.2) Whole-house mechanical ventilation system fan efficacy.** Fans used to provide whole-house mechanical ventilation shall meet the efficacy requirements of Table R403.6.1.

**Exception:** Where an air handler that is integral to tested and listed HVAC equipment is used to provide whole-house mechanical ventilation, the air handler shall be powered by an electronically commutated motor.

**Reason:** How does the proposed measure compare to what's required in current codes? The national model energy code for residential buildings, the International Energy Conservation Code (IECC), does not require heat recovery ventilation, though it does establish minimum efficacy ratings for HRV fans if a home has one. All new homes are currently required to have mechanical ventilation based on the International Residential Code (IRC), with continuous fresh air requirements ranging from 30 to 165 CFM depending on the home's conditioned floor area and number of bedrooms. For dwelling units between 1200 ft² and 4500 ft², with two to four bedrooms, the range is 45 to 90 CFM.

Why is heat recovery a better approach to ventilation than alternatives?

In years past, the overall leakiness of building envelopes provided sufficient fresh air for occupants, but brought with it substantial energy penalties and comfort issues from widely varying ventilation rates depending on outdoor temperature and wind speed. As construction practices have gained better control of envelope leakage, mechanical ventilation systems have become a necessity and are required by modern building codes. In sufficiently cold climates, heat recovery can enhance comfort—as occupants are not subjected to uncomfortably cold supply air—and may be cost effective in their recovery of heat that would otherwise be exhausted.

HRVs have experienced significant growth in the residential market in recent years. This market is projected to continue growing at 11% per year per MarketsandMarkets (2018). North America is the largest market in the world for HRVs.

ERVs are not considered in this paper because their performance and cost effectiveness is more dependent on local humidity and on the interplay of heating and cooling performance. These factors do not map as cleanly to the high-level climate zones typically used in state and local building energy codes.

How is system performance demonstrated in the field?

HRVs come in several forms, ranging from systems integrated into the HVAC distribution system, to separate systems with their own ductwork, to simple unducted heat exchangers. System performance is easy to verify based on the unit’s nameplate performance ratings and straightforward inspection of the installation.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The cost of HRV equipment ranges from about $500 to a few thousand dollars, depending on the manufacturer, capacity, configuration, and the base design of the home. The present analysis assumes a total measure cost of $1,500 for a single-point HRV system. NREL (2018) gives a cost of $1,300, inclusive of equipment and installation. Russell, Sherman and Rudd (2007) found a similar cost of $1,350 including installation. Fixr.com (2018), a home remodeling website, gives a range of $1,200 to $1,550, inclusive of materials and installation. Moore (2018) suggests a typical cost of $1,500. This analysis uses a primary first cost of $1,500 for an HRV in a typical dwelling unit as a best estimate that includes installation. It is acknowledged that real costs can vary greatly, especially if the cost of installation is minimized, as when the home was already designed to integrate ventilation into the distribution system. In that case, the HRV cost can be quite low. To show the sensitivity of HRV cost effectiveness to first cost, a secondary cost of $500 was evaluated in addition to the primary cost of $1,500.

Cost-effectiveness: At a first cost of $1,500, the life-cycle cost of an HRV is negative (i.e., life-cycle savings is positive) in climate zones 7 and 8, as shown in Table 2 of the attached PNL Residential Heat Recovery Ventilation Technical Brief.
RE132-19 Part I

PART I — IECC: R403.6 (IRC N1103.6)

PART II — IRC®: R303.4

Proponent: Mike Moore, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Energy Conservation Code

Revise as follows:

R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory). The building Buildings and dwelling units shall be provided with mechanical ventilation that complies with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.
RE132-19 Part II
IRC®: R303.4

Proponent: Mike Moore, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Residential Code
Revise as follows:

R303.4 Mechanical ventilation. Where the air infiltration rate of a dwelling unit is 5 air changes per hour or less where tested with a blower door at a pressure of 0.2 inch w.c. (50 Pa) in accordance with Section N1102.4.1.2, the dwelling unit Dwelling units complying with Section N1102.4.1 shall be provided with whole-house mechanical ventilation in accordance with Section M1505.4.

Reason: Changes to R303.4
Section N1102.4 establishes MANDATORY requirements for air sealing of the building envelope, including mandatory requirements to follow the air barrier and insulation installation criteria in Table N1102.4.1.1 and the mandatory blower door testing and verification requirements in Section N1102.4.1.2. Further, all dwelling units complying with Section N1102.4 require a blower door test with results that achieve 5 ACH50 or less. Thus, all dwelling units complying with Section N1102.4 already require whole-house mechanical ventilation. This change simplifies Section R303.4 and future-proofs the intent of the section by ensuring that tight dwelling units will continue to be provided with whole-house mechanical ventilation, regardless of the metric used to verify that the dwelling units are tight (e.g. there are several proposals being heard in Group B that would move from the metric of ACH50 to a metric of cfm50/ft2).

These changes are aligned with Group A action on proposal M20. M20 was approved and removed the specific reference to 5 ACH50 as the air leakage metric that triggers a mechanical ventilation requirement in Section 401.2 of the IMC as follows:

401.2 Ventilation required. Every occupied space shall be ventilated by natural means in accordance with Section 402 or by mechanical means in accordance with Section 403. <Strikeout the following text: Where the air infiltration rate in a dwelling unit is less than 5 air changes per hour when tested with a blower door at a pressure of 0.2-inch water column (50 Pa) in accordance with Section R402.4.1.2 of the International Energy Conservation Code, the dwelling unit shall be ventilated by ... End strikeout section > Dwelling units complying with the air leakage requirements of the International Energy Conservation Code or ASHRAE 90.1 shall be ventilated by mechanical means in accordance with Section 403.

Changes to Section 403.6

In keeping with IRC Section R303.4 and IMC Section 401.2, the heading of section 403.6 requires “mechanical” ventilation for buildings complying with the IECC-Residential. To clarify that this is the intent of this section and is coordinated with the IRC and IMC (which contain mechanical ventilation requirements for buildings and dwelling units), the words “mechanical” and “dwelling units” are proposed for inclusion within the text of R403.6.

These changes are aligned with Group A action on proposal M20. M20 was approved and removed the specific reference to 5 ACH50 as the air leakage metric that triggers a mechanical ventilation requirement in Section 401.2 of the IMC as follows:

401.2 Ventilation required. Every occupied space shall be ventilated by natural means in accordance with Section 402 or by mechanical means in accordance with Section 403. <Strikeout the following text: Where the air infiltration rate in a dwelling unit is less than 5 air changes per hour when tested with a blower door at a pressure of 0.2-inch water column (50 Pa) in accordance with Section R402.4.1.2 of the International Energy Conservation Code, the dwelling unit shall be ventilated by ... End strikeout section > Dwelling units complying with the air leakage requirements of the International Energy Conservation Code or ASHRAE 90.1 shall be ventilated by mechanical means in accordance with Section 403.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal is a clarification of current requirements of the IRC, IMC, and IECC and does not increase or decrease the cost of construction.

Proposal # 5696
2018 International Energy Conservation Code

Revise as follows:

### TABLE R403.6.1 (IRC N1103.6.1)

WHOLE-HOUSE MECHANICAL VENTILATION SYSTEM FAN EFFICACY^a^  

<table>
<thead>
<tr>
<th>FAN LOCATION</th>
<th>AIR FLOW RATE MINIMUM(CFM)</th>
<th>MINIMUM EFFICACY(CFM/WATT)</th>
<th>AIR FLOW RATE MAXIMUM(CFM)</th>
</tr>
</thead>
<tbody>
<tr>
<td>HRV or ERV</td>
<td>Any</td>
<td>1.2 cfm/watt</td>
<td>Any</td>
</tr>
<tr>
<td>Range hoods</td>
<td>Any</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
<tr>
<td>In-line fan</td>
<td>Any</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
<tr>
<td>Bathroom, utility room</td>
<td>10</td>
<td>2.8 cfm/watt</td>
<td>&lt; 90</td>
</tr>
<tr>
<td>Bathroom, utility room</td>
<td>90</td>
<td>3.5 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916.

**Reason:** Whole-house ventilation fan efficacies were introduced in the code in 2012 for low-rise residential buildings and have not been updated since. The current residential fan efficacies are from an older version of Energy Star. This proposal will update the requirements to the latest Energy Star requirement Version 4.0. The fan efficacy values are very conservative based on what is currently on the market. Although they are substantially better than current requirements, they are still lower than the average efficiency of fans in the Home Ventilating Institute's fan database. These requirements are below the average efficiency for each fan type on the market, but higher than the standard set in the residential code. For example, according to the HVI database of fans, the average efficiency of bath fans is around 8 CFM/W.

A proposal has also been submitted to add similar requirements for similar low-capacity fans in the commercial section of the code.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal is not expected to increase the cost of construction. Cost for the kinds of fans covered by this requirement are driven primarily by flow rate, finishes, design and noise and whether they include other features like lights or heaters and not efficiency. Fans that meet this requirement can be obtained for less than other fans that do not. A survey of pricing from a major retailer revealed that the lowest cost bathroom fans from major manufacturers that currently comply with Table R403.6.1 would also comply with the proposed increase in efficacy, resulting in no cost increase.

Lowest cost exhaust fans for major manufacturers meeting current IECC fan efficacy requirement at 0.1” w.c. and IRC flow rate requirement at 0.25” w.c, flow < 90 cfm:

<table>
<thead>
<tr>
<th>Fan</th>
<th>Efficacy at 0.1” w.c.</th>
<th>Flow at 0.25” w.c.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AirKing BFQ75</td>
<td>3.0</td>
<td>70</td>
</tr>
<tr>
<td>DeltaBreeze SLM70</td>
<td>4.7</td>
<td>54</td>
</tr>
<tr>
<td>Broan AE80B</td>
<td>3.0</td>
<td>60</td>
</tr>
</tbody>
</table>

Pricing for these fans ranged between $35-$53 retail. Note that the fan efficacy for each of these lowest-cost fans that are currently compliant with the IECC and IRC would also comply with the proposed revision in fan efficacy to 2.8 cfm/W, so there is no additional cost.

Lowest cost exhaust fans for major manufacturers meeting current IECC fan efficacy requirement at 0.1” w.c. and IRC flow rate requirement at 0.25” w.c, flow > 90 cfm:

<table>
<thead>
<tr>
<th>Fan</th>
<th>Efficacy at 0.1” w.c.</th>
<th>Flow at 0.25” w.c.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AirKing AK110LS</td>
<td>3.9</td>
<td>90</td>
</tr>
<tr>
<td>DeltaBreeze VFB25AEH</td>
<td>5.9</td>
<td>105</td>
</tr>
</tbody>
</table>
Pricing for these fans ranged between $89-$105 retail. Note that the fan efficacy for each of these lowest-cost fans that are currently compliant with the IECC and IRC would also comply with the proposed revision in fan efficacy to 3.5 cfm/W, so there is no additional cost.

RE134-19
IECC: R403.6.1 (IRC N1103.6.1), TABLE R403.6.1 (IRC N1103.6.1)

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code
Revise as follows:

R403.6.1 (IRC N1103.6.1) Whole-house Whole-dwelling mechanical ventilation system fan efficacy. Fans used to provide whole-house mechanical ventilation shall meet the efficacy requirements of Table R403.6.1.

**Exception:** Where an air handler that is integral to tested and listed HVAC equipment is used to provide whole house mechanical ventilation, the air handler shall be powered by an electronically commutated motor.

<table>
<thead>
<tr>
<th>FAN LOCATION</th>

<tr>
<td>Air-handler that is integrated to tested and listed HVAC equipment</td>
<td>Any</td>
<td>1.2 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916.
b. Design outdoor airflow rate / watts of fan used

**Reason:** Typical integrated whole-dwelling mechanical ventilation systems, even those that are using ECM motors, use significantly more energy than the other fan locations allowed under R403.6.1. Analyses using ERI approved software calculate the increase in annual energy usage for an integrated whole-dwelling mechanical ventilation system to be up to 10x when compared to an independent in-line fan. As such requiring integrated mechanical ventilation system to perform equally to at least the most energy inefficient of the other styles of systems in this table could result in significant energy savings.

Footnote b. clarifies how the CFM/watt should be calculated by specifying that the CFM of Outdoor mechanical ventilation air should be used for this calculation and not the total airflow of the system delivering the air. Some ventilation systems use a single fan to deliver mixed outdoor and with indoor “return” air. For this calculation only the outdoor airflow should be used in lieu of the total airflow of the fan. This is a common misunderstanding we encounter associated C403.7.4 as well.

**Cost Impact:** The code change proposal will increase the cost of construction

For buildings that are already using an independent fan strategy (exhaust, supply, or balanced) or an integrated fan strategy that utilizes a small enough horsepower motor, this proposal will not increase or decrease the cost of construction. For buildings that are currently using standard AHU/Furnace fan motors as their mechanical ventilation fan, the cost of construction may increase as they will need to adjust their mechanical ventilation design strategy in order to comply.

RE241
**Proponent:** Aaron Gary, representing Self (aaron.gary@texenergy.org)

**2018 International Energy Conservation Code**

Revise as follows:

R403.6.1 (IRC N1103.6.1) Whole-house Whole-dwelling mechanical ventilation system fan efficacy. Fans used to provide whole-house whole dwelling mechanical ventilation shall meet the efficacy requirements of Table R403.6.1.

**Exception:** Where an air handler that is integral to tested and listed HVAC equipment is used to provide whole-house mechanical ventilation, the air handler shall be powered by an electronically commutated motor.

<table>
<thead>
<tr>
<th>FAN LOCATION</th>

<tr>
<td>Bathroom, utility room</td>
<td>90</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916.

**Reason:** “Whole-house” is too limiting a phrase as this Code governs, and these systems are installed, in dwellings other than houses with apartments that are 3-stories and lower being the most common. Further the term dwelling is used in the IMC in relation to ventilation systems in lieu of house.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Revision is clarifying in nature and does not change the requirements of the Code.
**2018 International Energy Conservation Code**

Revise as follows:

<table>
<thead>
<tr>
<th>FAN LOCATION</th>
<th>AIR FLOW RATE MINIMUM(CFM)</th>
<th>MINIMUM EFFICACY(CFM/WATT)</th>
<th>AIR FLOW RATE MAXIMUM(CFM)</th>
</tr>
</thead>
<tbody>
<tr>
<td>HRV or ERV</td>
<td>Any</td>
<td>1.2 cfm/watt</td>
<td>Any</td>
</tr>
<tr>
<td>Range hoods</td>
<td>Any</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
<tr>
<td>In-line fan</td>
<td>Any</td>
<td>2.8 cfm/watt</td>
<td>Any</td>

<tr>
<td>Bathroom, utility room</td>
<td>10</td>
<td>1.4 cfm/watt</td>
<td>&lt; 90</td>
</tr>
<tr>
<td>Bathroom, utility room</td>
<td>90</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916, Fan efficacy for HRV, ERV, balanced, and in-line fans shall be taken at a static pressure >= 0.2 in. w.c. Fan efficacy for range hoods, bathroom, and utility room fans shall be taken at a static pressure >= 0.1 in. w.c.

**Reason:** Fan efficacy varies as a function of static pressure, so it is necessary to identify the minimum static pressure required for determining the rating. These pressures are aligned with industry practice and ENERGY STAR’s requirements for reporting fan efficacy.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal clarifies a current requirement of the code. There is no expected change in construction costs.
**RE137-19**

IECC: TABLE R403.6.1 (IRC N1103.6.1)

**Proponent:** Mike Moore, representing Broan-NuTone (mmoore@newportventures.net)

**2018 International Energy Conservation Code**

Revise as follows:

TABLE R403.6.1 (IRC N1103.6.1)

WHOLE-HOUSE MECHANICAL VENTILATION SYSTEM FAN EFFICACY

<table>
<thead>
<tr>
<th>SYSTEM TYPE-FAN LOCATION</th>
<th>AIR FLOW RATE MINIMUM(CFM)</th>
<th>MINIMUM EFFICACY(CFM/WATT)</th>
<th>AIR FLOW RATE MAXIMUM(CFM)</th>

<td></td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916.

**Reason:** Changes proposed to this table are for clarification and simplification. First, the table should not be based on the location of the fan but on the type of fan being installed. For example, an HRV or ERV is not a location, but a system type. Balanced fans without heat recovery are currently omitted from the table, and should be listed along side HRVs and ERVs, which are also balanced systems. Because balanced fans are grouped with HRVs and ERVs, the use of the term "in-line fan" should be clarified to include supply and exhaust in-line systems (also not a location, but a system type). Finally, if a "bathroom" fan is installed in a hallway to provide ventilation (a typical installation location for whole-house mechanical ventilation systems), the current table is silent on the minimum efficacy required, because it does not address "hallway" fans. So, this proposal combines typical bathroom, utility room, range hood, and hallway exhaust fans into the category of "other exhaust fans"; no changes are made to the fan efficacies for these products (note that the minimum flow rate for intermittent range hoods permitted by the IRC is 100 cfm, corresponding to a minimum efficacy of 2.8 cfm/W under the original and proposed versions of the table). The last column can be deleted by changing the "Air Flow Rate Minimum" column heading to "Air Flow Rate".

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. These changes are for clarification and simplification purposes and do not increase or decrease the cost of construction.

Proposal # 5413
Proposed Changes to Whole-House Mechanical Ventilation System Fan Efficacy

2018 International Energy Conservation Code

Revise as follows:

**R403.6.1 (IRC N1103.6.1)** Whole-house mechanical ventilation system fan efficacy. Fans used to provide whole-house mechanical ventilation shall meet the efficacy requirements of Table R403.6.1.

**Exception:** Where an air handler that is integral to tested and listed HVAC equipment is used to provide whole-house mechanical ventilation, the air handler shall be Space heating or cooling air handlers shall not supply whole-house ventilation except when operating to provide heating or cooling, unless the air handler fan is powered by an electronically commutated motor and the project complies with R401.2.2 or R401.2.3.

**Reason:** The prescriptive path is configured to provide builders with options among items that provide roughly equivalent performance. In the case of ventilation, a central fan integrated system (i.e., a supply duct connected to the return trunk of the central air handler that relies on the air handler motor to deliver outdoor air) has much higher energy use than an exhaust-only system and should be modeled in the performance or ERI path to account for energy use associated with operation beyond “free” heating or cooling cycles. The major software programs are able to model such systems and account for their energy use. Following is a table showing the annual energy cost of operating a central fan integrated system versus a minimally code compliant exhaust-only system for a typical single-family home with a ventilation rate of 75 cfm. Annual energy cost of the CFI system ranges from $84 to $241 more than the exhaust-only system. Simulations were conducted in REM/Rate and are available here: https://www.dropbox.com/sh/yw3r9kwq9t4axg/AAD0N4lnij57N4qo2T160xcKa?dl=0.

<table>
<thead>
<tr>
<th>Climate Zone</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional Annual Energy Cost of CFI System Versus Code-Minimum Exhaust System</td>
<td>$241</td>
<td>$183</td>
<td>$135</td>
<td>$95</td>
<td>$84</td>
<td>$100</td>
<td>$107</td>
<td>$131</td>
</tr>
</tbody>
</table>

Assumptions for the “typical” home:

- Single family, detached, 2018 IECC compliant
- 2376 ft², 4 bed (CZ 1-3); 3564 ft², 4 bed (CZ 4-8)
- DUV: 75 cfm
- Air sealing: 5 ACH50 (CZ 1-2); 3 ACH50 (CZ 3-8)
- Heating/cooling: 80 AFUE furnace, 13 or 14 SEER AC, BLDC motor (ECM)
- Software: REM/Rate v15.5
- Energy prices: $0.1284/kWh; $1.307/therm

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Where central fan integrated systems are prescribed in homes not currently complying with the performance or ERI path, additional costs will be required to comply with such paths. If the builder wishes to remain within the prescriptive path, other options include: specifying central fan integrated systems that use an exhaust fan to provide ventilation when there is a call for ventilation but no call for heating or cooling (such systems are commercially available for ~$140 premium versus a CFI system), or specifying an exhaust or balanced ventilation system instead of a CFI system. Specification of an exhaust ventilation systems instead of a CFI system would be expected to reduce the first cost of the ventilation system.
RE139-19
IECC: R403.6.1 (IRC N1103.6.1) (New)

Proponent: Mike Moore, Newport Ventures, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Energy Conservation Code
Revise as follows:

R403.6 (IRC N1103.6) Mechanical ventilation (Mandatory). The building shall be provided with ventilation that complies with the requirements of the International Residential Code or International Mechanical Code, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

Add new text as follows:

R403.6.1 (IRC N1103.6.1) Heat or Energy Recovery Ventilation (Prescriptive). Dwelling units shall be provided with a heat recovery or energy recovery ventilation system in climate zones 7 and 8. The system shall be balanced with a minimum sensible heat recovery efficiency of 65% at 32°F (0°C) at a flow greater than or equal to the design airflow.

Reason: A recent study conducted by Pacific Northwest National Laboratory showed HRVs and ERVs to be cost effective in climate zones 7 and 8, with annual energy savings from $138 to $233 on an initial investment of ~$1500 installed (corresponding to a first cost premium of ~$840 versus an exhaust only system and one entry-level bath fan; yielding simple paybacks of 4-6 years). This proposal is aligned with recent changes across most of Canada to require heat recovery ventilation for dwelling units. This proposal would require heat or energy recovery ventilators only for those dwelling units following the prescriptive path in the coldest climate zones, which represents a conservative improvement to the code.

Cost Impact: The code change proposal will increase the cost of construction
The first cost of construction (including costs for appliance, equipment, and installation) is expected to increase by ~$830 compared to an exhaust-only system. Based on PNNL’s projected energy savings, this will be be recovered quickly, within 4-6 years. Assuming the $830 is financed in a traditional, 30-year mortgage at 4%, the annual energy savings of $138-$233 would generate $90 - $185 per year in cash flow for the home owner.

 Proposal # 5673
IECC: R403.6.12 (IRC N1103.6.2) (New)

Proponent: Mike Moore, Newport Ventures, representing Broan-NuTone (mmoore@newportventures.net)

2018 International Energy Conservation Code

R403.6.1 (IRC N1103.6.1) Whole-house mechanical ventilation system fan efficacy. Fans used to provide whole-house mechanical ventilation shall meet the efficacy requirements of Table R403.6.1.

Exception: Where an air handler that is integral to tested and listed HVAC equipment is used to provide whole-house mechanical ventilation, the air handler shall be powered by an electronically commutated motor.

Add new text as follows:

R403.6.2 (IRC N1103.6.2) Testing. Whole-house mechanical ventilation systems and outdoor air mechanical ventilation systems shall be tested and verified to provide the minimum ventilation flow rates required by Section R403.6. Testing shall be performed according to the ventilation equipment manufacturer's instructions, or by using a flow hood, flow grid, or other airflow measuring device at the mechanical ventilation fan's inlet terminals or grilles, outlet terminals or grilles or in the connected ventilation ducts. Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Reason: If installed incorrectly, whole-house mechanical ventilation systems can fail to deliver the minimum outdoor air needed to provide acceptable indoor air quality. A recent study in Florida* found that only three of 21 whole house mechanical ventilation systems had a flow rate near the design level. Because these systems perform a vital function in supporting building durability and occupant health, these systems should be verified for flow when installed. This requirement and text are aligned with ASHRAE 62.2, Ventilation and Acceptable Indoor Air Quality in Residential Buildings.

Cost Impact: The code change proposal will increase the cost of construction

Will increase the cost of construction where testing is not currently provided. Testing the airflow of a whole house mechanical ventilation system should take about 15-20 minutes. Assuming a skilled labor rate of $35/hr, the incremental cost for the test is estimated at $9-$12. The test can be completed by the same technician performing the blower door test. Also, there is no requirement for a third party to conduct the test, which can help moderate costs.
RE141-19
IECC: R403.6.2 (IRC N1103.6.3) (New)

Proponent: Aaron Gary, representing Self (aaron.gary@texenergy.org)

2018 International Energy Conservation Code
Add new text as follows:

R403.6.2 (IRC N1103.6.3) Testing (Mandatory) The fans used to provide whole-dwelling mechanical ventilation shall be tested according to the manufacturer's instructions or RESNET/ICC 380. Testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official.

Reason: Much blood has been spilled debating the appropriate amount of outdoor air that should be introduced into a dwelling via mechanical ventilation. While all this focus has been applied to the design calculations, much less has been turned to the actual air that is delivered by these systems. In my experience as a 3rd party verifier and HVAC contractor, the amount of air that is actually being delivered is as crucial as selecting the right design and equipment.

The commissioning of these systems is simply not required by Code and therefore it is not happening for a majority of Code dwellings. When more outdoor air is provided than intended it can overwhelm the right-sized (R403.7) heating and cooling equipment's ability to process this air. The impact is human comfort complaints, potential moisture issues in humid climates, and lost energy efficiency.

Further, 3rd party verification and testing of the mechanical ventilation system is already part of the ERI path through its inclusion in ANSI/RESNET/ICC 301. It is not required however in the Prescriptive or Performance paths.

Cost Impact: The code change proposal will increase the cost of construction
This proposal will increase the cost of construction for dwellings following the Prescriptive and Performance paths through the IECC not through additional or change in product but by requiring additional testing similar to Air Leakage testing (R402.4) and Duct Leakage testing (R403.3.3). This proposal will not increase the cost of construction for dwellings following the ERI path through the IECC as this test is already mandatory under ANSI/RESNET/ICC 301.
2018 International Energy Conservation Code

Add new text as follows:

R403.6.2 (IRC N1103.6.2) Airflow measurement. The airflow rate required is the quantity of outdoor ventilation air supplied and/or indoor air exhausted by the whole-house mechanical ventilation system installed, and shall be measured using a calibrated flow hood, flow grid, or other airflow measuring device. Ventilation airflow of systems with multiple operating modes shall be tested in all modes of operation designed to meet Section R403.6. Where required by the code official, testing shall conducted by an approved third party. A written report of the results of the test, indicating the verified airflow rate, shall be signed by the party conducting the test and provided to the code official.

Reason: The proposal adds a provision establishing the "measurement" of airflow associated with the central energy-using system of the home, its heating ventilation and air-conditioning system. The language, while derived from the provisions of ASHRAE Standard 62.2-2016, is written in useable, understandable and enforceable, mandatory language.

Cost Impact: The code change proposal will increase the cost of construction
IECC LLC has experience with the implementation training and technical support activities associated with State Energy Offices, State Fire Marshall's Offices and Departments of Housing, Buildings and Construction for 2009 and 2012 IECC adoptions in Iowa, the 2009 and 2012 IECC adoptions in Kentucky, the 2012, 2015 and 2018 adoptions in Illinois and more recently the 2015 and 2018 adoptions throughout the greater Nashville, TN metro community. In conducting these activities, it is common to solicit, discuss and evaluate the pricing structures available in the residential housing sector. The building diagnostic services discussed include a code-mandated blower door pressure test, a code-mandated duct pressure leakage test (pending location of ductwork), as well as services less commercialized in the residential housing sector; infrared thermography and HVAC ventilation system airflow validation. It is common that when a code mandated test is "bundled" with one of the other home diagnostic services these price points are discounted.

Proposition 5575
RE143-19
IECC: R403.7 (IRC N1103.7), ACCA Chapter 6 (IRC Chapter 44)

Proponent: David Bixby, representing Air Conditioning Contractors of America

2018 International Energy Conservation Code
Revise as follows:

R403.7 (IRC N1103.7) Equipment sizing and efficiency rating (Mandatory). Heating and cooling equipment shall be sized in accordance with ACCA Manual S based on building loads calculated in accordance with ACCA Manual J or other approved heating and cooling calculation methodologies. New or replacement heating and cooling equipment shall have an efficiency rating equal to or greater than the minimum required by federal law for the geographic location where the equipment is installed. Minimum criteria for the proper design, equipment selection, installation, and commissioning of HVAC systems shall comply with ACCA 5 QI.

Add new standard(s) as follows:

ANN/ACCA 5 QI -2010: HVAC Quality Installation Specifications

Reason: ANSI/ACCA 5 QI Standard (HVAC Quality Installation Specification) covers the initial HVAC system design, including system sizing, equipment selection, duct sizing, start-up and commissioning. It was developed by a broad coalition of industry stakeholders and is available for free download (www.acca.org/quality).
In September 2014, the U.S. National Institute of Standards and Technology (NIST) published, "Sensitivity Analysis of Installation Faults on Heat Pump Performance." This report presents evidence that non-compliance with the ANSI/ACCA 5 QI Standard results in quantifiable increases in energy usage and operating costs. The NIST report demonstrated that the increased energy consumption can be greater than 50% when multiple deficiencies (e.g., duct leakage, low refrigerant charge, equipment oversizing, airflow, etc.) are encountered. While the industry focuses on equipment efficiency, the real efficiency of the system (installed efficiency) is determined by its proper design, installation, and commissioning.

The ACCA 5 QI Standard has been adopted by the Consortium for Energy Efficiency (CEE; a consortium of utilities with programmatic efforts in energy efficiency) as its definition for the minimum requirements for HVAC installations. In addition, the "HVAC Commissioning Checklist" for EPA Energy Star® certified homes, Green Building Communities, and HERS Rating is embodied in the requirements of the ANSI/ACCA 5 QI protocol, thereby insuring the performance of HVAC systems in new homes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Cost of construction will be unaffected other than the extra time to properly design, size and install an HVAC system according to minimum industry accepted practices.
**2018 International Energy Conservation Code**

Revise as follows:

**R403.12 (IRC N1103.12) Residential pools and permanent residential spas (Mandatory)**. Residential swimming pools and permanent residential spas that are accessory to detached one- and two-family dwellings and townhouses three stories or less in height above grade plane and that are available only to the household and its guests shall be in accordance with APSP 15.

**Reason:** This section provides a reference to a specific standard with no alternative provided. The section provides no metrics or values that can be used for calculations for trade-offs. Additionally, both R403.10 and R403.11, which address similar subjects, are labeled mandatory and there is no reason for this to be inconsistent.

Note, the SEHPCAC has a proposal to eliminate use of the labels “prescriptive” and “mandatory” in favor of a tabular method of identifying non-tradeable requirements. If that proposal is successful ICC staff have stated that sections being individually approved as “mandatory” will instead have their respective section numbers added to the new C407.2 table of requirements that are non-tradeable in the performance path.

This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This code change proposal does not add to nor detract from design or construction requirements.
Proponent: Lauren Urbanek, representing Natural Resources Defense Council (lurbanek@nrdc.org)

2018 International Energy Conservation Code

Add new definition as follows:

**DIMMER. (IRC N1101.6).** A control device that is capable of continuously varying the light output and energy use of light sources.

Revise as follows:

**HIGH-EFFICACY LAMPS. (IRC N1101.6).** Compact fluorescent lamps, light-emitting diode (LED) lamps, T-8 or smaller diameter linear fluorescent lamps, or other lamps Any lamps with an efficacy of not less than the following:

1. 70 lumens per watt for lamps over 40 watts.
2. 60 lumens per watt for lamps over 15 watts to 40 watts.
3. 50 lumens per watt for lamps 15 watts or less.

Add new definition as follows:

**OCCUPANT SENSOR CONTROL. (IRC N1101.6).** An automatic control device or system that detects the presence or absence of people within an area and causes lighting, equipment or appliances to be regulated accordingly.

Revise as follows:

**R404.1 (IRC N1104.1) Lighting equipment (Mandatory).** Not less than 90 percent of the All permanently installed lighting fixtures shall contain only high-efficacy lamps.

Add new text as follows:

**R404.2 (IRC N1104.2) Lighting Controls (Mandatory).** Permanently installed lighting fixtures shall be controlled with either a dimmer, an occupant sensor control, or other control that is installed or built into the fixture.

**Exception:** Lighting controls shall not be required for the following:

1. Bathrooms
2. Hallways
3. Exterior lighting fixtures
4. Lighting designed for safety or security

**Reason:** The purpose of this code change proposal is to increase lighting efficiency to better align with the current lighting market and upcoming changes to lighting standards.

DOE projects that light-emitting diode (LED) lighting will represent about half of the market share in 2020, and nearly 85% of the market share by 2030[1]. Goldman Sachs projects an even faster uptake of LEDs, projecting a full market penetration by the early 2020s[2]. The current definition of a “high efficacy lamp” in the energy code is outdated: it was added to the code in 2009, when LED market share was close to zero, and has not been updated since then. In fact, the definition no longer represents the “high efficacy” share of the market. New lighting standards will take effect in 2020 that will eliminate all bulbs on the market with efficiencies lower than 45 lumens per watt. Therefore, by the time the 2021 code is published, some of the bulbs currently defined by the IECC as “high efficacy” will be illegal to sell. Given these market and standard changes, the definition must be updated to remain relevant.

Once the updated federal standard takes effect, the baseline, least-efficient bulb on the market will no longer be an incandescent or even a halogen, but a compact fluorescent light bulb. In many cases, LEDs are close in price to – or even cheaper than - CFL alternatives while being a clearly superior product. CFLs contain mercury, are slow to come to full light, and few models are dimmable. In contrast, LEDs come in a wide range of light outputs, bulb shapes, color temperatures, socket types, do not contain mercury, and the vast majority of models are dimmable. Virtually all LEDs on the market today meet the 70 lumens per watt requirement specified in this proposal.

The table below summarizes a recent Home Depot search for a dimmable 60-watt equivalent bulb, one that gives off approximately 800 lumens of light. The LED bulb is significantly more efficient and longer-lasting than the CFL or halogen option. Recent searches found that sale prices of LED bulbs are often even lower than a halogen equivalent. Note that the CFL bulb is not dimmable; there was no equivalent dimmable CFL option. A separate search for dimmable CFL bulbs[3] shows that they are in the range of at least $7 per bulb and not widely available. The halogen option will not be legal to sell starting January 1, 2020.
The proposal also requires lighting controls, in the form of either a dimmer, occupancy control, or other such control (such as an automatic daylight sensor). Both dimmers and occupancy controls will save even more energy. Dimmers can reduce energy use by about 20%, while occupancy sensors reduce wasted energy by around 30%[7]. These controls are essentially permanent, with an extremely long lifetime. Connected occupancy controls, such as those in use with a home automation system, can add value and convenience to homeowners, as well.

Cost Impact: The code change proposal will increase the cost of construction. This proposal will increase the cost of construction due to the increased cost of dimmer switches or occupancy controls. However, there is little, if any, incremental cost to move from CFL to LED bulbs even today, and the costs of this technology will continue to decrease. Given the change in technology and the improved federal standards, by the time the 2021 code is adopted, there may be no incremental cost to purchase a LED bulb.
RE146-19

IECC: R202 (IRC N1101.6), R404.2 (IRC N1104.2) (New), R404.2.1 (IRC N1104.2.1) (New), R404.2.2 (IRC N1104.2.2) (New)

2018 International Energy Conservation Code

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

ELECTRIC VEHICLE. An automotive-type vehicle for on-road use, such as passenger automobiles, buses, trucks, vans, neighborhood electric vehicles, and electric motorcycles, primarily powered by an electric motor that draws current from a building electrical service, EVSE, a rechargeable storage battery, a fuel cell, a photovoltaic array, or another source of electric current.

ELECTRIC VEHICLE SUPPLY EQUIPMENT (EVSE). The conductors, including the ungrounded, grounded, and equipment grounding conductors, and the electric vehicle connectors, attachment plugs, and all other fittings, devices, power outlets, or apparatus installed specifically for the purpose of transferring energy between the premises wiring and the electric vehicle.

Add new text as follows:

R404.2 (IRC N1104.2) Electric vehicle ready parking (Mandatory). Where parking is provided, electric vehicle ready parking spaces shall be provided in compliance with Sections R404.2.1 and R404.2.2. Where more than one parking facility is provided on a site, electric vehicle ready parking spaces shall be calculated separately for each parking facility.

Exception: This section does not apply to parking spaces used exclusively for trucks or delivery vehicles.

R404.2.1 (IRC N1104.2.1) Electric vehicle ready parking spaces. Not less than two percent, but not less than one, parking spaces shall be electric vehicle ready parking and shall comply with Section R404.2.2.

Exception: Single-family and two-family dwelling units shall provide a not less than one electric vehicle ready parking space.

R404.2.2 (IRC N1104.2.2) Electric vehicle service equipment (EVSE) ready circuit. Each electric vehicle ready parking space shall be provided with a minimum 40-ampere branch circuit to accommodate a future dedicated Level 2 EVSE. The circuit shall terminate in a NEMA 6-50 or NEMA 14-50 receptacle or a suitable electrical connector rated for 240 volts or greater service. The circuit shall have no other outlets. The service panel shall provide sufficient capacity and space to accommodate the circuit and over-current protective device. A permanent and visible label stating “EV READY” shall be posted in a conspicuous place at both the service panel and the circuit termination point.

The increase in EV sales will be accompanied by an increase in demand for on-site residential EV charging capacity. Up to 5.5 million chargers, which will be mostly installed in homes, will be required by 2025 to support a fleet of seven million EVs. See EEI and IEI, “Plug-in Electric Vehicle Sales Forecast Through 2025 and the Charging Infrastructure Required.” In the near term this will likely involve the installation of Level 2 chargers, which require an additional 240-volt circuit. The cost of retrofitting a home to accommodate a Level 2 charger, which can recover the full range of a typical EV in 10 hours or less, will be a financial burden on homeowners. Adding a requirement for EV-ready parking spaces to the code will facilitate future Level 2 charger installations, which will eventually become practically ubiquitous, at a much lower cost.

Increased adoption of EVs will have a positive effect on overall U.S. household energy spending and carbon emissions. In terms of energy savings, EV fuel economy is, on average, more than three times more efficient than conventional gasoline-fueled counterparts. Even when compared over the full lifecycle of fuel production and use, the average EV consumes less than half the energy per vehicle mile traveled. See InsideEVs, “Efficiency Compared: Battery-Electric 73%, Hydrogen 22%, ICE 13%,” available at https://insideevs.com/efficiency-compared-battery-electric-73-hydrogen-
and Argonne National Laboratory, “Greenhouse Gases, Regulated Emissions, and Energy use in Transportation Model,” available at https://greet.es.anl.gov/index.php. NRDC and EPRI found that if 50 percent of personal vehicle miles traveled were powered by electricity in 2050, the U.S. would realize annual emissions reductions of 550 million metric tons of carbon dioxide. See NRDC, “Study: Electric Vehicles Can Dramatically Reduce Carbon Pollution from Transportation, and Improve Air Quality,” available at https://www.nrdc.org/experts/luke-tonachel/study-electric-vehicles-can-dramatically-reduce-carbon-pollution. The ideal solution would get this code change in place by the time adoption rates are expected to accelerate, which would help facilitate adoption of EVs and therefore lead to more efficient energy consumption and lower household carbon emissions.

Cost Impact: The code change proposal will increase the cost of construction
The additional branch circuit and associated wiring and conduit required to make parking spaces EV-ready will incrementally increase the cost of construction. But the cost of a retrofit to add the electrical panel capacity for a common Level 2 charger will be much higher—up to $2,000. See Realtor.com, “Electric Car Charger Installation in Your Home: True Costs—and What You Need to Know,” available at https://www.realtor.com/advice/home-improvement/installing-electric-vehicle-charger/.
2018 International Energy Conservation Code

Add new text as follows:

R404.2 (IRC N1104.2) Electric readiness (Mandatory) Systems using gas or propane water heaters, dryers, or conventional cooking equipment to serve individual dwelling units shall comply with the requirements of Sections R404.2.1 and R404.2.2. All water heating systems shall comply with Section R404.2.3.

R404.2.1 (IRC N1104.2.1) Receptacle. A dedicated 125-volt, 20-amp electrical receptacle that is connected to the electric panel with a 120/240 volt 3 conductor, 10 AWG copper branch circuit, shall be provided within 3 feet from each gas or propane water heater, dryer, and conventional cooking equipment, accessible with no obstructions.

R404.2.2 (IRC N1104.2.2) Electrification-ready circuits. Both ends of the unused conductors shall be labeled with the word “SPARE” and be electrically isolated. A single pole circuit breaker space shall be reserved in the electrical panel adjacent to each circuit breaker for the branch circuit and labeled with the words “FUTURE 240V USE.”

R404.2.3 (IRC N1104.2.3) Water heater space. An indoor space that is at least 3 feet by 3 feet by 7 feet high shall be available within 3 feet of the water heater.

Exception: The water heater space requirement does not need to be met where a heat pump water heater is installed.

Reason: This proposal enhances customer choice by making it easy for homeowners to choose either electric or gas appliances and water heating equipment. By ensuring that a home built with gas or propane can easily accommodate future electric appliances and equipment, this proposal protects homeowners from future costs, should natural gas become less affordable or even unavailable over the life of the building. As the electric grid becomes cleaner, and high-efficiency electric heat pump technology increasingly offers utility bill and pollution reduction benefits over gas, more customers may want to transition from natural gas to electric space and water heating. Federal, state, and local environmental and public health policies may also encourage, or even require the transition in some areas over the life of the building. Electric-ready requirements will protect customers from potential high retrofit costs.

Cost Impact: The code change proposal will increase the cost of construction. The cost of meeting these electric-ready requirements when the house is being built, walls are open, and the trades are already on-site, is marginal. In comparison, the cost of retrofitting a building for these requirements can be orders of magnitude higher and act as a barrier for the homeowner to choose electric appliances. Not making new buildings electric-ready would leave homeowners exposed to potentially high retrofit costs in the future and will greatly inhibit customer choice.
IECC: R404.1.1 (IRC N1104.1.1) (New)

Proponent: Eric Makela, representing New Buildings Institute (ericm@newbuildings.org)

2018 International Energy Conservation Code

Add new text as follows:

Exceptions:

1. Solar-powered lamps not connected to any electrical service.
2. Luminaires controlled by a motion sensors.

Reason: The IECC does not have any specific requirements for exterior lighting for residential buildings. This may not be a significant issue for single-family homes, duplexes and townhomes, but it is quite significant for Type-R occupancies like multifamily that are far more likely to have parking lots and other exterior lighting like their counterparts subject to the commercial code. A 4-story multifamily building with exactly the same systems and layout would therefore be subject to exterior lighting requirements while a 3-story variation would not. This creates a loophole in the code for low-rise R-occupancies.

This proposal directs exterior lighting for these occupancies to the commercial code and its LPD requirements. Small R-occupancy buildings are little different than small commercial buildings which are already subject to those requirements. The proposal exempts solar-powered lighting and any lighting controlled by a motion sensor.

When applied to the low-rise multifamily prototype developed by Pacific Northwest National Laboratories for the code determination studies, this requirement saved up to 0.5% (based on climate zone) whole building energy over the 2015 IECC. Since both 2018 and 2015 lack exterior lighting requirements, this is a reasonable approximation of savings.

Cost Impact: The code change proposal will increase the cost of construction. However, the proposal refers only R-occupancies to the existing commercial exterior lighting requirements, which already cover smaller commercial buildings.

For example, a base light fixture cost for a 70 W halogen fixture is $118.00 (https://www.lightingsupply.com/stonco-sla71mal-6) and the cost for an enhanced 80 W LED light fixture that will meet the proposed efficacy requirements is $158.33 (https://www.lightingsupply.com/best-lighting-products-ledmpal80-1-5k)
R404.2 (IRC N1104.2) Exterior lighting controls Where the total permanently installed exterior lighting power is greater than 30 watts, the exterior lighting permanently mounted to a residential building, or to other buildings on the same lot, shall comply with the following:

1. Lighting shall be controlled by a manual on and off switch which permits automatic shut off actions.
2. Lighting shall automatically turn off when daylight is present during the daytime and satisfies the lighting needs.
3. Lighting shall automatically turn off by time-switch control or when activity has not been detected for 15 minutes or more.
4. Controls that override automatic shut off actions shall not be allowed unless the override automatically returns automatic control to its normal operation within six twenty-four hours.

Reason: The increase in construction cost is due to the addition of a simple photocell or use of exterior lighting fixtures with integral photocell. These are inexpensive and readily available in many options at retailers and electrical distributors. Photocell costs are often under $10. Exterior light fixtures with integral photocell (and often including a motion detector), are available for a total packaged cost from the sub $20 range, up to many times this cost based the fixture style, grade and aesthetics. The added cost of the controls is typically minimal, or an inseparable option included with the exterior lighting fixture altogether. The 2014 CEE report “Lighting Controls Market Characterization Report”, identifies the use of a photosensor or timer can save, on the average, 15 up to 60KWh per year, based on the efficacy of the light source that is controlled.

Cost Impact: The code change proposal will increase the cost of construction
The increase in construction cost is due to the addition of a simple photocell or use of exterior lighting fixtures with integral photocell. These are inexpensive and readily available in many options at retailers and electrical distributors. Photocell costs are often under $10. Exterior light fixtures with integral photocell (and often including a motion detector), are available for a total packaged cost from the sub $20 range, up to many times this cost based the fixture style, grade and aesthetics. RE150-19
IECC: R406.2 (IRC N1106.2)

Proponent: Joel Martell, representing National Association of Home Builders (jmartell@nahb.org)

2018 International Energy Conservation Code

Revise as follows:

R406.2 (IRC N1106.2) Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The proposed total building thermal envelope UA which is sum of U-factor times assembly area, shall be greater than or equal to the building thermal envelope UA using the prescriptive U-factors from Table R402.1.2 multiplied by 1.15 in accordance with Equation 4-1, levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

\[ \text{UA}_{\text{proposed design}} = 1.15 \times \text{UA}_{\text{prescriptive reference design}} \quad \text{Equation 4-1} \]

Reason: This proposal increases the flexibility of the thermal envelope minimums that are part of the ERI compliance path mandatory requirements. The minimum thermal envelope requirements are that of the 2009 IECC prescriptive table. While this could be considered a reasonable “backstop”, the flexibility it offers is minimal; for example both the 2009 and 2018 IECC require R-20 walls in climate zone 5 and because the 2009 IECC is the minimum, there is no ability to trade off wall insulation in climate zone 5, but wall insulation can be traded off in zones 3, 4, 7 & 8 since the wall insulation requirements increased from the 2009. This proposal preserves this “reasonable envelope” concept and applies it to the ERI, but, rather than pointing to the prescriptive tables in a previous version of the IECC, the thermal backstop becomes a percent UA trade-off. The UA calculation will be performed internally with the compliance software and will not require any additional information to be entered as all the necessary information is already entered (component area and Ufactors/ R-values). This should not be problematic as it is already done for windows. This 15% will prevent installing single pane windows and significant reductions in the building envelope components.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The increased flexibility offered by this proposal will provide an opportunity for builders and designers to cost optimize an efficient home and potentially reduce the cost of construction.

Proposal # 4294

RE150-19
Revised as follows:

R405.2 (IRC N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table R402.1.1 or R402.1.3 of the 2009 International Energy Conservation Code. Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

Add new text as follows:

Reason: The purpose of this code change is to help ensure long-term energy savings and occupant comfort by applying a reasonable, consistent minimum mandatory thermal envelope backstop across the IECC’s two performance-based compliance paths. Since 2015, the newest IECC compliance path, the Energy Rating Index (R406), has already included a minimum mandatory thermal envelope backstop based on the 2009 IECC prescriptive requirements. While a minimum backstop is most important for the ERI, it would also be useful if applied to the simulated performance alternative in Section R405. This proposal will accomplish this objective.

An important part of the logic behind the minimum thermal envelope requirements for the ERI applies to the performance path in Section R405 as well -- a well-built thermal envelope provides long-term energy savings and improved comfort for occupants over the lifetime of the home, and upgrades to the thermal envelope are easiest to incorporate (and most cost-effective) at construction. This is consistent with the intent of the IECC set forth in Section R101.3. Specifically, the IECC is intended to "regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building." Regardless of the compliance option selected by the code user, the IECC should require a reasonable minimum level of performance by the home’s permanent thermal envelope. As a result, this proposal would apply the same minimum mandatory requirements, including envelope requirements, to Section R405 compliance as currently apply to Section R406 compliance.

To our knowledge, the 2009 IECC backstop in Section R406.2 has been adopted by every state that has adopted the ERI as part of the 2015 or 2018 IECC. A trade-off backstop recognizes the crucial importance of a reasonably efficient thermal envelope, irrespective of the efficiency tradeoffs among various other building components. While we would prefer an even more robust backstop than the 2009 prescriptive requirements (such as the 2015 requirements, which were established in 2018 for ERI compliance that includes on-site generation), the 2009 requirements are at least a reasonable starting place and are consistent with the current backstop for ERI.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Because this proposal only establishes a trade-off backstop to an alternative compliance path and not a prescriptive code requirement (the prescriptive requirements are already much more efficient than the proposed new backstop levels), and because most homebuilders are likely already meeting or exceeding these requirements, we conclude that there will not necessarily be any cost impact.
**2018 International Energy Conservation Code**

Revise as follows:

**R405.1 (IRC N1105.1) Scope.** This section establishes criteria for compliance using simulated energy performance analysis. Such analysis shall include heating, cooling, mechanical ventilation and service water heating energy only. Devices or practices for which no credit is claimed and devices which are not installed shall not increase or decrease the proposed design energy use.

### Thermally isolated sunrooms

| None.                                                                                                                                             | As proposed |

### Air exchange rate

| The air leakage rate at a pressure of 0.2 inch w.g. (50 Pa) shall be Climate Zones 1 and 2: 5 air changes per hour. Climate Zones 3 through 8: 3 air changes per hour. | The measured air exchange rate. |
|                                                                                                                                                    | The mechanical ventilation rate shall be in addition to the air leakage rate and shall be as proposed. |
| The mechanical ventilation rate shall be in addition to the air leakage rate and shall be the same as in the proposed design, but not greater than 0.01 \times CFA + 7.5 \times (N_{br} + 1) | |
| where:                                                                                                                                            | |
| CFA = conditioned floor area, ft².                                                                                                               | |
| N_{br} = number of bedrooms.                                                                                                                     | |
| Energy recovery shall not be assumed for mechanical ventilation.                                                                                | |

### Mechanical ventilation

| Where mechanical ventilation is not specified in the proposed design: None. Where mechanical ventilation is specified in the proposed design, the annual vent fan energy use, in units of kWh/yr, shall equal: \( \left( U_{ei} \right) \times \left[ 0.0876 \times CFA + 65.7 \times (N_{br} + 1) \right] \) | As proposed |
| where: \( e_i \) = the minimum exhaust fan efficacy, as specified in Table R403.6.1, corresponding to a flow rate of 0.01 \times CFA + 7.5 \times (N_{br} + 1) | |
| CFA = conditioned floor area, ft².                                                                                                             | |
| N_{br} = number of bedrooms.                                                                                                                    | |

### Internal gains

| IGain, in units of Btu/day per dwelling unit, shall equal: 17,900 + 23.8 \times CFA + 4,104 \times N_{br} where: CFA = conditioned floor area, ft². N_{br} = number of bedrooms. | Same as standard reference design. |

### Internal mass

| Internal mass for furniture and contents: 8 pounds per square foot of floor area.                                                                 | Same as standard reference design, plus any additional mass specifically designed as a thermal storage element but not integral to the building envelope or structure. |

### Structural mass

<p>| For masonry floor slabs: 80 percent of floor area covered by R-2 carpet and pad, and 20 percent of floor directly exposed to room air. | As proposed |
| For masonry basement walls: as proposed, but with insulation as specified in Table R402.1.4, located on the interior side of the walls. | As proposed |
| For other walls, ceilings, floors, and interior walls: wood frame construction.                                                               | As proposed |</p>

</table>
Onsite Renewables | No onsite renewables | Same, or
|                  |                        | Onsite renewables shall reduce the proposed design energy use.

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

° C = (°F - 32)/1.8, 1 degree = 0.79 rad.

a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[
AF = AF_s \times FA \times F
\]

where:

\( AF \) = Total glazing area.

\( AF_s \) = Standard reference design total glazing area.

\( FA \) = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 \times below-grade boundary wall area).

\( F \) = (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions. Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil. Below-grade boundary wall is any thermal boundary wall in soil contact. Common wall area is the area of walls shared with an adjoining dwelling unit.

L and CFA are in the same units.

i. Lighting verification. For installed lighting a fixture/lamp schedule for the watts by room shall be provided for the interior lighting. Lighting schedule shall be summed to compute the total proposed watts.

j. Refrigerator verification. The annual kWhr of refrigerators shall be as specified by the EnergyGuide label" with Subpart C, U.S. 16 CFR 305
(Effective January 1, 2021). Where there are multiple refrigerators, the annual kWhr shall be summed.

k. **Clothes washer verification.** The annual kWhr of clothes washers shall be as specified by the EnergyGuide label" with Subpart C, U.S. 16 CFR 305 (Effective January 1, 2021). Where there are multiple clothes washers, the highest kWhr shall be used.

l. **Dishwasher verification.** The annual kWhr of dishwashers shall be as specified by the EnergyGuide label" with Subpart C, U.S. 16 CFR 305 (Effective January 1, 2021). Where there are multiple dishwashers, the highest kWhr shall be used.

m. **Drain water heat recovery.** Drain water heat recovery unit efficiency shall be in accordance with Section R403.5.4 This credit shall require a drain water heat recovery unit be installed on all showers.

n. **Balanced ventilation verification.** Ventilation shall be in accordance with IRC 1505 which allows a 30% reduction in ventilation rate. To receive this credit exhaust-only bath fans shall be on a 20-minute timer or other device that shuts off the bath fan when not in use.

o. **Heat recovery verification.** Heat recovery ventilation or energy recovery ventilation shall be a reduction in energy use as specified by the manufacturer.

p. **On-site renewables verification.** Energy from on-site renewables shall be a reduction in the residence's energy use based on an approved calculation of on-site renewable energy production.

**Reason:** This code change proposal expands the performance calculation to include additional options for energy savings. In all cases these options are neutral if not taken, but offer credits if taken. This change specifies efficiency measures in a way that makes them enforceable. Multiple jurisdictions reduce specific IECC/IRC energy requirements because those requirements seem difficult for some situations. For example air tightness and specific insulation levels are reduced in many jurisdictions. This code change gives the code user new options to increase energy efficiency in one area to compensate for another area.

The options in this proposal were picked because they have significant impact, can be specified in simple terms, and can be specified based on existing tests or standards. The performance section user can use or not use any of these options. Options not used do not affect the performance calculation, because the standard reference design and the proposed design become the same.

The ERI already includes the items listed here. The performance calculation should also include those items.

Several measures of efficiency in this change are based on existing tests or labels. Clothes washer, refrigerator and dishwasher annual energy use is on the federally required label. These are the yellow Energy Guide labels.

**Lighting:**

Lighting power density (LPD) is a concept usually applied to commercial spaces. The LPD for the reference design was selected based on Table C405.3.2.1 in the commercial IECC. The reference design (base case) of 0.61 was the lowest LPD from several that were similar to residential space. The similar values were “Dormitory” at 0.61; “Multifamily” at 0.68; and “Hotel/Motel” is 0.75.

The proposed lighting annual energy use is calculated as hours of use times watts. An average use of 1000 hours per year (2.74 hours per day) is within the reported range for actual light use and is presumed. Based on this use per day the proposed lighting annual energy use is simply 1 kWh per watt of installed lighting.

Lighting wattage will need to be verifiable, as lighting savings are based on the watts of installed lighting. Code officials are unlikely to have the time to count watts in a house. A list of lighting by room would give enough detail to spot check one or more rooms in a house.

Refrigerator, Clothes Washer, and Dishwasher:

These appliances all required to have EnergyGuide labels by federal law. The EnergyGuide labels all have kWhr/year on the label.

**Drain water heat recovery:**

The drain water heat recovery applies to showers. Showers average over 25% of the service hot water use in homes. The devices recover heat from water gong down the drain water and use it to preheat the incoming water. The heat recovery of a unit is rated by tests in CSA B55.1, which is already required in the code. (Section R403.5.4).

**Ventilation:**

Balanced ventilation performs better, requires less ventilation and uses less energy. Approved group A code changes (M22 and RM22) specified
that balanced ventilation required 30% less ventilation, hence the 30% reduction in the performance calculation.

Overall, this proposed change allows residences to achieve the energy efficiency in the IECC/IRC in a variety of ways. It comes with the philosophy that the goal is to reduce energy use. However, there are many ways to achieve that energy efficiency and the code user should be given the flexibility to choose how to achieve energy efficiency.

The performance calculation should also account for heating, cooling, and water heating equipment efficiency. A separate change restores the performance calculation credit for higher efficiency heating, cooling and water heating equipment.

Reference standard.

The proposed lighting energy use is calculated as hours of use times watts. An average use of 1000 hours per year (2.75 hours per day) is within the reported range for actual light use and is presumed. The proposed lighting annual energy use is simply 1 kWh per watt of installed lighting.

Lighting wattage will need to be verifiable, as lighting savings are based on the watts of installed lighting. Code officials are unlikely to have the time to count watts in a house. A list of lighting by room would give enough detail to spot check one or more rooms in a house.

Refrigerator:

This will favor, but not require, refrigerators without though the door ice, with freezer on the top rather than side-to-side. These refrigerators use less energy.

Equipment verification:

One big issue with having options for more efficient equipment and devices is inspection and verification. The efficiency used must be easy to verify.

Overall, this proposed change allows residences to achieve the energy efficiency in the IECC/IRC in a variety of ways. It comes with the philosophy that the goal is to reduce energy use. However, there are many ways to achieve that energy efficiency and the code user should be given the flexibility to choose how to achieve energy efficiency.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction This will offer options for achieving efficient homes. If anything options typically decrease costs.
IECC: R405.3

Proponent: Ted Williams, representing American Gas Association (twilliams@aga.org)

2018 International Energy Conservation Code

Revise as follows:

R405.3 (IRC N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration's State Energy Data System Prices and Expenditures reports. Code officials shall be permitted to require time-of-use pricing in energy cost calculations.

Exception: The energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier 3.16 for electricity and 1.1 for fuels other than electricity shall be used or other multipliers for national or regional annual average energy consumption from nationally-recognized and validated data sources.

Reason: The proposed change is consistent with the proposed change to C407.3 and is based upon the source energy metric usage in Federal energy programs including Energy Star for Commercial Buildings and Home Energy Score. This revised exception provides the only means of assessing energy performance on fuel cycle energy consumption and ultimately carbon footprints since site energy metrics alone cannot account for these upstream energy system losses. In addition, the allowance in the proposed exception language for use of “other multipliers” addresses a persistent criticism of national average multipliers, which do not reflect regional or local mixes of renewable energy in meeting building demands, and encourages authorities having jurisdiction to use locally-relevant multipliers that are available from utilities and other sources. Also, greater usefulness of the exception is critical since the basic requirements of R405.3 focusing on energy cost is not consistent with the intent of the IECC as stated in R101.3, which addresses energy use and conservation, not energy cost.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The proposal would not increase the cost of construction since the proposal is for changes to an exception. If the use of source energy metrics allows more alternatives for achieving energy performance improvements, it may decrease construction costs ultimately.

Proposal # 5579

RE153-19

\(a\). Values represent averages for the United States.

**Reason:** The world of energy production and energy storage and choices of energy supply is changing rapidly. The current language is outdated and does not account for all of the changes going on and needs to be revised. This proposal will make the provision more flexible for building designers, building owners, and code officials. By allowing the use of site energy, which was allowed in previous versions of the IECC, the performance path can be based on real measured data. By updating source energy estimates, there will be more information provided to code officials and building owners.

More buildings are producing and storing energy on-site, so it does not make technical or analytical sense to require the use of outdated “source energy” estimates.

**Site Energy**
Allowing the use of site energy is more appropriate for buildings that are producing or storing energy on-site. In the future, many buildings will be producing energy and storing energy, along with consuming energy. Building systems may be consuming energy that was produced from an off-site energy grid and/or produced from an on-site energy production system and/or delivered from an off-site energy storage system (e.g., a grid battery or EV battery) and/or delivered from an on-site energy storage system, (e.g., and battery or fuel storage tank or thermal energy storage system). At the same time, the building may be producing energy that is used by building equipment, sent to an on-site energy storage system, or exported to another building (or buildings) or to the energy grid.

In a letter to DOE, ASHRAE said:

"the Society believes that the multiple and varying weighting factors and algorithms required for estimating source energy conversions are often inconsistent and ultimately cloud and complicate understanding. Since source energy conversion factors vary widely from place to place and across time, the use of fixed national average conversion factors could lead to inconsistent estimates of consumption."

"Thus, in this case the best method for determining if a building is a NZEB is to look at the energy crossing the boundary at the site of the building; hence "site" energy is the best choice to use." (emphasis added)

Site energy was part of the exception for many years until it was removed. There are many reasons to allow site energy to be used as an alternative to source energy or energy costs:

- Site energy is an actual metric that can be measured and verified by code officials, while source energy is an estimate.

- Site energy information is credible, as it is shown on customers' energy bills on a monthly basis and used in other consensus-based code documents, such as ASHRAE 90.1, use site energy metrics for efficiency requirements.

- DOE uses site energy information in many of its energy efficiency and energy consumption publications, such as the Residential Energy Consumption Survey. DOE uses site energy for its appliance energy efficiency standards program and the FTC uses site energy on the yellow EnergyGuide labels found on consumer appliances. EPA uses site energy to determine if an appliance or home qualifies for the Energy Star program.

- Site energy is reliable, since it can be measured by utilities, consumers, and independent 3 parties. In terms of energy efficiency upgrades, consumers rely on site energy information (amount used by older appliance or equipment compared to new appliance or equipment) to help them make energy efficiency decisions.

- Site energy is replicable, as the units of measurement (kWh, therms, gallons, Btu's) can be used throughout the United States and are familiar to consumers on their monthly energy bills. Source energy is not replicable, as different estimates must be used for different energy sources, and different entities can make different assumptions about upstream production and delivery of different energy sources.

- Site energy is transparent and easy to understand. It can be based on meter readings or DOE test procedures or FTC EnergyGuide labels or Energy Star labels. It is the metric that allows people to easily compare energy efficiency options in the marketplace. It is the metric that allows people to make good economic choices when faced with competitive alternatives.

**Source Energy Estimates**

There are many ways to estimate upstream energy losses. The energy production industry is very dynamic and subject to significant changes. In the United States in 2018, there was a record amounts of natural gas produced from hydraulic fracturing production techniques. In 2018, there was a record amount of oil produced and imported from oil sands production. In 2018, there was a record amount of electricity produced from renewable forms of energy and a record amount of electricity produced by combined-cycle natural gas turbines.

The values that are currently shown should be deleted and not used. The values shown are not consistent with values shown in other published documents. Many documents and articles have been published over the past several years with source energy estimates as shown in the bibliography. The current values in the IECC do not match and cannot be substantiated with any of these published documents.

Different fossil fuels have different upstream source estimates. In the current IECC, all fossil fuels are assumed to have the same multiplier. In other documents, there is a large and statistically significant variation in the upstream estimates that will have a significant impact on energy performance results. As one example, for fuel oil and propane, EPA's Portfolio Manager uses a factor of 1.01 for both, while NREL used estimated values of 1.158 and 1.151, while IGCC 2015 uses 1.19 for fuel oil and 1.15 for propane. The use of 3.16 for electricity is overstated for many parts of the United States and does not account for significant regional differences or the increase in the use of renewable power generation and combined cycle gas.
turbines.

In other publications and web sites, the estimates for electricity are shown on a national basis, a regional basis, or a state by state basis. This is due to the variety of electric generation techniques which have upstream energy losses that can vary by orders of magnitude based on local conditions, regional conditions, physical location, season, month, week, or day, as well as hourly fluctuations in the amount of sunlight or wind speed.

The revisions to the values are based on reports published by the US Energy Information Administration, the US Department of Energy, the US Environmental Protection Agency, national labs, and other public sources of information. It is a technical fact that there are significant differences in terms of upstream estimates for electricity as well as fossil fuels. The new estimates provide more defensible and accurate estimates.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal only provides another option for the simulation used for the performance path.
RE155-19
IECC: R404.1 (IRC N1104.1)

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code
Revise as follows:

R404.1 (IRC N1104.1) Lighting equipment (Mandatory). Not less than 90 percent of the permanently installed lighting fixtures shall contain only high-efficacy lamps. Luminaires shall utilize lamps with an efficacy of at least 65 lumens-per-watt, or have a luminaire efficacy of at least 45 lumens-per-watt.

Proposal # 4453

RE155-19
2018 International Energy Conservation Code

Revise as follows:

R405.3 (IRC N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Data System Prices and Expenditures reports. Code officials shall be permitted to require time-of-use pricing in energy cost calculations.

Exception: The energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

Reason: There is only one metric that consumers are concerned with. That metric is cost. The IECC and its predecessor the model energy code traditionally relied on energy costs to demonstrate compliance. During the 2015 code cycle, this section added the current exception for the use of source energy as an alternative to cost.

Source energy is a relatively complex exercise used to estimate the approximate amount of raw energy consumed in the delivery of energy to ultimate customers. It is not a measurement nor a repeatable calculation across either geography or time.

Among its many limitations, source energy is particularly challenged when dealing with electricity as it treats electricity derived from renewables like solar and wind the same as electricity from an old coal fired generator.

The U.S. Department of Energy recognizes this absurdity – of treating wind the same as coal – and several years ago published a report on the topic. (SEE bibliography).

The overwhelming majority of jurisdictions using the IECC rely on cost.

There is no meaningful reason to keep the exception in the code and it should be removed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal imposes no additional compliance requirements and, therefore, neither increases nor decreases the cost of construction.

Proposal # 4977
2018 International Energy Conservation Code

Add new text as follows:

R405.4 (IRC N1105.4) On-site renewable energy. On-site renewable energy shall be considered as a reduction in energy use of the building.

Reason: The IECC should integrate energy efficiency measures and renewable energy systems. Builders should get credit for what they do. As presented by the Building Technologies Office of the Department of Energy’s 2018 National Energy Codes Conference, according to the U.S. Energy Information Administration’s AEO 2018 report, typical Residential End Uses include Space heating at 24% and Space cooling at 11%, for a combined space heating/cooling at 35% of all Residential Energy End Uses. Water heating accounts for 13.5% of Residential Energy End Uses. These figures illustrate that we have done a very good job of reducing regulated loads, such that unregulated loads now represent greater than 50% of all Residential Energy End Uses. Renewable energy systems can offset not only the unregulated loads, but can also offset the reduced regulated loads.

Compliance measures and compliance paths that focus only on building envelope measures and discourage or penalize renewable energy systems -- or fail to make renewable energy systems attractive to builders as a compliance option -- are focused on solving 35% of the problem. The IECC should encourage the use of energy efficiency plus renewable energy, to solve 100% of the problem.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Installation of an on-site photovoltaic system could increase or decrease the overall first cost of construction.
2018 International Energy Conservation Code

Revise as follows:

R405.4.2 (IRC N1105.4.2) Compliance report. Compliance software tools shall generate a report that documents that the proposed design complies with Section R405.3. A compliance report on the proposed design shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based on the as-built condition of the building shall be submitted to the code official before a certificate of occupancy is issued. Batch sampling of buildings to determine energy code compliance shall only be allowed for stacked multiple-family units. Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. Where the proposed design of a building could be built on different sites where the cardinal orientation of the building on each site is different, compliance of the proposed design for the purposes of the application for the building permit shall be based on the worst-case orientation, worst-case configuration, worst-case building air leakage and worst-case duct leakage. Such worst-case parameters shall be used as inputs to the compliance software for energy analysis.

Reason: The purpose of this code change proposal is to remove confusing and incomplete language from the performance path regarding “batch sampling” of buildings. Section R405.4.2 contains orphan language that implies that batch sampling might be acceptable for stacked multiple family units, but there is no process or criteria for “batch sampling” defined anywhere in the IECC. Before any sort of sampling is allowed, a number of very important questions must be addressed, such as which parts of the building may be batch sampled, what sample size must be collected, what happens in the event of a failure, etc. Although some common voluntary programs permit sampling for certain specified measures, the IECC does not currently allow this practice and should not until these important questions are addressed. Moreover, we are concerned that batch sampling would fail to ensure that every home meets the code, since presumably only some homes would be included in the sampling.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal cleans up excess language that refers to sampling practices that do not currently exist in the IECC.
2018 International Energy Conservation Code

Revise as follows:

R405.4.2 (IRC N1105.4.2) Compliance report. Compliance software tools shall generate a report that documents that the proposed design complies with Section R405.3. A compliance report on the proposed design shall be submitted with the application for the building permit. Upon completion of the building, a confirmed compliance report based on the as-built confirmed condition of the building shall be submitted to the code official before a certificate of occupancy is issued. Batch sampling of buildings to determine energy code compliance shall only be allowed for stacked multiple-family units. Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2.

Where the proposed design of a building could be built on different sites where the cardinal orientation of the building on each site is different, compliance of the proposed design for the purposes of the application for the building permit shall be based on the worst-case orientation, worst-case configuration, worst-case building air leakage and worst-case duct leakage. Such worst-case parameters shall be used as inputs to the compliance software for energy analysis.

R405.4.2.1 (IRC N1105.4.2.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include the following:

1. Building street address, or other building site identification.
2. A statement indicating that the proposed design complies with Section R405.3. The name of the individual performing the analysis and generating the compliance report.
3. An inspection checklist documenting the building component characteristics of the proposed design as indicated in Table R405.5.2(1). The inspection checklist shall show results for both the standard reference design and the proposed design with user inputs to the compliance software to generate the results. The name and version of the compliance software tool.
4. A site-specific energy analysis report that is in compliance with Section R405.3. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. A certificate indicating that the proposed design complies with Section R405.3. The certificate shall document the building components energy specifications that are included in the calculation including, component level insulation R-values or U-factors, assumed duct system and building envelope air leakage testing assumptions, as well as, the type and rated efficiencies of proposed heating, cooling, mechanical ventilation, and service water heating equipment to be installed. If onsite renewable energy systems will be installed the certificate shall report the type and production size of the proposed system.
6. The name and version of the compliance software tool. When a site-specific report is not generated, the proposed design shall be based on the worst-case orientation and configuration of the rated home.

R405.4.2.2 (IRC N1105.4.2.2) Compliance Confirmed compliance report for certificate of occupancy. A confirmed compliance report submitted for obtaining the certificate of occupancy shall be made site and address specific and include the following:

1. Building street address, or other building site identification.
2. A statement indicating that the as-built building complies with Section R405.3. The name of the individual performing the analysis and generating the report.
3. A certificate indicating that the building passes the performance matrix for code compliance and indicating the energy saving features of the building. The name and version of the compliance software tool.
4. A site-specific energy analysis report that is in compliance with Section R405.3. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. The name of the individual performing the analysis and generating the report. A final confirmed certificate indicating compliance based on inspection and statement indicating that the confirmed rated design of the built home complies with Section R405.3. The certificate shall report the energy features that were confirmed to be in the home including component level insulation R-values or U-factors, results from any required duct system and building envelope air leakage testing, as well as the type and rated efficiencies of the heating, cooling, mechanical ventilation, and service water heating equipment installed.
6. The name and version of the compliance software tool. When onsite renewable energy systems have been installed, the certificate shall report the type and production size of the installed system.

R405.4.3 (IRC N1105.4.3) Additional documentation. The code official shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the standard reference design.
2. A certification signed by the builder providing the building component characteristics of the proposed design as given in Table R405.5.2(1).
3. Documentation of the actual values used in the software calculations for the proposed design.
**Reason:** EnergyLogic began to use the Section R405 Simulated Performance alternative and the cost compliance report with our Builder clients to demonstrate energy code compliance when the 2009 IECC was adopted by jurisdictions in the Denver Metro area. We fundamentally defined the process by which the path was used at the time as most jurisdictions did not have experience using it. Use of the pathway took off as we demonstrated that the systems thinking, building science trade-off approach offered tremendous flexibility for how to build a cost-effective code compliant house within a defined structure that ensured both jurisdictional and third-party stringent verification. Therefore, in the 2015 code development cycle we decided to define the process by which the Simulated Performance path was successfully being implemented in Colorado in the body of the IECC to help jurisdictions and builders better understand how to implement the pathway to gain flexibility of choice and trade-off, as well as, to ensure verification that backs it up for compliance.

In the 2021 code adoption cycle, we propose to update the compliance requirements based on what we have learned over the years using the path to help thousands of homes a year demonstrate compliance with the IECC. The changes we propose offer clarification and simplification rather than actually changing what is required. For example, the use of the terms proposed and confirmed to refer to documents that must be part of the document set needed to obtain the building permit and certificate of occupancy is more clearly laid out. In addition, section R405.4.2.1 Compliance report for permit application and section R405.4.2.2 Confirmed compliance report for certificate of occupancy, have been consolidated and reordered to more clearly identify for the jurisdiction having authority the documentation needed to be reviewed to demonstrate compliance.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost implication with these changes to the code. The proposal does not add new requirements but rather cleans up the section for better understanding and use by the jurisdictions and builders that choose it.
RE159-19
IECC: R405.4.2.1

Proponent: Kirk Nagle, City of Aurora, representing Myself (knagle@auroragov.org)

2018 International Energy Conservation Code

Revise as follows:

R405.4.2.1 (IRC N1105.4.2.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include the following:

1. Building street address, or other building site identification.
2. Declare simulated performance path
3. A statement indicating that the proposed design complies with Section R405.3.
4. An inspection checklist documenting the building component characteristics of the proposed design as indicated in Table R405.5.2(1). The inspection checklist shall show results for both the standard reference design and the proposed design with user inputs to the compliance software to generate the results.
5. A site-specific energy analysis report that is in compliance with Section R405.3.
6. The name of the individual performing the analysis and generating the report.
7. The name and version of the compliance software tool.

Reason: This code change is being proposed to clarify the energy path to the code official and the documentation for permit. Many reports do not specify the path that is being proposed and the code official has to contact the applicant to verify the energy path they are intending to use, to comply with the energy code. By providing the method of compliance the code official can focus on the details of the report and this information will expedite the permit process time.

Cost Impact: The code change proposal will increase the cost of construction
This will increase the cost of construction by a very minor amount, adding a data entry to report.
IECC: R402.5 (IRC N1102.5), R405.5.2.1 (IRC N1105.5.2.1) (New)

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants LLC, representing Self (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

R402.1.5 (IRC N1102.1.5) Total UA alternative. Where the total building thermal envelope UA, the sum of U-factor times assembly area, is less than or equal to the total UA resulting from multiplying the U-factors in Table R402.1.4 by the same assembly area as in the proposed building, the building shall be considered to be in compliance with Table R402.1.2. The UA calculation shall be performed using a method consistent with the ASHRAE Handbook of Fundamentals and shall include the thermal bridging effects of framing materials. In addition to UA compliance, the SHGC requirements shall be met.

R402.5 (IRC N1102.5) R402.1.5.1 (IRC N1102.5.1) Maximum fenestration U-factor and SHGC (Mandatory). The area-weighted average maximum fenestration U-factor permitted using tradeoffs from Section R402.1.5 or R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using Section R405 in Climate Zones 1 through 3 shall be 0.50.

Add new text as follows:

R405.5.2.1 (IRC N1105.5.2.1) Maximum fenestration U-factor and SHGC (Mandatory) The area-weighted average maximum fenestration U-factor permitted using Section R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using Section R405 in Climate Zones 1 through 3 shall be 0.50.

Reason: This proposal relocates and apportions the provisions of Section R402.5 to their appropriate locations as they apply specifically to the methodologies therein. No change in stringency or applicability is proposed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification such that a provision “hanging” at the end of Section R402, is appropriately assigned to the “Total UA Alternative” and the “Simulated Performance Alternative,” accordingly. No change to stringency is proposed.
**Proponent**: Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@hatfieldandassociates.com)

**2018 International Energy Conservation Code**

Revise as follows:

### TABLE R405.5.2(1) [IRC N1105.5.2(1)]

**SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS**

<table>
<thead>
<tr>
<th>BUILDING COMPONENT</th>
<th>STANDARD REFERENCE DESIGN</th>
<th>PROPOSED DESIGN</th>

<td>As proposed</td>
<td>As proposed</td>
</tr>
<tr>
<td>U factor: as specified for fenestration in Table R402.1.4.</td>
<td>As proposed</td>
<td>As proposed</td>
</tr>
<tr>
<td>SHGC: as specified for Glazed Fenestration in Table R402.1.2 except for climate zones without an SHGC requirement, the SHGC shall be equal to 0.40.</td>
<td>As proposed</td>
<td>As proposed</td>
</tr>
<tr>
<td>Exterior shade fraction: 0.92 - (0.21 × SHGC for the standard reference design).</td>
<td>Interior shade fraction: 0.92 - (0.21 × SHGC as proposed)</td>
<td></td>
</tr>
</tbody>
</table>

**Skylights**

- skylight area (SYY) where the proposed total fenestration area (A F) is less than 15 percent of the conditioned floor area (CFA). 
  
- skylight area (SYY) where the AF is 15 percent or more of the CFA. 

| Orientation: as proposed | As proposed | As proposed |
| U factor: as specified for Skylights in Table R402.1.2 | As proposed | As proposed |
| SHGC: as specified for Glazed Fenestration and footnote (b) in Table R402.1.2 except for climate zones without an SHGC requirement, the SHGC shall be equal to 0.40. | As proposed | As proposed |
| For the area proposed Skylights equipped and glazed with factory-installed interior shades, the exterior shade fraction is 0.92 - (0.21 × SHGC) as above for the standard reference design. | As proposed, with shades assumed closed 80% of the daylight hours |

Portions of table not shown remain unchanged.
For: 1 square foot = 0.093 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.80 kg/m², 1 gallon (US) = 3.785 L,

\[ C = \left( \frac{F-32}{1.8} \right) \text{, 1 degree} = 0.79 \text{ rad.} \]

a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. Light-transmitting fenestration area includes the area of sash, curbing or other framing elements that are part of the conditioned space enclosure, including light-transmitting assemblies in the walls bounding conditioned basements. For doors where the light-transmitting opening is less than 50 percent of the door area, only the light-transmitting area is included. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing fenestration area:

\[ AF = A_F \times FA \times F. \]

where:

\( AF \) = Total glazing Proposed total fenestration area.

\( A_F \) = Standard reference design total glazing fenestration area.

\( FA = \frac{(Above-grade \text{ thermal boundary gross wall area}) + (0.5 \times \text{ below-grade boundary wall area})}{(above-grade thermal boundary wall area + common wall area)} \)

\( F = \frac{(above-grade \text{ thermal boundary wall area})}{(above-grade \text{ thermal boundary wall area} + \text{ common wall area})} \) or 0.56, whichever is greater.
Reason: The IECC residential simulated energy performance analysis standard reference design specification table has historically included skylight area in the "Glazing" row, as reflected in the 2012 IECC:
Footnote (a) clearly refers to “the area of ... curbing ...” in the definition of “Glazing”, which is only germane to skylights on a roof. The commentary versions of the 2012 and prior editions reinforce this intent to cover skylight area in the glazing row for the reference design.

The approval of RE173-13 upset the applecart for skylights in the 2015 IECC. The proponent later acknowledged at 2018 IECC code hearings that it was not intentional, but the two major elements of that change took away the only place for skylights to be included in the reference design:

- “Glazing” was changed to “Vertical fenestration other than opaque doors”
- Footnote (a) was inexplicably deleted, rather than redefine fenestration area calculation rules.

Our proposed changes to Table R405.5.2(1) reinstate the allowance to include skylight area in the Standard Reference Design as part of the Total Fenestration Area when they are part of the proposed design, by adding the following:

1. Provisions for skylight area, U-factor and shading that mirror the Vertical Fenestration provisions, wherever practical.
2. Provisions for skylight SHGC that mirror those for Vertical Fenestration, with the addition of a reference to Footnote (b) of Table R402.1.2 specific to skylight SHGC.
3. Provisions for skylight orientation based upon “As Proposed”. Typically, skylight installation in residential construction is not able to be equally distributed to all four cardinal compass orientations, as assumed for vertical fenestration under the Simulated Performance Alternative provisions.
4. Suitable interior shading provisions that are used when any of the proposed skylights are rated products that include integral interior shading.

This proposal also includes the following coordinating changes:

1. In footnote (h), reference to “glazing area” is replaced by “fenestration area”, while restoring needed clarifying language from old footnote (a) defining what is included in calculating the area of various fenestration products regardless of slope or position on the envelope.
2. Provisions are added to reduce the vertical fenestration area and skylight area proportionally for the Standard Reference Design, whenever any skylight area is proposed and total fenestration area equals or exceeds 15% of conditioned floor area.
Bibliography: 2012 IECC, Table R405.5.2(1)

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The code change proposal will not increase the cost of construction but rather reinstates language that was unintentionally removed.
TABLE R405.5.2(1) [IRC N1105.5.2(1)]

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L.

\(°C = (°F-32)/1.8\), 1 degree = 0.79 rad.

- a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.
- c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.
- d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.
- e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.
- f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.
- g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.
- h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[ AF = A_s \times FA \times F \]

where:

- AF = area factor
- A_s = solar fraction
- FA = air fraction
- F = infiltration factor
AF = Total glazing area.

A_r = Standard reference design total glazing area.

FA = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 × below-grade boundary wall area).

F = (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.

and where:

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.

Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.

Below-grade boundary wall is any thermal boundary wall in soil contact.

Common wall area is the area of walls shared with an adjoining dwelling unit.

L and CFA are in the same units.

i. The factor for the compactness of the hot water distribution system is the ratio of the area of the rectangle that bounds the source of hot water and the fixtures that it serves (the “hot water rectangle”) divided by the floor area of the dwelling.

1. Sources of hot water include water heaters, or in multi-family buildings with central water heating systems, circulation loops or electric heat traced pipes.

2. The hot water rectangle shall include the source of hot water and the points of termination of all hot water fixture supply piping.

3. The hot water rectangle shall be shown on the floor plans and the area shall be computed to the nearest square foot.

4. Where there is more than one water heater and each water heater serves different plumbing fixtures and appliances, it is permissible to establish a separate hot water rectangle for each hot water distribution system and add the area of these rectangles together to determine the Compactness Ratio.

5. The basement or attic shall be counted as a story when it contains the water heater.

6. Compliance shall be demonstrated by providing a drawing on the plans that shows the hot water distribution system rectangle(s), comparing the area of the rectangle(s) to the area of the dwelling and identifying the appropriate compactness ratio and HWDS factor.

Reason: The purpose of this proposal is to encourage the architectural compactness of the location of the wet rooms and the water heaters that serve them. Wet rooms contain plumbing fixtures and appliances. They are often located far apart from each other and from the water heater that serves them. The long distances between them results in long and often larger diameter piping runs. These piping runs need to be cleared of the ambient temperature water in them before hot water can arrive. This addition time is often annoying to consumers and the waste of water and energy while waiting can be costly.

If the architect locates the wet rooms closer together and to the water heater that serves them, it makes it possible for the pipe runs to be shorter and often of a smaller diameter. The reduced volume of ambient temperature water clears out more quickly, increasing customer satisfaction. In addition, the associated water and energy waste is less, reducing operating costs.

Benefits:

1. This proposal provides a credit when the wet rooms are located close to each other. There is no penalty for not taking advantage of the credit.

2. The builder still has flexibility over where to put the wet rooms and the water heater(s). It is possible to take advantage of the credit in larger dwellings by having a water heater associated with each group of wet rooms.

3. The credit can be applied to single and multi-family dwellings. Where the dwelling has its own water heater, the calculation is done with the water heater as the source of hot water. In multi-family buildings with central water heating systems, the calculation is done from where the branch off the circulation loop or heat traced trunk line to the apartment begins.

4. Compliance can be demonstrated on the drawings and verified during plan check.

How to Implement the Proposed Credit for Architectural Compactness
Locate the water heater and the hot water fixtures and appliances.
2. Draw a rectangle through the center line of the water heater and the plumbing walls next to the hot water fixtures and appliances.
3. Calculate the area of this rectangle.
4. Divide this area by the conditioned floor area of the home to get the Compactness Ratio.
5. Determine if a credit can be taken and how large it can be.

1-Story, 3 Bedroom, 2 Bath
1. Conditioned floor space: 1,147 SF
2. Hot water system rectangle: 35x23 = 820 SF
3. Compactness Ratio: 820/1,147 = 72%
4. HWDS Factor for 1-Story: 0.0

Habitat for Humanity, Stockton CA

Plumbing wall goes around the middle bathroom

Bounded area is roughly 50 sq ft

Plumbing wall is roughly 22 feet long
1-Story, 3 Bedroom, 2 Bath
1. Same builder, similar size dwelling.
2. Different floor plan with wet rooms located close to each other.
3. Move the water heater very close to the wet rooms.
4. Conditioned floor space: 1,223 SF
5. Hot water system rectangle: 8 x 9 = 72 SF
6. Compactness Ratio: 72/1,223 = 5.9%
7. HWDS Factor for 1-Story: 0.15

2 story, 4 bedrooms, 3 bath 2625 sq ft Meritage Homes Bakersfield

2-Story, 4 Br/3 Ba, 2,625 sq ft
Compactness Ratio: 0.632/0.705 = 0.9
HWDS Factor: 0.3
Show the rectangle on all floors with hot water uses.

2-Story above basement, 4Br / 3Ba, 2,709 sq ft
Compactness Ratio: 0.825/0.709 = 1.2
HWDS Factor: 0.15
Show the rectangle on all floors with hot water uses.

Camden, Chula Vista - Camden Sierra at Otay Ranch, 1A
Cost Impact: The code change proposal will not increase or decrease the cost of construction.
Locating the wet rooms closer together and to the water heater that serves them reduces the cost of installing the hot water distribution system. Typical dwellings have very large compactness ratios, often much larger than the 60% cut off point for obtaining this credit. Reducing the ratio from 75% to 20% in a 1-story single family detached dwelling can reduce the first costs by $1,000-2,000.

The reason we are not claiming a cost reduction is that there will be some cost for the architect to (re)design a given nominal floor plan to take advantage of the credit. For production builders this cost can be amortized over many homes, so at some point, it will cost less to build all future houses with this floor plan.

Another reason we are not claiming it will reduce construction costs is that if the builder chooses to take advantage of the credit by installing more than one water heater so that each water heater is close to the wet rooms it serves, there will be a cost for the second water heater. Some, perhaps all of the extra cost due to the additional water heater(s) will be offset by the reduced costs of the hot water distribution system. However, multiple water heaters are often installed in larger dwellings and where this is already the case, the marginal cost of locating closer to groups of wet rooms is likely to be small compared to the savings in the hot water distribution system. And in dwellings where a circulation loop was planned in order to get hot water to fixtures quickly, installing a second water heater close each group of wet rooms can eliminate the need for and costs of the circulation loop.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

**Reason:** This proposal will revise the formula in Table R405.5.2(1) that specifies the volume of domestic hot water usage in the residential performance path. This formula has remained unchanged in the code since the very first edition of the IECC in 1998, even as residential hot water usage declined over this period. The proposal will reduce the stipulated daily volume of service hot water use by 15%. For example, under the current formula, the daily hot water use of a 3-bedroom home is 60 gallons, while under the proposal a 3-bedroom home would be assumed to draw 51 gallons of hot water.

The formula currently applies to both the standard reference design and the builder's proposed design, and the proposal does not change this parity. Nor does the proposal change any other aspect of DHW system design or water heater selection. By overestimating hot water usage, the current formula overstates the relative share of hot water energy use compared with all other energy uses included in the performance path analysis. Revising this formula will make the characterization of hot water energy use more realistic, and acknowledge the progress made in improving the efficiency of hot water use over the last 20 years.

**Background**

The current formula for domestic hot water use has remained unchanged since the first edition of the IECC in 1998. It appears to have had its origin in the last CABO energy code development process of 1995-96, which produced a draft text that became the ICC’s template for the first edition of the IECC. (ICC Staff) In the 20+ years since the adoption of this formula, the drivers of domestic hot water usage have changed, in large part due to federal efficiency standards that save energy by reducing hot water use.

The US Department of Energy recognized that previous assumptions about residential hot water use were too high during the development of the current water heater efficiency standard adopted in 2010. (DOE STD) In the course of developing this standard, DOE reviewed the hot water model developed during the previous rulemaking that concluded in 2001 and was based on 1990s-era appliance performance. For its new analysis, DOE developed a new set of draw patterns based on field data assembled in a Lawrence Berkeley National Laboratory report. (Lutz et al) The LBNL report incorporated data collected by 10 independent studies involving 142 houses averaging 3.04 occupants, and 1.5 million hot water draws. The LBNL report found an average daily median volume of hot water use among its sample of 50.6 gallons.

In its 2009 Technical Support Document (DOE TSD) for the 2010 water heater standard, DOE noted that --
The Hot Water Draw Model incorporates the parameters for clothes washer and dishwasher hot water use. These parameters reflect assumptions about clothes washer and dishwasher water use as they existed in the 1990s. Since that time, there has been a considerable change to clothes washer and dishwasher technology that has resulted in lower hot water use. In particular, updated Federal energy conservation standards for clothes washers that became effective in 2007 and for dishwashers that will become effective in 2010 have a significant impact on clothes washer and dishwasher hot water use.

The baseline water use for clothes washers in the 1990s was 39.2 gallons/cycle and the water use calculated based on the 2007 standard is 21.0 gallons/cycle. The baseline water use for dishwashers in the 1990s was 8.2 gallons/cycle and the water use calculated based on the 2010 standard is 6.5 gallons/cycle. Therefore, DOE updated the draw model to account for the reduced hot water use by adjusting the dishwasher and clothes washer water use variables to account for the new standards. The results are shown in Table 7-B.3.1. For example, the impact on gas-fired storage water heaters was a reduction of the average daily water use by 10.7 percent.

In the TSD's accompanying table, the results of these revisions to the draw model are shown for four types of water heater (gas-fired storage, electric, oil-fired, and gas instantaneous), with water use reductions for all of them clustering close to the average reduction of 10.1 percent for the group.

DOE took further note in the reduction in residential hot water use during the development of a revised test procedure for hot water heaters adopted in 2014. In its 2013 NOPR on the revised test procedure (DOE TP NOPR), DOE referred once again to the LBNL report, stating --

"LBNL found that typical usage in North America is characterized by . . . a smaller volume of water per day than is currently prescribed in the residential test method . . . ."

More recently, the Water Research Foundation's "Residential End Use of Water, Version 2" (REUWS 2) report published in 2016 documented substantial reductions in residential indoor water use compared with a similar assessment in 1999. Additionally, REUWS 2 specifically collected data on hot water use in a subset of its sampled homes (94 homes in 10 cities), and found an average use of 45.5 gallons per household per day. The median number of bedrooms in this sample was 3.0, which squares with the US national median bedroom count of 3.0 recorded by the US Census in 2015. (CENSUS)

Thus, LBNL's assessment published in 2010 found a median draw of 50.6 gallons per day and encouraged DOE to reduce the draw volumes in the hot water model for the 2010 efficiency standard as well as the draw volumes in the water heater test procedure revised in 2014. REUWS 2 corroborated the downward trend found by LBNL with a median daily draw of 45.5 gallons. In light of the foundational role of the LBNL report in the daily draw volumes used in both the current water heater standard and the water heater test procedure, this proposal achieves alignment between the data relied upon by DOE and the water usage stipulated for the performance path analysis in Table R405.5.2(1) by reducing the constants in the formula by 15%.

**Effects of Proposal**

The effect of the revision of the formula on the assumed daily hot water use in homes of varying numbers of bedrooms can be seen in the following table.

**Service Hot Water Daily Usage for Reference Design and Proposed Design in Energy Performance Analysis**

<table>
<thead>
<tr>
<th>Home Bedroom Count</th>
<th>Current Formula</th>
<th>Revised Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 Bedroom Home</td>
<td>50 gal/day</td>
<td>42.5 gal/day</td>
</tr>
<tr>
<td>3 Bedroom Home</td>
<td>60 gal/day</td>
<td>51.0 gal/day</td>
</tr>
<tr>
<td>4 Bedroom Home</td>
<td>70 gal/day</td>
<td>59.5 gal/day</td>
</tr>
<tr>
<td>5 Bedroom Home</td>
<td>80 gal/day</td>
<td>68.0 gal/day</td>
</tr>
</tbody>
</table>

It should be remembered that the daily hot water usage established by the formula in Table R405.5.2(1) does NOT serve as a performance requirement for appliances or fixtures in the home. Rather, it simply provides the deemed value of daily water use upon which the energy consumption of various equipment choices made by the builder can be quantified and brought into the calculation of the annual energy cost (or source energy consumption) of the whole building. The revision to the formula in this proposal would make the values used for hot water energy consumption in the performance analysis more reflective of recent residential water use patterns, and thus more realistic.

**Bibliography:**

ICC Staff, Personal communication in response to a code history question, Fred Grable e-mail, Dec. 17, 2018.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal has no impact on the cost of construction. It revises the voluntary residential performance path by adjusting the volume of daily hot water usage assumed for both the reference design and the builder’s proposed design. It contains no requirement that would raise the cost of water heating equipment.

</tr>
<tr>
<td>Untested distribution systems entirely located in conditioned space</td>
<td>0.88</td>
<td>1</td>
</tr>
<tr>
<td>Proposed “reduced leakage” when the installed air distribution system is located entirely within the continuous air barrier assembly and building thermal envelope’s defined conditioned space as verified through inspection before drywall has been installed</td>
<td>0.96</td>
<td>—</td>
</tr>
<tr>
<td>“Ductless”Ductless” systems</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

For SI: 1 cubic foot per minute = 0.47 L/s, 1 square foot = 0.093 m², 1 pound per square inch = 6895 Pa, 1 inch water gauge = 1250 Pa.

a. Default values in this table are for untested distribution systems, which must still meet minimum requirements for duct system insulation.

b. Hydronic systems shall mean those systems that distribute heating and cooling energy directly to individual spaces using liquids pumped through closed-loop piping and that do not depend on ducted, forced airflow to maintain space temperatures.

c. Entire system in conditioned space shall mean that no component of the distribution system, including the air-handler unit, is located outside of the conditioned space.

d. Ductless systems shall be allowed to have forced airflow across a coil but shall not have any ducted airflow external to the manufacturer’s air-handler enclosure.

e. For homes with thermal distribution systems documented through visual verification at a rough stage of construction before drywall has been installed to be entirely within the continuous air barrier assembly and building thermal envelope of conditioned space, including all ducts and the manufacturer’s air handler enclosure, a DSE of 0.96 shall be applied to the Proposed Design without the requirement to conduct duct leakage testing. Alternatively, Total leakage of not greater than 4 cfm per 100 ft² of conditioned floor area at a pressure difference of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer’s air handler enclosure, shall be deemed to meet this requirement without measurement of leakage to outdoors.

Reason: The energy penalty or loss of duct leakage is different for duct systems that are located inside or outside of the buildings continuous air barrier assembly. The 2006 IECC recognized this in the IECC table titled, “DEFAULT DISTRIBUTION SYSTEM EFFICIENCIES FOR PROPOSED DESIGNS” that accompanies the proposed and reference home table for the Simulated Performance Alternative path. At some point this was removed, but since the energy code only requires testing for Total duct leakage it makes sense to add it back in. If the entirety of the duct system including the air handler cabinet is confirmed to be located inside conditioned space as defined by the continuous air barrier and thermal envelope assemblies, then the likelihood of the system leaking to the outdoors is little. Therefore, the energy loss of duct leakage to outside would also be little. If testing is not performed for duct leakage to outside a small penalty should be assessed which this proposal provides. If, alternatively, a total duct leakage test is performed then the total duct leakage test results can be used in the modeling for leakage to outside which this proposal also allows as long at the total duct leakage number in not greater than 4 CFM per 100 ft² of conditioned floor area.

This proposal, although allowing verified HVAC duct systems not to be tested for duct leakage to outdoors, does assess a DSE of 0.96 which equates to a 4% energy loss for the system. Thus, if needed for compliance or to allow designed tradeoffs to be calculated in the software, duct leakage could be tested to demonstrate a reduced leakage level below this rate.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

In most cases this proposal would lower the cost of 3rd party compliance with the IECC as a single total duct leakage test could be used to document location and leakage of the duct system allowing for no testing to occur to quantify duct leakage to the outdoors

Proposal # 5280
**2018 International Energy Conservation Code**

Revise as follows:

**TABLE R405.5.2(1), [IRC N1105.5.2(1)]**

<td>As proposed Use, in units of gal/day = 30 + (10 × N&lt;br&gt;) where: N&lt;br&gt; = number of bedrooms.</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

°C = (°F-32)/1.8, 1 degree = 0.79 rad.

a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[ AF = A_s \times FA \times F \]

where:

\( AF \) = Total glazing area.

\( A_s \) = Standard reference design total glazing area.

\( FA \) = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 × below-grade boundary wall area).

\( F \) = (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.
and where:

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.

Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.

Below-grade boundary wall is any thermal boundary wall in soil contact.

Common wall area is the area of walls shared with an adjoining dwelling unit.

L and CFA are in the same units.

**Reason:** The method of test for water heater efficiency was updated in 10 CFR §430.32 (2018). The proposed changes to the service water heating row in the performance table reflect these changes.

The two deleted footnotes referred to in this row do not appear to be related to water heating.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

The updates to the table are the same in both the standard reference and the proposed columns. No new requirements are imposed on construction practices, hence no changes to the cost of construction are expected.

Proposal # 5287

<td>Air exchange rate</td>
<td>The air leakage rate at a pressure of 0.2 inch w.g. (50 Pa) shall be Climate Zones 1 and 2: 5 air changes per hour for spaces with ducted heating and cooling systems; 4 air changes per hour for non-ducted heating and cooling systems. Climate Zones 3 through 8: 3 air changes per hour for spaces with ducted heating and cooling systems; 2 air changes per hour for non-ducted heating and cooling systems. The mechanical ventilation rate shall be in addition to the air leakage rate and shall be the same as in the proposed design, but not greater than $0.01 \times CFA + 7.5 \times (N + 1)$ where: $CFA$ = conditioned floor area, $\text{ft}^2$. $N$ = number of bedrooms. Energy recovery shall not be assumed for mechanical ventilation.</td>
<td>The measured air exchange rate. The mechanical ventilation rate shall be in addition to the air leakage rate and shall be as proposed.</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.93 $\text{m}^2$, 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

$^a$ C = ($^\circ$F - 32)/1.8, 1 degree = 0.79 rad.

a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

**Reason:** Energy losses through ductwork are recognized as significant and come from two distinct sources; air lost through ductwork to the outside and, separately, induced infiltration/exfiltration caused by duct pressurization. Air lost to the outside is self-explanatory and is, in fact, already recognized by the 2015 IECC (and earlier versions) in Table R405.5.2(2) where distribution system efficiency is discounted under certain common conditions. In addition, there is growing recognition that ductwork design can have a significant impact on infiltration/exfiltration. On this basis, a reasonable person could conclude that, all other things being held constant, a non-ducted ERH systems would consume less energy than a ducted electric furnace. This proposal recognized the reduced infiltration impact of using non-ducted space heating.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal imposes no additional requirement and, thus, does not add costs.

Proposal # 4079
2018 International Energy Conservation Code

<td>As proposed</td>
</tr>
</tbody>
</table>

For SI: 1 square foot = 0.093 m\(^2\), 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m\(^2\), 1 gallon (US) = 3.785 L,

\(^{a}\) C = (\(^\circ\) F - 32)/1.8, 1 degree = 0.79 rad.

\(^{b}\) Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

**Reason:** ASHRAE 62.2 is the ANSI consensus standard for determining the ventilation flow rates needed to provide minimum acceptable indoor air quality. It is well known that ASHRAE 62.2 ventilation rates can be higher than IRC ventilation rates, especially for tight dwelling units. As homes get tighter, ASHRAE's rates go up. On the other hand, the IRC's rates are constant regardless of how tight a dwelling unit is; a home with an air tightness of 0.5 ACH50 would require the same amount of ventilation as a home with an air tightness of 5 ACH50, resulting in drastically fewer air changes for the tight home and putting the tight home at risk for poor indoor air quality. When using the performance path to comply with the IECC (i.e., Table R405.5.2(1)), a high performance home with a tight dwelling unit is penalized for following adjusting its ventilation rate upward to
compensate for the decrease in infiltration air changes. This table should not penalize homes for maintaining minimum IAQ in accordance with ANSI consensus standards. As such, the flow rate for the reference home should still be equal to the proposed design homes flow rate, but should also be capped at the ASHRAE 62.2 rate. Under this scenario, flow rates for the proposed design exceeding the minimum ASHRAE flow rate (based on the simplified compliance path equation of 0.3*CFA + 7.5*(Nbr+1)) will still be penalized for additional energy used.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal has no bearing on the cost of construction as it does not require builders to size ventilation systems differently. It simply permits builders to not be penalized if electing to set ventilation air flow rates equal to that established within the ANSI consensus standard for minimum acceptable indoor air quality.
**RE170-19**

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

°C = (°F-32)/1.8, 1 degree = 0.79 rad.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

**Reason:**

As it is written, Table R405.5.2(1) requires a modeler to assume a heat pump system whenever a designer proposes to use "... other than electric heating without a heat pump," i.e., electric resistance or electric radiant heating (collectively "ERH") in a new residence. While perhaps serving a valuable function in some fashion (elimination of gaming where a modeler assumes an electric furnace for the reference house and then proposes a heat pump allowing a less stringent envelope), the limitation on use of ERH in the modeling is overly restrictive. ERH is available in many different applications and the performance characteristics of non-ducted ERH are very different from the performance characteristics of ducted heating systems, whether fueled by electricity, gas, or any other fuel. In addition to no duct energy losses, non-ducted ERH also enjoys significant energy savings from zoning. This proposal attempts to preserve the benefit of eliminating gaming while still recognizing the energy savings potential of non-ducted ERH. In addition, this proposal cites the heat pump specific provisions of the IECC commercial provisions rather than simply citing the commercial chapter.

**Substantiation:**

ERH is available in a number of different configurations, including electric furnace, baseboard, radiant, energy storage and PTAC. For purposes of this proposal, however, only non-ducted ERH is being considered. The operational and energy consumption characteristics of ducted vs. non-ducted ERH are significant and are at the core of the rationale behind this code change proposal. Unfortunately, ducted and non-ducted ERH systems are often grouped together (as they are in the existing code language).

Language like that found currently in Table R405.5.2(1) that requires a modeler to assume a heat pump in the reference house, even if the designer intends to use electric baseboard heating in the proposed house, has been in the IECC for many years. The justification cited historically for that modeling limitation is:

- That modelers will game the system by assuming ERH in the reference house but a heat pump in the proposed house, thereby allowing a less stringent envelope, and/or

- That a heat pump will consume on the order of half the energy of an electric furnace installed in the same house so the code should discourage designers from specifying ERH and instead should specify a heat pump.

With respect to the former of these justifications, the current language requiring the same equipment to be modeled in both the reference and the proposed designs denies any opportunity to game the system as described above.

That leaves the latter as the sole justification for the modeling restriction against using electric resistance heating as the equipment assumption in the
reference house. To some extent, this seems appropriate. If, for instance, in a heating dominated climate, a designer is proposing to install a ducted electric furnace with central air-conditioning, then incenting that designer to use a heat pump instead would probably be expected to save significant amounts of energy at a relatively modest cost.

But there are significant operational and energy consumption characteristics that distinguish **ducted from non-ducted** ERH as described in more detail below.

**Ducted vs. non-ducted heating systems.** Non-ducted ERH has significantly different operational and energy consumption characteristics from ducted heating systems.

**Fan Power.** Numerous studies over the last decade have identified furnace fan energy usage as more significant than before believed. As a result, the U.S. Department of Energy has initiated a rulemaking to establish a test procedure for determining furnace fan energy. Likewise, the Environmental Protection Agency now has an Energy Star rating for efficient furnace fans. Of course, non-ducted ERH like baseboard or radiant doesn’t use a fan. On this basis, a reasonable person could conclude that, all other things being held constant, a non-ducted heating system (without a fan) would consume less energy than a ducted system with a fan using the same technology (gas, oil, electric resistance, etc.).

**Duct loss and fan induced infiltration.** Energy losses through ductwork are recognized as significant and come from two distinct sources; air lost through ductwork to the outside and induced infiltration/exfiltration caused by duct pressurization. Air lost to the outside is self-explanatory and is, in fact, already recognized by the 2012 IECC (and earlier versions) in Table R405.5.2(2) where distribution system efficiency is discounted under certain common conditions. In addition, there is growing recognition that ductwork design can have a significant impact on infiltration/exfiltration. On this basis, a reasonable person could conclude that, all other things being held constant, a non-ducted ERH system would consume less energy than a ducted electric furnace.

**Zoning.** Ducted, central heating, whether it be a ducted heat pump, electric furnace, gas furnace or other, is designed to serve large areas, most often an entire house. Non-ducted ERH, on the other hand, generally divides a house up into numerous independently controlled zones. The energy efficiency benefits of zoning are well documented as it allows users to heat only those areas that are occupied resulting in significant savings. On this basis, a reasonable person could conclude that, all other things being held constant, a zoned, non-ducted heating system would consume less energy than a ducted heating system using the same technology (gas, oil, electric resistance, etc.).

**Additional considerations.** Few people would argue that, at the margin, a zoned, non-ducted ERH would be expected to consume fewer btu’s over the course of a winter than a ducted electric furnace. In addition to these operational differences, however, (no fan energy, no duct losses, benefits of zoning), there are other reasons why ERH should be treated differently from ducted heating systems as noted below.

**Cooling.** There are still a non-trivial amount of new homes built in the United States every year without central cooling. According to the EIA, over 800,000 new homes were built between 2000 and 2009 without air-conditioning. A recent study in the Pacific Northwest revealed a relationship between increased use of cooling energy in homes that use heat pumps vis-à-vis electric furnaces. While there are a number of potential explanations, at least one explanation is that people using non-ducted ERH consciously decline to install air conditioning. Thus, incenting the use of heat pumps over ERH may have the unintended result of increasing summer cooling energy.

**Cooling dominated climate.** In cooling dominated climates, with relatively few heating degree days (DOE Climate Zones 1 & 2), driving a builder to use a heat pump which would save relatively little – if any – heating energy due to the warm climate would result in fewer dollars for that builder to spend on other things like more attic insulation or higher SEER air-conditioning – something that would actually result in energy savings.

Non-ducted ERH has significantly different operating characteristics than ducted heating systems.

With respect to the assumption that a heat pump system will consume less than half the btus’s of an electric resistance heating system because the heat pump has a COP of 2 or better, this assumption may be valid for a comparison between a ducted heat pump and a ducted electric resistance furnace, but it not accurate for non-ducted, zoned ERH (See Note 1 below)

In a study conducted by the National Association of Home Builders Research Center for the U.S. Department of Energy, an occupied house in the Washington, D.C. area was monitored for performance over a winter. The house contained three distinct heating systems; central electric heat pump, electric radiant heat, and electric baseboard heat. After the data was weather normalized, it revealed that, under actual homeowner controlled conditions, the electric radiant system used 33% percent less energy than the heat pump system and 52% less than the electric baseboard system. Thus, the heat pump only saved about 28% the energy consumed by the electric baseboard system.

Heat pumps are a great option when a person wants a central, ducted heating and cooling system but they having different operating characteristics from a non-ducted heating system.

**Note 1.** Recent field data from a large survey of homes suggests that the actual (vs. theoretical) relationship may not be as well understood as previously believed. See study at http://www.nwcouncil.org/energy/rtf/meetings/2009/04/Draft%202008%20NEEM%20Study_040608.pdf (p. 21) where observed heat pump energy savings were far short of expectations and the report said
"For the heat pump cases, however, the apparent similarity between electric resistance and heat pump systems suggest minimal savings for the more efficient heat pump option. Some form of behavioral—takeback—poor heat pump installations or increased summer cooling load for heat pumps vis-à-vis resistance houses seem the likeliest explanations. Given that a number of the zone 1 sites (e.g.: Medford, Oregon; Yakima, Washington; and The Dalles, Oregon), have cooling climates, the latter seems plausible. A possible alternate contributing explanation is that these heat pump units do not in fact achieve an average COP of as much as 2 under actual operating conditions. Field notes from heat pump cases in the Oregon sample (a high percentage of heat pumps) mentioned occupants who complained about a lack of comfort to their heating contractor and were told by their heating contractors to switch the heat pumps to run in electric resistance heating mode."

Bibliography: Study of manufactured housing in the Pacific Northwest,

For an Alliance to Save Energy video on the benefits of zoning see http://www.energynow.com/video/2011/11/16/home-efficiency-tips-heating-and-cooling-zones where the moderator quotes the Department of Energy as saying that zoning can save up to 30% on home heating and cooling bills.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal imposes no additional requirement and, thus, does not add costs.

</table>

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

° C = (° F-32)/1.8, 1 degree = 0.79 rad.

Reason: Duct location plays a significant role in the energy performance of the HVAC distribution system yet the location has not been specifically called out in the specification for the standard reference and proposed design. Most software that I am aware of that model for compliance using the Simulated Performance path interpret the model to include duct location so this addition to the language of the specification justifies that modeling interpretation.

In addition, the modeling software models the energy penalty associated with duct leakage to outside not total duct leakage. The additional language of this proposal makes it clear which duct leakage test is being used in the modeling.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost impact to the language clarification that is offered through the adoption of this proposal.

</table>

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L, C = (°F - 32)/1.8, 1 degree = 0.79 rad.

a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[
AF = A_s \times FA \times F
\]

where:

\( AF = \) Total glazing area.

\( A_s = \) Standard reference design total glazing area.

\( FA = \) (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 \times below-grade boundary wall area).

\( F = \) (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is smaller.
greater.

and where:

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.

Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.

Below-grade boundary wall is any thermal boundary wall in soil contact.

Common wall area is the area of walls shared with an adjoining dwelling unit.

$L$ and $CFA$ are in the same units.

**Reason:** Addressing latent loads associated with ventilation air can require a large amount of energy, especially in humid climates. Specification of energy recovery ventilators (ERVs) for mechanical ventilation can reduce the latent loads associated with ventilation air; however, there is no way to account for the ability of ERVs to reduce latent loads of ventilation air within Table N1105.5.2(1). This proposal establishes a method for accounting for the latent energy savings of ERVs where specified in the proposed design. A target of 60% relative humidity is typical for the upper bound in residential applications; above this level, there can be problems associated with moisture and condensation, negatively affecting building durability and indoor air quality; using a setpoint below this level can significantly increase energy use of the dehumidifier (and perhaps over-emphasize the benefit of ERVs in typical residential applications). The energy factor used for the dehumidifier (1.77 liters/kWh) is identical to the minimum value listed in the code of federal regulations (10 CFR 430.32) for typical whole-home dehumidifiers (i.e., those with a case volume < 8 ft³).

**Cost Impact:** The code change proposal will decrease the cost of construction

Where ERVs are specified, this measure can reduce the cost of construction by reducing the annual energy costs associated with the proposed design and permitting more flexibility in design.

For SI: 1 square foot = 0.93 m$^2$, 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m$^2$, 1 gallon (US) = 3.785 L,

*C = (°F-32)/1.8, 1 degree = 0.79 rad.*

**Reason:** The design of the mechanical ventilation system can have a large impact on the energy performance of a dwelling. This impact is not included in the Performance Path however and as a result there is no difference in the between using a 20 watt exhaust fan or 600 watt AHU to deliver 50 CFM of air. As the minimum efficiencies of mechanical ventilation systems are not governed by NAECA and efficiency floors are already included in the IECC in R403.6 it seems reasonable to include potential efficiency gains based on design selection in the Performance Path similar to the Air exchange rate and Thermal distribution systems.

**Cost Impact:** The code change proposal will decrease the cost of construction
By allowing mechanical ventilation systems to be modeled appropriately, correct (and smaller) equipment sizes will lower construction costs

Proposal # 5560

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L.

$^a$ °C = (°F-32)/1.8, 1 degree = 0.79 rad.
a. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[ AF = A_s \times FA \times F \]

where:

- \( AF \) = Total glazing area.
- \( A_s \) = Standard reference design total glazing area.
- \( FA \) = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 \times below-grade boundary wall area).
- \( F \) = (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.

and where:

- Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.
- Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.
- Below-grade boundary wall is any thermal boundary wall in soil contact.
- Common wall area is the area of walls shared with an adjoining dwelling unit.

\( L \) and \( CFA \) are in the same units.

**Reason:** This proposal includes energy neutral trade-offs for equipment efficiency, but also includes a reasonable thermal envelope through the addition of a UA backstop. The ERI compliance path reintroduced equipment efficiencies as part of energy neutral trade-offs and also included a new concept of requiring a reasonable minimum thermal envelope in a performance-type analysis. This proposal takes this “reasonable envelope” concept and applies it to the Simulated Performance Alternative (Section 405). However, rather than pointing to the prescriptive tables in a previous version of the IECC as is done in the ERI, the thermal backstop becomes a percent UA trade-off. The UA calculation will be performed internally with the compliance software. It is an easy calculation as all the necessary information is already entered (component area and U-factors/R-values). This should not be problematic as it is already done for windows. Energy neutral equipment trade-offs had been in the IECC residential section for years. Equipment trade-offs are included in every other energy code/standard and above code program in the United States: IECC Commercial
ASHRAE 90.1

IgCC

National Green Building Standard

LEED Commercial

LEED for Homes

Energy Star

RESNET

The fear that has been spread with bringing back equipment trade-offs is that the envelope will be substandard. The proposed UA trade-off of 15% considered a reasonable envelope backstop. Quite often, the use of this high-efficiency equipment provides a more cost-effective solution to achieve code compliance. Eliminating this ability discourages the concept of the "house as a system" approach, which is a cornerstone of building science.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This will help achieve higher performing dwellings while adding flexibility.
Proponent: Craig Conner, representing self (craig.conner@mac.com)

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the with the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design. The minimum uniform energy factor shall be selected based on the Medium draw pattern found in Subpart C of 10 CFR 430.32 (2021). This water heater shall be used for the proposed water heater in the case of a proposed design without a proposed water heater.

Add new standard(s) as follows:

Reason: Equipment efficiency is a key part of home energy efficiency. This proposal restores equipment efficiency to the performance calculation. This proposal also corrects a long-standing error in the code, that of citing “prevailing federal minimum efficiency”.

The code’s use of “prevailing federal minimum efficiency” is inappropriate and may hamper adoption. Yes, this language has been used for some time and is currently in three existing table footnotes, footnotes “e”, “f” and “g”. However, “prevailing” creates a problem. When states, counties and cities adopt laws, they are obligated to make the exact content of the law available to the public. When the ‘prevailing’ federal minimum efficiency changes; the jurisdiction’s code also changes automatically. Changing the “prevailing” standard without any jurisdictional process means another body, which is not the legislative body of the jurisdiction, changes the laws within the jurisdiction without any public hearing or vote by the local legislative body. This is called an illegal delegation of legislative authority. This is why I-code referenced standards always come with a date/edition (see the referenced standard chapter). The I-codes don’t reference any old edition of a standard, they reference a specific edition of that standard.

The other problem with simply saying ‘prevailing federal minimum efficiency’ is that it doesn’t tell the designer or the code official where to find those values. The solution is to cite the specific Federal law and date, just as is done with any standard referenced in the I-codes. Yes – this does lock in the efficiency standard used for 3 years. But that is what we do for every other standard.

Equipment efficiency is a key part of home energy efficiency. More efficient equipment saves more energy. Significant energy savings is available for every type of equipment efficiency. A high-efficiency 95 AFUE furnace saves energy. A high-efficiency 19 SEER air conditioner saves energy. Ground source heat pumps save considerable energy. Solar water heating saves energy. Homes that use more efficient equipment should get credit for choosing more efficient equipment. Equipment efficiency was a part of the residential IECC performance calculation in 2006 and prior. Equipment efficiency is part of the commercial IECC performance calculation, ASHRAE 90.1 and 90.2, to name a few.

Some argue that longer-life measures should not be traded for shorter-life measures. For example, don’t trade lower wall insulation for higher equipment efficiency. However the ERI allows one to trade higher-efficiency refrigerators, higher-efficiency clothes washers and higher-efficiency dishwashers for lower wall insulation. Clothes washers in particular are often moved with the owner when a house is sold. The lifetime of windows is less than insulation, should we allow better windows to be traded for lower wall insulation? I’d argue to keep all tradeoffs. However, if one argues to keep equipment efficiency tradeoffs out of Section R405 performance trades, then to be consistent one should also argue to keep equipment efficiency, refrigerators, clothes washers and dishwashers out of the tradeoffs for insulation in the ERI.

Why was equipment efficiency taken out of after the 2006 residential IECC? In the proponent’s opinion one reason was to protect the market for some types of products that thought equipment efficiency might compete and reduce their market share. For instance, some might use high
efficiency equipment instead of higher levels of insulation. The goal of the code should be to deliver energy efficiency, not to protect products.

Moving to even higher levels of energy efficiency in the code will require restoring flexibility, part of which is equipment efficiency. If builders get credit for what they do, be it equipment efficiency, solar, or whatever, then this proponent is comfortable asking them to achieve higher levels of efficiency, even increasing requirements through code. However, without flexibility, then builders need more exceptions and lesser requirements to make up for the flexibility they are denied by code. Without restoring flexibility, additional energy efficiency in code is much more difficult to achieve.

**Cost Impact:** The code change proposal will decrease the cost of construction
Allowing credit for high efficiency equipment will encourage energy efficiency and promote lower cost ways to get to energy efficient homes.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, 10 CFR 430.32 (2021), with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.
f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[
AF = A_s \times FA \times F
\]

where:

- \( AF \) = Total glazing area.
- \( A_s \) = Standard reference design total glazing area.
- \( FA = \frac{\text{(Above-grade thermal boundary gross wall area)}}{\text{(above-grade boundary wall area} + 0.5 \times \text{below-grade boundary wall area)}} \)
- \( F = \frac{\text{(above-grade thermal boundary wall area)}}{\text{(above-grade thermal boundary wall area} + \text{common wall area})} \) or 0.56, whichever is greater.

and where:

- Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.
- Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.
- Below-grade boundary wall is any thermal boundary wall in soil contact.
- Common wall area is the area of walls shared with an adjoining dwelling unit.

\( L \) and \( CFA \) are in the same units.

Reason: In 2012, the IRC and IECC were modified introducing "Whole House Mechanical Ventilation" which was required in one and two family dwelling units and townhouse construction, when tested to less than 5 ACH 50. This is essentially all such buildings as described. ASHRAE 62.2:2004 was used as a basis for the rate of ventilation, which designated the ventilation rate of whole house ventilation at \( Q_{\text{fan}} = 0.01A_{\text{floor}} + 7.5 \) (BR + 1). This version, is as according to the the 2012 IRC Code and Commentary. The more recent versions of ASHRAE 62.2-(2013 / 2016.) have recognized the need to improve indoor air quality, have revised the rate of ventilation to Mechanical Ventilation \( Q_{\text{fan}} = 0.03A_{\text{floor}} + 7.5 \) (BR + 1). This was done because the prior rate assumed a significant amount of outdoor air from infiltration, which due to improvements in the IECC, has steadily dropped, necessitating an increase in the mechanical ventilation rate. It is therefore not appropriate in 2019 to still be referencing ventilation rates from those outdated standards This revised rate = 0.03A floor + 7.5 (BR + 1) is also contained in ANSI/RESNET ICC-2014 which sets R406.3 Energy rating index at odds with itself, since there was a modification to the IECC code text of this section setting the ventilation rate back to \( Q_{\text{fan}} = 0.01A_{\text{floor}} + 7.5 \) (BR + 1). This issue will likely be the focus of a code change proposal by the authors of the RESNET standard.

Bibliography: 2018 IECC

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposal modifies the rate of mechanical ventilation to be consistent with ANSI/RESNET/ICC-2014 which utilizes ASHRAE 62.2-2013 for it's ventilation standard. This modification does not impose a cost to the code.

<tr>
<td></td>
<td>&gt;=90</td>
<td>2.8 cfm/watt</td>
<td>Any</td>
</tr>
</tbody>
</table>

For SI: 1 cfm = 28.3 L/min.

a. When tested in accordance with HVI Standard 916.

**Reason:** Changes to Table R405.5.2(1):

Ventilation system type is often selected as a function of climate, with supply systems seeing greater specification in the warm climates and exhaust systems seeing greater specification in cold climates. In keeping with ANSI/RESNET 301, this proposed change would compare the performance of the proposed design's ventilation system type with a comparable code-minimum ventilation system type for the reference home. The advantage of this change is that it permits builders and designers to select climate appropriate ventilation systems without receiving an automatic energy penalty that could be associated with the system type. As currently written, a builder selecting a heating or energy recovery ventilator (H/ERV) that meets the code minimum fan efficacy of 1.2 cfm/W would be penalized for not meeting the code minimum exhaust fan efficacy of 2.8-3.5 cfm/W, as determined by Table R403.6.1.

If approved, following are examples of how the reference home would be modeled based on the selection of the proposed design:

1. If the proposed design specifies an H/ERV, the reference home would be modeled with a balanced system without heat or energy recovery and having a fan efficacy of 1.2 cfm/W.
2. If the proposed design specifies a central fan integrated (CFI) system, the reference home would be modeled with an in-line supply fan with an efficacy of 3.8 cfm/W.

3. If the proposed design specifies a bathroom exhaust fan with a flow rate $\geq 90$ cfm, the reference home would be modeled with an exhaust fan with an efficacy of 2.8 cfm/W.

Changes to Table R403.6.1:

Changes proposed to this table are for clarification and simplification. First, the table should not be based on the location of the fan but on the type of fan being installed. For example, an HRV or ERV is not a location, but a system type. Balanced fans without heat recovery are currently omitted from the table, and should be listed along side HRVs and ERVs, which are also balanced systems. Because balanced fans are grouped with HRVs and ERVs, the use of the term "in-line fan" should be clarified to include supply and exhaust in-line systems (also not a location, but a system type). Finally, if a "bathroom" fan is installed in a hallway to provide ventilation (a typical installation location for whole-house mechanical ventilation systems), the current table is silent on the minimum efficacy required, because it does not address "hallway" fans. So, this proposal combines typical bathroom, utility room, and hallway exhaust fans into the category of "other exhaust fans": no changes are made to the fan efficacies for these products. The last column can be deleted by changing the "Air Flow Rate Minimum" column heading to "Air Flow Rate".

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Ultimately, ventilation system selection is up to the builder, so there is no increase or decrease in the cost of construction associated with this code change proposal.
## TABLE R405.5.2(1) [IRC N1105.5.2(1)]

### SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

Portions of table not shown remain unchanged.

</tbody>
</table>

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L,

\[\theta = \frac{\theta_F - 32}{1.8}, \quad 1 \text{ degree} = 0.79 \text{ rad}\]

**d.** For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

For a proposed design without a proposed heating system, an air-source heat pump heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

**e.** For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

**f.** For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type electric resistance water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

**Reason:** A single technology-blind baseline performance requirement is critical for a uniform and consistent implementation of the IECC performance path primary intent. Shifting to a single baseline design provides an equitable credit to all technologies that have lower annual costs compared to the single baseline level irrespective of energy form or technology design. It establishes fixed reference home performance requirements BEFORE making the technology and energy choices for the rated home. A single reference design methodology creates a level playing field for all technology and energy forms and provides equitable treatment of advanced renewable, waste heat recovery, hybrid, and multi-fuel technology options. It is especially important for equitable and consistent evaluation of on-site power generation and combined heat and power.
systems.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Options are already available in the current code. This change merely provides a more equitable baseline for performance comparisons.

**Staff Analysis:** Current table note d is deleted and the remaining table notes were relettered.
**RE180-19**

IECC: R405.3 (IRC N1105.3)

**Proponent:** Chris McTaggart, Building Efficiency Resources, representing Building Efficiency Resources (cmctaggart@theber.com)

## 2018 International Energy Conservation Code

**Revise as follows:**

**R405.3 (IRC N1105.3) Performance-based compliance.** Compliance based on simulated energy performance requires that a proposed residence (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the standard reference design. Energy prices shall be taken from a source approved by the code official, such as the Department of Energy, Energy Information Administration’s State Energy Data System Prices and Expenditures reports. Code officials shall be permitted to require time-of-use pricing in energy cost calculations.

**Exception:** The energy use based on source energy expressed in Btu or Btu per square foot of conditioned floor area shall be permitted to be substituted for the energy cost that is less than or equal to the annual source energy use of the standard reference design. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

**Reason:** The current R405 option to demonstrate compliance using comparative annual energy cost between the proposed design and standard reference design introduces an inappropriate additional variable of utility costs that can radically confuse compliance. The ratios between fuel and electricity costs are constantly changing, which can result in a proposed design based on a builder’s typical set of architectural plans that achieves compliance on the day that the costs were aggregated, but which does not comply days or months after when costs change. Therefore you can have two homes built from the same planset, with the same specs, built to the same code by the same builder in the same geographic area with one being compliant and the other non-compliant, simply because of variations in the ratios of electric vs fuel costs over time. Similarly, you could have two homes built from the same planset, with the same specs, built to the same code by the same builder at the exact same time in the same geographic area - but in different energy utility territories - with one being compliant and the other non-compliant, simply because they use different utility providers with differing costs.

Furthermore, it is an excessive burden for a code official to have to create and implement their own process for validating the energy utility cost data used in the software file. For one, there is little guidance in the code for code officials for how to define what cost data or process of creating/maintaining cost data is acceptable. The current code suggests that EIA state-average data could be used, which is ok, but should this data be updated monthly? Annually? The EIA state-average data fluctuates month-by-month, and is often seasonal in nature; some software programs allow seasonal inputs, but again - is that what's expected or is it simply an annual average? How often should this cost data be updated? What if a barely-passing planset in a residential development no longer passes with updated energy cost data after the first year of a multi-year build out? If not using EIA data, finding actual data from the specific utilities in question is a huge undertaking, as the fee, rate and tariff sheets from utilities are typically massive and complex.

There are simply too many questions, variables and outliers associated with cost-based compliance due to the variability and ever changing nature of energy costs. This introduces confusion and a "wildcard" that the code official may not truly understand or understand how to reasonably assess what's fair and reasonable. The “x-factor” of energy costs and the relative difference between fuels and electricity introduce an independent variable that really has to use when assessing building energy efficiency from a compliance standpoint. It is not reasonable to have a variable such as cost be able to change the same planset's compliance within the same code cycle depending on what and when cost data is pulled, and potentially utility vs utility.

This proposal seeks to simplify the Performance compliance process by focusing on known, fixed energy use calculations, resulting in a compliance path that is based exclusively on building energy characteristics and climate data. The proposal maintains the previous "exceptions" of using source energy use or use per sqft of conditioned floor area (otherwise known as a source EUI). While there no doubt has been fair debate over time regarding site vs source energy, electricity vs fuel source energy factors, total energy vs EUI, etc, this proposal does not seek to resolve those conflicts but instead elects to adopt the previous "exception" compliance options already adopted into previous energy codes.

To document the need for this change, I have uploaded two PDF compliance documents produced from REM/Rate software for a planset seeking to comply with the current 2012 IECC with state amendments in Iowa. The proposed design complies with the code by achieving exact cost compliance in dollars as the standard reference design when using 2015 EIA state average cost data, which were the current costs at the time this planset was originally run in the software for compliance. When updating the model to only change costs to the most up-to-date EIA state data (2017), the home now does not comply with the code as the proposed design is estimated to cost more to operate than the standard reference design.

Currently, all software programs that are popularly used to demonstrate compliance (REM/Rate, REM/Design, Ekotrope, EnergyGauge) are set up to create R405 compliance reports exclusively compute cost compliance; they are not set up to express compliance using annual source energy. However, all of these software programs have the ability to configure the Performance compliance reports for either annual source energy or EUI.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
This proposal will have no impact on construction costs. There will be a minor cost to software providers to alter the Performance compliance calculations to annual source energy or source EUI vs cost, but they will unlikely pass these costs down to their users. This proposal will save time and money for code officials and AHJs by reducing the need for the code official to have to police energy cost data in Performance code software.

Proposal # 5478
Proponent: Terry Kozlowski, representing Southern Nevada Chapter; Amanda Moss, representing SN-ICC Member; Cassidy Wilson, representing SN-ICC Member; Valarie Evans, representing Southern Nevada Chapter

2018 International Energy Conservation Code

Revise as follows:

R406.2 (IRC N1106.2) Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code. R406.2. The mandatory thermal envelope requirements referenced in this section and Section R406.4 may be met by utilizing the Total UA Alternative referenced in Section R402.1.5.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

R-values are minimums, U-factors and SHGC are maximums. R-19 batts compressed into a nominal 2 x 6 framing cavity such that the R-value is reduced by R-1 or more shall be marked with the compressed batt R-value in addition to the full thickness R-value.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

c. "15/19" means R-15 continuous insulated sheathing on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. "15/19" shall be permitted to be met with R-13 cavity insulation on the interior of the basement wall plus R-6 continuous insulated sheathing on the interior or exterior of the home. "10/13" means R-10 continuous insulated sheathing on the interior or exterior of the home or R-13 cavity insulation at the interior of the basement wall.

d. R-5 shall be added to the required slab-edge R-values for heated slabs. Insulation depth shall be the depth of the footing or 2 feet, whichever is less in Zones 1 through 3 for heated slabs.

e. There are no SHGC requirements for the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

g. Or insulation sufficient to fill the framing cavity. R-19 minimum.
Reason: The UA Alternative in Section R402.1.5 meets the intent and energy performance of code, using UA value tradeoffs within the envelope to deliver maximum efficiency in delivering envelope performance. The UA Alternative should be available to residential builders regardless of whether the builder is using prescriptive, performance or ERI approach because it encourages innovation and response to individual market/climate factors without minimizing envelope performance. Furthermore, adoption of this approach in the base IECC will encourage adoption of base code, instead of individual jurisdictions lessening prescriptive requirements of R406.4 to achieve the flexibility needed.

Using an approved energy simulation tool, a builder can trade-off elements of the building thermal envelope to achieve superior energy performance, while having the same overall UA value.

A requirement to refer to a previous code cycle for information requires multiple code books with multiple cycles which causes confusion. By adding the information from the table in the 2009 IECC to the 2021 IECC, this allows the use of a single document.

Bibliography: R101.5.1 Compliance materials. The code official shall be permitted to approve specific computer software, worksheets, compliance manuals and other similar materials that meet the intent of this code.

ENERGY SIMULATION TOOL. An approved software program or calculation-based methodology that projects the annual energy use of a building.

Cost Impact: The code change proposal will decrease the cost of construction. This allows builders to adjust envelope features based on climate zone and orientation of a structure. The optimal delivery of envelope efficiencies in that location and orientation could result in savings.

Proposal #4346

RE181-19
2018 International Energy Conservation Code

Revise as follows:

**R406.2 (IRC N1106.2) Mandatory requirements.** Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2018 International Energy Conservation Code.

**Exception:** Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

<table>

<td>58</td>
</tr>
<tr>
<td>8</td>
<td>58</td>
</tr>
</tbody>
</table>

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

**Reason:** The purpose of this code change proposal is to make two important updates to the Energy Rating Index. First, this proposal makes an editorial improvement by moving footnote “a” of Table R406.4 into Section R406.2, which contains the other mandatory requirements for the ERI. Given that two different thermal envelope backstops apply to the ERI depending on whether on-site renewable energy is included in the calculation, it makes sense to put these two backstops side-by-side in the same section of the code to reduce or eliminate any confusion.

Second, this proposal will update the enhanced thermal envelope backstop for homes with on-site renewable energy from the 2015 to the 2018 IECC, maintaining the same approach as set in the 2018 IECC – specifically, using the prescriptive path from the previous code as a backstop in this situation. This backstop is crucial to use of the ERI with on-site renewable energy. We continue to be concerned about the potential magnitude of trade-off credit that may apply if on-site generation is included in the ERI calculation. Analyses have shown that homes can achieve a 20-40 HERS points reduction with average-sized solar PV systems, which would allow enormous trade-offs of the home’s permanent envelope efficiency. See, e.g., RESNET, The Impact of Photovoltaic Arrays on the HERS Index (2015); and https://www.energycodes.gov/sites/default/files/documents/ECodes2016_06_Haack.pdf. Without reasonable limits on these solar trade-offs, homes with on-site generation could be built with far less efficiency, including substandard thermal envelopes, creating long-term problems for homeowners and reversing many of the benefits created by the IECC over the past 10 years.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The editorial change to move the footnote into Section R406.2 will have no cost impact, and because the 2018 IECC incorporated only very moderate increases in efficiency over the 2015 IECC (primarily window improvements with no real upgrade cost), we expect no real cost impact. Moreover, this enhanced backstop only applies to homes built to the ERI that incorporate on-site power production into the ERI calculation, which is currently a very small percentage of all code-compliant homes. Code users can also avoid any cost increase by using other compliance approaches.
alternatives.

Proposal # 4009

RE182-19
2018 International Energy Conservation Code

Revise as follows:

R406.3 (IRC N1106.3) Energy Rating Index. The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-1:

\[
\text{Ventilation rate, CFM} = \left( 0.01 \times \text{total square foot area of house} \right) + \left[ 7.5 \times \left( \text{number of bedrooms} + 1 \right) \right]
\]

(Equation 4-1)

Energy used to recharge or refuel a vehicle used for transportation on roads that are not on the building site shall not be included in the ERI reference design or the rated design.

Reason: The language being proposed for deletion was approved during the 2018 IECC development cycle. Here is the proponent’s reason statement from the proposal:

“As written the ERI ventilation rate specification is in conflict with the ventilation rate specified by the IRC. The current language references ANSI/RESNET/ICC Standard 301 which references the ASHRAE 62.2-2013. The ventilation rate in the ASHRAE Standard 62.2 is significantly higher than the ventilation rate in the IRC. The IRC rate was reaffirmed in Group A changes this code cycle. Without this ventilation rate correction, the higher ventilation rate would use more energy unnecessarily and thereby increase ERI scores for no good reason. Interestingly the ASHRAE 62.2-2010 used the same rate as is in the current IRC.

Third party organizations should not set ventilation rates for the IRC and the IECC. Ventilation rates in the IRC and IECC should be set by the ICC code development process. This proposal brings the IECC/IRC ERI calculation into compliance with the IRC ventilation rate by using the same ventilation equation as will be in Section 1507.3.3 of the 2018 IRC. The published committee reason expected this update, stating: “The difference in ventilation rate might need to be resolved but the experts can solve that through public comments.” This is the public comment they were referring to.”

The proponent makes this statement: “Without this ventilation rate correction, the higher ventilation rate would use more energy unnecessarily and thereby increase ERI scores for no good reason.” In a study conducted by the Florida Solar Energy Center (FSEC), it was found that this change, as included in the 2018 IECC, actually increases ERI scores from 2-10 points, depending on climate zone. The reason for this is that the rated home under Standard 301 is not allowed to use a ventilation rate less than ASHRAE 62.2-2013. Since the 2018 IECC changed the reference home to require less ventilation than the rated home, the home will be shown to use more energy and increase the ERI score.

In a second statement the proponent says: “Third party organizations should not set ventilation rates for the IRC and IECC.” This statement is also false. ANSI/RESNET/ICC Standard 301 does not require any specific ventilation rate, nor does RESNET take a position as to proper ventilation rates. RESNET’s Standard Development Committee 300 chose to reference the most recent ANSI-approved standard for ventilation rates which is ASHRAE 62.2:2013. The standard does not require homes to meet those ventilation rates, instead, the standard simply doesn’t give any “credit” (in the form of lower index scores) for ventilation rates that are less than required by ASHRAE 62.2.

When the proponent of this change in the 2018 cycle, submitted a proposal to change Standard 301, SDC 300 rejected the change with the following reason statement:

“ASHRAE Standard 62.2 is the sole American National Standard on ventilation for indoor air quality in low-rise residential buildings. RESNET has chosen to not conflict with this indoor air quality standard. ANSI/RESNET/ICC Standard 301 does not require any specific level of outdoor air ventilation. However, in order not to encourage outdoor air ventilation levels that do not meet the indoor air quality requirements of ASHRAE Standard 62.2, RESNET has chosen to provide no Energy Rating Index credit for ventilation air flow rates that are less than those required by ASHRAE Standard 62.2. There is no other American National Standard on ventilation for indoor air quality and RESNET has chosen to not provide credits for outdoor air ventilation rates that do not achieve this level of indoor air quality. ANSI/RESNET/ICC Standard 301 does not "require" any level of outdoor air ventilation. Rather it simply stops giving outdoor air exchange energy reduction credit at the 62.2 ventilation specification. The commenter would better seek resolution of the issue raised by this comment by working with the ASHRAE to amend ASHRAE Standard 62.2.”

This change did not achieve the proponent’s stated objectives during the 2018 code development cycle. By NOT approving this change to delete the ventilation requirement for the reference home, the committee would be allowing Section R406 to be out of alignment with Standard 301.

RESNET acknowledges that the scientific and political discussions regarding the “correct” ventilation rate for residential homes is contentious. Neither RESNET nor Standard 301 seek to determine the correct ventilation rate for homes.
At the time ANSI/RESNET/ICC 301-2014 was published, the published American National Standard for Ventilation and Acceptable Indoor Air Quality in Low-Rise Residential Buildings was ASHRAE 62.2-2013. To align with published American National Standards for indoor air quality, RESNET chose to adopt the ventilation rates prescribed by ASHRAE 62.2-2013. RESNET considers this decision to be procedural. RESNET as an organization acknowledges ventilation is important for homes that are built to modern building energy code standards, which require fairly tight envelopes. However, RESNET is neutral regarding the “correct” ventilation rate. To facilitate this neutrality, RESNET Standards do not penalize homes with ventilation rates that are less than ASHRAE 62.2-2013 Standard minimum ventilation rates but RESNET also does not provide energy credit for such homes.

Regardless of which rate may be best, the ERI calculation procedure does not establish requirements for home ventilation rates. Rather such requirements are established by building code authorities and model codes such as set forth in Section R403.6 of the 2018 IECC. The ventilation rates used in the ANSI/RESNET/ICC 301 procedure do not change or modify any requirements of building codes or standards.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This code change proposal does not impact construction practices in any way and, therefore, does not increase the cost of construction. The proposal only impacts how the home is modeled within the energy modeling software, but does not require a home to meet any specific ventilation rate.

Proposal # 4857
**RE184-19**

IECC: R406.3 (IRC N1106.3)

**Proponent:** William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

**2018 International Energy Conservation Code**

Revise as follows:

**R406.3 (IRC N1106.3) Energy Rating Index.** The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-1.

\[ \text{Energy used to recharge or refuel a vehicle used for transportation on roads that are not on the building site shall not be included in the ERI reference design or the rated design.} \]

For compliance purposes, any reduction in energy use of the rated design associated with on-site renewable energy shall not exceed 5 percent of the total energy use.

**Reason:** The purpose of this code change proposal is to help ensure that homes are built to an appropriate level of efficiency, irrespective of the amount of on-site generation that may be installed. The proposal adopts a 5 percent cap on the trade-off credit allowed for on-site power in the Energy Rating Index, similar to the 5 percent cap that applies in the simulated performance analysis of the 2018 IECC commercial chapter, Section C407.3, and ASHRAE Standard 90.1-2016 Energy Cost Budget Method.

- **2018 IECC C407.3:** “…The reduction in energy cost of the proposed design associated with on-site renewable energy shall be not more than 5 percent of the total energy cost.”
- **ASHRAE Standard 90.1-2016, Section 11.4.3.1:** “…The reduction in design energy cost associated with on-site renewable energy shall be no more than 5% of the calculated energy cost budget.”

It is important to note that this proposal does not limit the amount of on-site power production that can be installed on the home, nor does it apply any sort of “penalty” to homes with on-site power. The proposal simply recognizes that a reduction in energy use is not the same thing as on-site energy production, for purposes of code compliance. This proposal also supports the long-term goal of achieving net zero energy use by helping avoid steps backward in efficiency as on-site generation increases. If unlimited efficiency trade-off credit is allowed for increases in on-site generation, progress toward net-zero energy will stall. We do not see any good reason to allow steps backward in efficiency when it can be improved simultaneously with increases in on-site power production.

**Cost Impact:** The code change proposal will increase the cost of construction

The code change proposal will increase the cost of construction only if user selects the ERI compliance path and the cost of increased on-site power production is less than a commensurate amount of energy efficiency. However, given the long expected useful life of a home's permanent features (such as thermal envelope efficiency), we believe homeowners will experience lower costs and reduced risk over the long-term if trade-off credit for on-site power production is reasonably limited.

Proposal # 4013
**RE185-19**

IECC: R406.4 (IRC N1106.4) (New)

**Proponent:** Craig Conner, representing self (craig.conner@mac.com)

**2018 International Energy Conservation Code**

Add new text as follows:

**R406.4 (IRC N1106.4) Energy cost** The ERI as specified by Section 4.1 of RESNET 301 shall be computed with the energy cost as specified by Section R405.3.

**Reason:** The ERI path energy cost calculation should be consistent with the energy cost calculation in the performance path (Section R405). RESNET created their own method, the "normalized Modified End Use Load". The "normalized Modified End Use Load" is a complicated calculation that is inconsistent with the IECC's performance calculation in R405. The RESNET calculation is shown below in the bibliography. The ERI cost calculation should be consistent with the cost calculation in the IECC's performance calculation (Section R405).

**Bibliography:** Here is the normalized Modified End Use Load from RESNET 301

ANSI/RESNET/ICC 301-2019 page 17-18

4.1.1. Calculating End Use Loads. The normalized Modified End Use Loads (nMEUL) for space heating and cooling and service hot water use shall each be determined in accordance with Equation 4.1-1:

\[
\text{nMEUL} = \text{REUL} \times (\text{nEC}_x / \text{EC}_r) \quad \text{(Eq. 4.1-1)}
\]

where:
- \(\text{nMEUL}\) = normalized Modified End Use Loads (for heating, cooling, or hot water) as computed using an Approved Software Rating Tool.
- \(\text{REUL}\) = Reference Home End Use Loads (for heating, cooling or hot water) as computed using an Approved Software Rating Tool.
- \(\text{nEC}_x\) = normalized Energy Consumption for the Rated Home’s end uses (for heating, including Auxiliary Electric Consumption, cooling or hot water) as computed using an Approved Software Rating Tool.
- \(\text{EC}_r\) = estimated Energy Consumption for the Reference Home’s end uses (for heating, including Auxiliary Electric Consumption, cooling or hot water) as computed using an Approved Software Rating Tool.

and where:

\[
\text{nEC}_x = (a \times \text{EEC}_x - b) \times (\text{EC}_x \times \text{EC}_r \times \text{DSE}_r) / (\text{EEC}_x \times \text{REUL}) \quad \text{(Eq. 4.1-1a)}
\]

where:
- \(\text{EC}_x\) = estimated Energy Consumption for the Rated Home’s end uses (for heating, including Auxiliary Electric Consumption, cooling or hot water) as computed using an Approved Software Rating Tool.
- \(\text{EEC}_x\) = Equipment Efficiency Coefficient for the Rated Home’s equipment, such that \(\text{EEC}_x\) equals the energy consumption per unit load in like units as the load, and as derived from the Manufacturer’s Equipment Performance Rating (MEPR) such that \(\text{EEC}_x\) equals 1.0 / MEPR for AFUE, COP or EF ratings, or such that \(\text{EEC}_x\) equals 3.413 / MEPR for HSPF, EER or SEER ratings.
- \(\text{DSE}_r\) = \(\text{REUL} / \text{EC}_r \times \text{EEC}_r\)

For simplified system performance methods, \(\text{DSE}_r\) equals 0.80 for heating and cooling systems and 1.00 for hot water systems [see Table 4.2.2(1)]. However, for detailed modeling of heating and cooling systems, \(\text{DSE}_r\) less than 0.80 occurs as a result of part load performance degradation, coil air flow degradation, improper system charge and auxiliary resistance heating for Heat Pumps. Except as otherwise provided by these Standards, where detailed systems modeling is employed, it must be applied equally to both the Reference and the Rated Homes.

- \(\text{EEC}_r\) = Equipment Efficiency Coefficient for the Reference Home’s equipment, such that \(\text{EEC}_r\) equals the energy consumption per unit load in like units as the load, and as derived from the Manufacturer’s Equipment Performance Rating (MEPR)
such that $\text{EEC}_r$ equals $1.0 / \text{MEPR}$ for AFUE, COP or EF ratings, or such that $\text{EEC}_r$ equals $3.413 / \text{MEPR}$ for HSPF, EER or SEER ratings and where the coefficients ‘a’ and ‘b’ are as defined by Table 4.1.1(1) below:

4.1.2. Calculating the Energy Rating Index. The Energy Rating Index shall be determined in accordance with Equation 4.1-2:

$$\text{Energy Rating Index} = \text{PEfrac} \times (\text{TnML} / (\text{TRL} \times \text{IAF}_{RH})) \times 100 \quad \text{ (Eq. 4.1-2)}$$

where:

- $\text{TnML} = n\text{MEUL}_{HEAT} + n\text{MEUL}_{COOL} + n\text{MEUL}_{HW} + \text{EUL}_{LA} \text{ (MBtu/y)}$.
- $\text{TRL} = \text{REUL}_{HEAT} + \text{REUL}_{COOL} + \text{REUL}_{HW} + \text{REUL}_{LA} \text{ (MBtu/y)}$.
- $\text{IAF}_{RH} = \text{Index Adjustment Factor of Rated Home, per Eq. 4.3-2}$

and where:

- $\text{EUL}_{LA} = \text{The Rated Home end use loads for lighting, appliances and MELs as defined by Section 4.2.2.5.2, converted to MBtu/y, where MBtu/y = (kWh/y)/293 or (Therms/y)/10, as appropriate.}$
- $\text{REUL}_{LA} = \text{The Reference Home end use loads for lighting, appliances and MELs as defined by Section 4.2.2.5.1, converted to MBtu/y, where MBtu/y = (kWh/y)/293 or (Therms/y)/10, as appropriate.}$

and where:

- $\text{PEfrac} = (\text{TEU} - \text{OPP}) / \text{TEU}$
- $\text{TEU} = \text{Total energy use of the Rated Home including all rated and non-rated energy features where all fossil fuel site energy uses (Btu_{fossil}) are converted to equivalent electric energy use (kWh_{eq}) in accordance with Equation 4.1-3.}$
- $\text{OPP} = \text{On-Site Power Production as defined by Section 4.2.2.6 of this Standard.}$

$$\text{kWh}_{eq} = (\text{Btu}_{fossil} \times 0.40) / 3412 \quad \text{ (Eq. 4.1-3)}$$

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The choice of calculation does not inherently increase or decrease costs. However calculations based on energy cost will better align with the energy costs the consumer sees.
RE186-19
IECC: R406.3 (IRC N1106.3)

Proponent: Craig Conner, representing self (craig.conner@mac.com); Joseph Lstiburek, representing self (joe@buildingscience.com)

2018 International Energy Conservation Code
Revise as follows:

R406.3 (IRC N1106.3) Energy Rating Index. The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-1:

\[
\text{Ventilation rate, CFM} = (0.01 \times \text{total square foot area of house}) + [7.5 \times (\text{number of bedrooms} + 1)]
\]

(Exception 4-1)

Exceptions:

1. For Table 4.2.2(1) of RESNET/ICC 301, the Reference Home and Rated Home air exchange rates shall be as specified for the air exchange rates in Table R405.5.2(1) of this code.
2. For Table 4.3.1(1) of RESNET/ICC 301, the air exchange rate shall be as specified for the air exchange rate for the standard reference design in Table R405.5.2(1) of this code.
3. The proposed ventilation rate shall comply with the mechanical ventilation requirements of Section M1505 of the International Residential Code or Section 403.3.3.2.1 of the International Mechanical Code. Energy used to recharge or refuel a vehicle used for transportation on roads that are not on the building site shall not be included in the ERI reference design or the rated design.

Reason: RESNET/ICC 301 uses the ASHRAE 62.2 ventilation rate not the IRC and IMC ventilation rate. Following the ASHRAE 62.2 ventilation rate results in over ventilation in hot humid climates and cold climates and excessive energy use in all climates. In hot humid climates the resulting part load humidity problems result in mold. In cold climates the high ventilation rates result in excessive dryness. Beyond the problems created by over ventilation, this is also a policy issue. Ventilation rates are set in the I-code development process, not by RESNET. The ERI is being used to show compliance with the I-codes. The IRC and the IMC set building code ventilation rates not RESNET. The ERI should be determined using building code ventilation rates specified by the IRC and the IMC not by RESNET.

RESNET/ICC 301 by following ASHRAE 62.2 also modifies the mechanical ventilation rate required based on infiltration measurements and this results in discouraging better building practices. Tighter houses are penalized compared to leakier houses which makes no sense. If a builder constructs a leakier house then the mechanical ventilation rate is reduced according to RESNET/ICC 301 and ASHRAE 62.2. Infiltration should not be relied on to provide ventilation in new code compliant house construction where enclosures are constructed to 3 ach@50 Pa and 5 ach@50 Pa. Finally, ventilating at a higher, and unnecessary, ventilation rate wastes energy.

If RESNET has an issue with the IRC and the IMC ventilation rates then RESNET should change the ventilation rates using the ICC code change process and not force the use of the ASHRAE 62.2 ventilation rates to judge I-code compliance.

The existing wording has proved confusing. The proposed wording is much clearer. This code change requires that the IRC and IMC ventilation rates be used to determine the ERI.

Cost Impact: The code change proposal will decrease the cost of construction
For those who believe they have to use ASHRAE 62.2 ventilation rates this reduce costs. Even if done "right" over ventilation increases costs due to the costs of dealing with excessive moisture, overly dry air, or moisture damage in some climates.
IECC: R406.3 (IRC N1106.3)

Proponent: Amanda Hickman, The Hickman Group, representing The Leading Builders of America (LBA) (amanda@thehickmangroup.com)

2018 International Energy Conservation Code

Revise as follows:

R406.3 (IRC N1106.3) Energy Rating Index. The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-1.

\[
\text{Ventilation rate, CFM} = (0.01 \times \text{total square foot area of house}) + (7.5 \times (\text{number of bedrooms} + 1))
\]

(Exception 4-1)

Exceptions:

1. The infiltration and ventilation rate calculated in accordance with ANSI/RESNET/ICC 301 section 4.3.3.2.5 shall be permitted to be less than the rate allowed in ANSI/RESNET/ICC 301, provided the actual whole-house ventilation rate complies with the mechanical ventilation requirements of the International Residential Code Section M1505 or the International Mechanical Code Section 403.3.2.1.

2. For the purposes of calculating the ERI of the rated home, the greater of either the minimum allowable Air exchange rate specified by ANSI/RESNET/ICC 301 Table 4.2.2 (1) or the proposed ventilation rate of the Rated Home shall be used for The Air exchange rate in ANSI/RESNET/ICC 301 Table 4.2.2 (1).

Reason: This proposal corrects language that was introduced to this section last cycle that was intended to address the over-ventilation issue that was occurring. However, what was intended to fix this problem, ended up creating another one. Separating the ventilation rates out from the ANSI/RESNET/ICC 301 standard, created two sets of ERI scores (one in ICC and one in RESNET). This is causing huge confusion in the market and with enforcement.

This proposal introduces two exceptions that will simplify and clarify the language while resolving both issues. It corrects the over-ventilation problem while eliminating the double ERI scores. Exception 1 is for the HERS raters, while Exception 2 is for the software programmers.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal only clarifies how to apply actual ventilation rate in the proposed design.

Proposal # 5335
2018 International Energy Conservation Code
Revise as follows:

TABLE R406.4 (IRC N1106.4)
MAXIMUM ENERGY RATING INDEX

<table>
<thead>
<tr>
<th>CLIMATE ZONE</th>
<th>ENERGY RATING INDEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>61</td>
</tr>
<tr>
<td>7</td>
<td>58</td>
</tr>
<tr>
<td>8</td>
<td>58</td>
</tr>
</tbody>
</table>

Section R402.1.5, "Total UA alternative", allows a UA tradeoff of one component U-factor provided it was made up by another component. Likewise the performance calculation in R405 would allow a component R-value below the R-value in the table, provided the overall building energy use met code. There is no such restriction on tradeoffs in RESNET 301. Why can’t the “flexible” ERI in the IECC do the same?

There are multiple other reasons to delete the footnote. It is poor form to put significant requirements in a footnote, even more so for unneeded requirements. Is the SHGC even covered by the footnote? The footnote says to meet SHGC requirements in one of two tables, but Table 402.1.4 does not even have an SHGC requirement. Finally naming another year’s IECC makes the code harder to use. Section R406 names both the 2009 and 2015 IECC. Is the code user supposed to keep the 2009, 2015 and the upcoming 2021 IECC in order to use Section 406? The footnote is unnecessary and should be deleted.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This removes a limitation on flexibility. If anything it will reduce costs.
**RE189-19**

IECC: R406.3 (IRC N1106.3)

**Proponent:** Ted Williams, representing American Gas Association (twilliams@aga.org)

**2018 International Energy Conservation Code**

Revise as follows:

**R406.3 (IRC N1106.3) Energy Rating Index.** The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-1.

\[
\text{Ventilation rate, CFM} = (0.01 \times \text{total square foot area of house}) + [7.5 \times (\text{number of bedrooms} + 1)]
\]

(Equation 4-1)

Energy used to recharge or refuel a vehicle used for transportation on roads that are not on the building site shall not be included in the ERI reference design or the rated design.

**Reason:** This language is redundant with other rating requirements and is not necessary. The Energy Rating Index (ERI) is determined in accordance with RESNET/ICC 301 Standard, which does not include vehicle charging/refueling in the end use loads and the Home Energy Rating System (HERS) Index.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction Since the proposed deletion addresses redundancy in requirements, it would neither increase nor decrease construction costs.

Proposal # 5593
IECC: R406.4 (IRC N1106.4), TABLE R406.4 (IRC N1106.4)

Proponent: Joseph H. Cain, Solar Energy Industries Association (SEIA), representing Solar Energy Industries Association (SEIA) (JoeCainPE@gmail.com)

2018 International Energy Conservation Code

Revise as follows:

R406.4 (IRC N1106.4) ERI-based compliance. Compliance based on an ERI analysis requires that the rated design including renewable energy systems be shown to have an ERI less than or equal to the appropriate value indicated in Table R406.4 when compared to the ERI reference design.

</tbody>
</table>

TABLE R406.4 (IRC N1106.4)
Maximum Energy Rating Index

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

Reason: The Energy Rating Index is a voluntary path that ensures robust insulation and envelope measures while enabling on-site renewables that enhance the affordability of a home in select climate zones.

In the process of development of the 2018 IECC, in the Public Comment version of RE173-16 the ERI target scores were increased (relaxed) and Footnote a was added to treat projects differently if they do or do not incorporate an on-site renewable energy system. Projects that include a renewable energy system to offset consumption of energy and reduce energy flows at the meter are not rewarded in this revised approach, but are penalized by requiring a higher level of envelope measures. Footnote a requires IECC 2015 envelope backstop for projects with on-site renewable energy systems or 2009 envelope backstop for projects without on-site renewable energy systems. The result is an ERI compliance option that focuses on the building envelope with less-stringent target scores that can be attained without renewable energy systems -- a disincentive for builders to use renewable energy systems in the ERI path.

As presented by the Building Technologies Office of the Department of Energy’s 2018 National Energy Codes Conference, according to the U.S. Energy Information Administration's AEO 2018 report, typical Residential End Uses include Space heating at 24% and Space cooling at 11%, for a combined space heating/cooling at 35% of all Residential Energy End Uses. Water heating accounts for 13.5% of Residential Energy End Uses. These figures illustrate that we have done a very good job of reducing regulated loads, such that unregulated loads (such as lighting loads, appliance loads, and plug loads) now represent greater than 50% of all Residential Energy End Uses. Renewable energy systems can offset not only the unregulated loads, but can also offset the reduced regulated loads.

Compliance measures and compliance paths that focus only on building envelope measures and discourage or penalize renewable energy systems - or fail to make renewable energy systems attractive to builders as a compliance option -- are focused on solving 35% of the problem. The IECC should encourage the use of energy efficiency plus renewable energy, to solve 100% of the problem. In fact, new homes with PV systems and EV chargers can also power our consumer vehicles with sunlight, solving greater than 100% of the building energy problem.

This proposal restores the lower, more stringent ERI target values of the 2015 IECC and again makes renewable energy systems an attractive option for builders.

Effective integration of energy efficiency measures and renewable energy systems is critical to the future of energy codes and green/stretch/reach codes. At the time of submittal of these code change proposals, there are four states with 100% renewable energy goals: Hawaii, California, New Jersey, and New York. Other communities are committing to renewable energy goals through their own local renewable goals for power supply or
for installation of renewable energy systems. Distributed Generation (DG) is an important component of these overall portfolio standards.

**Bibliography:** U.S. Energy Information Administration Annual Energy Outlook 2018
https://www.eia.gov/outlooks/aeo/index.php

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal encourages the installation of renewable energy systems, which provides more flexibility to the builder and could result in either increased or decreased first cost of construction, depending on builder choices.
Proponent: Lauren Urbanek, representing Natural Resources Defense Council (lurbanek@nrdc.org)

2018 International Energy Conservation Code
Revise as follows:

TABLE R406.4 (IRC N1106.4)
MAXIMUM ENERGY RATING INDEX

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

Reason: The purpose of this proposal is to increase the efficiency of homes built to the Energy Rating Index, to reflect average HERS scores already being achieved in each climate zone. Data from RESNET shows that in 2017, the average HERS score being achieved in each climate zone is, in many cases, already lower than the requirements in the 2018 IECC. Homes are already being built to the proposed values in each of the climate zones, so the numbers proposed are inherently realistic. Therefore, it is appropriate to adjust the ERI scores to better reflect reality.

Furthermore, as building component technology and the efficiency of systems and equipment continues to improve, it is important to continue to promote ever-increasing levels of efficiency in the IECC. When the ERI targets were first set during the 2015 code cycle, the RESNET HERS system, could not calculate energy savings from certain hot water energy efficiency measures. The RESNET HERS system has since been modified to account for energy savings from certain hot water efficiency measures. These savings are based on simple and inexpensive measures such as lower-flow plumbing fittings and hot water layouts that minimize water waste.

The subsequent increase in HERS scores in the 2018 IECC made this path of the code less stringent – and in fact, builders in most climate zones already exceed the 2018 requirements. The values in this proposal are more stringent than the 2018 IECC, yet still not as stringent as the 2015 requirements.

By strengthening the ERI scores in Table R406.4, the IECC will drive further innovation, better building practices, and more energy cost savings for homeowners.

Cost Impact: The code change proposal will increase the cost of construction

This code change proposal requires more efficiency in the ERI path of the code, which means that the cost of construction may increase for builders following this path of code as compared to if they were meeting the minimum requirements of the 2018 ERI path. However, the ERI scores in this proposal are based off of the average values reported to RESNET in 2017 for homes being built in each climate zone. That means that builders are already building to these values – regardless of what values are in the code – and so the cost of construction will not go up in many cases. Furthermore, this proposal only affects the ERI compliance path, which is only one compliance option and will not increase the cost of construction available to the builder under other compliance options.
2018 International Energy Conservation Code

Revised as follows:

TABLE R406.4 (IRC N1106.4)
MAXIMUM ENERGY RATING INDEX

<table>

<td>54</td>
</tr>
</tbody>
</table>

**a.** Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

**Reason:** The purpose of this code change proposal is to establish lower, more efficient ERI target scores, improving efficiency for homes complying under the Energy Rating Index. More precisely, the proposal restores the lower ERI Index target scores from the 2015 IECC. Under the ERI, the lower the score, the more efficient the home. Although the ERI numbers were increased to the current levels as part of a broad compromise in the 2018 IECC, we believe that over time the ERI must continue to be improved, and improving the Index numbers by returning to the 2015 IECC levels at some point is a reasonable first step in the right direction.

Although a direct comparison between the ERI and other IECC compliance options is complicated, the ERI numbers proposed (and those in the 2015 IECC) are within the range of equivalence to other compliance paths under the IECC. U.S. DOE published an analysis that compared compliance under the IECC with HERS scores, using over 60,000 model runs to test the range of HERS scores that could apply to a 2012 IECC-compliant home. The study found that the 2015 ERI scores would be more likely to ensure compliance with the IECC, but even those scores could not guarantee compliance. “Thus, one can conclude that the [2015 IECC] ERIs are generally very near the conservative end of possible values, but not quite so low as to always guarantee that a home complying via the ERI path would also comply via the Performance Path.” See U.S. Department of Energy, *Identification of RESNET HERS Index Values Corresponding to Minimal Compliance with the IECC Performance Path*, at 4.17 (May 2014). Given that the other compliance options in the IECC have moderately improved since the 2012 IECC, we believe that these more stringent ERI scores would be appropriate as an upgrade to the current less efficient ERI levels for 2021.

**Bibliography:** See U.S. Department of Energy, *Identification of RESNET HERS Index Values Corresponding to Minimal Compliance with the IECC Performance Path*, at 4.17 (May 2014).

**Cost Impact:** The code change proposal will increase the cost of construction.

To achieve a lower ERI score, builders must install more efficient products or systems in homes, which will increase construction costs. Because the ERI is a performance-based path, the costs and benefits to the consumer will vary depending on which improvements are incorporated into the home design. However, since the ERI is not mandatory and is one of only several compliance options, builders are not required to use this option if they do not find it acceptable for a specific project.

RE193-19
IECC: R406.2 (IRC N1106.2), ICC Chapter 6 (IRC Chapter 44)

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Gutman, BCAP-IBTS, representing BCAP-IBTS (mgutman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code
Revise as follows:

R406.2 (IRC N1106.2) Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” and Section R403.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficients in Table 402.1.1 or 402.1.3 of the 2009 2012 International Energy Conservation Code.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an R-value of not less than R-6.

Reason: The purpose of this code change proposal is to help ensure that homes built to the Energy Rating Index (ERI) incorporate a reasonably efficient thermal envelope by updating the minimum thermal envelope backstop from the prescriptive level in the 2009 IECC to the 2012 edition of the IECC. We view this improvement as part of a broader effort to gradually improve the efficiency of the IECC and to reduce the likelihood that homes will be built with below-average levels of efficiency in the thermal envelope. A robust thermal envelope is crucial to long-term energy conservation. The ERI gives builders an unprecedented amount of flexibility in achieving code compliance. Unlike other compliance methods, using the ERI compliance path, builders may take credit for efficiency improvements in HVAC equipment, appliances, and lighting. To help reduce the risk of a home being built with an exceptionally weak permanent thermal envelope, Section R406.2 currently requires an ERI-rated home to meet or exceed the prescriptive thermal envelope requirements of the 2009 IECC. We believe this requirement is very easily achieved by the vast majority of homebuilders (some of whom are building beyond the code’s base requirements), but it is an important consumer protection all the same. State and local policymakers agree—our knowledge, in every state in which the ERI has been adopted as part of a 2015 or 2018 IECC update, the 2009 thermal envelope backstop has also been adopted.

The ERI thermal envelope backstop is now due for an update. By the time the 2021 IECC is finalized, the 2009 IECC will be 12 years old (and given the typical lag of state code adoption, the lag could be even longer).

The modification proposed above strikes a balance between efficiency and flexibility, while updating one of the IECC’s most important built-in backstops. The building’s permanent thermal envelope will outlast many of the shorter-term improvements (such as HVAC equipment, lighting, and appliances).

Cost Impact: The code change proposal will increase the cost of construction. However, the prescriptive requirements (including those for the thermal envelope) of the 2012 IECC have been found cost-effective by US DOE. See U.S. Department of Energy, National Energy and Cost Savings for New Single- and Multifamily Homes: A Comparison of the 2006, 2009, and 2012 editions of the IECC (April 2012) available at https://www.energycodes.gov/sites/default/files/documents/NationalResidentialCostEffectiveness.pdf. We believe that those who currently use the ERI will be able to comply with 2012 IECC thermal envelope requirements with little or no additional effort. However, for those builders that would have traded away more of the thermal envelope efficiency, the proposal above will apply a reasonable limit to these trade-offs.

Proposal # 4008
Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

b. In a state, region, or country that has a renewable portfolio standard of 50% or greater, on-site renewable electric energy production systems shall receive credit only where they are installed with an on-site energy storage system that has a rated capacity of at least 3.5 kWh.

SECTION R202 (IRC N1101.6)
GENERAL DEFINITIONS

Add new definition as follows:

RENEWABLE PORTFOLIO STANDARD (RPS). A policy that requires electricity producers within a given jurisdiction to supply a certain minimum amount, capacity, or percentage of their electricity from designated renewable resources.

Reason: More states / areas of the United States are increasing their Renewable Portfolio Standards. As more distributed renewable electric energy systems are installed, there are situations where there is too much supply and too little demand, especially in the fall, winter, and spring. In California, this has been called the “duck curve”. In Hawaii, this has been called the “Nessie curve”. In these cases, the grids are dealing with the issue of oversupply. In 2018, the California ISO had to curtail over 461,000 MWh (461 Million kWh) of solar and wind electric generation.

Energy storage, both grid-side and customer-side, will be needed to help address this situation. With energy storage, there is much less likelihood (or even no chance) that renewable electricity will be curtailed or not used.

In the newest version of Title 24, builders are allowed to adjust the size of residential PV systems if they also installed energy storage systems in combination with the PV.

This proposal is forward looking and will help both homeowners and the grid in the future, especially in areas with aggressive Renewable Portfolio Standards.

The definition is needed for support of the new language in the proposal. This is an “umbrella” definition that encompasses all of the variations of RPS policies throughout the United States (and world). RPS policies vary on a state by state basis, as there is no federal standard in the United States. However, in other countries that use the IECC, there may be country-wide policies that would be in effect.

More details about RPS policies can be found on numerous web sites, including the following:
https://www.eia.gov/todayinenergy/detail.php?id=4850 (US DOE/EIA article from 2012)

http://programs.dsireusa.org/system/program?type=38&

**Cost Impact:** The code change proposal will increase the cost of construction
Based on current battery technology and costs, the estimated cost impact will be approximately $1750 (3.5 kWh * $500/kWh installed) for homes that are located in areas with high RPS requirements and that install on-site renewable electric energy generation systems.
RE195-19
IECC: TABLE R406.4 (IRC N1106.4)

Proponent: Steven Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

2018 International Energy Conservation Code
Revise as follows:

<table>
<thead>
<tr>
<th>CLIMATE ZONE</th>
<th>ENERGY RATING INDEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>57</td>

</tbody>
</table>

a. Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

b. Where the installation of an on-site renewable energy system is a mandatory requirement in the code, the building shall receive credit only for the capacity installed that is above the minimum mandatory requirement.

Reason: In California, the latest version of Title 24 will go into effect on 1/1/2020. In the energy code, there is a requirement for new homes to install on-site PV systems, based on the following formula:

\[
\text{kW PV} = \frac{(\text{CFA} \times A)}{1000} + (\text{NDwell} \times B)
\]

Where:

- kW PV = kWdc size of the PV system
- CFA = Conditioned floor area
- NDwell = Number of dwelling units
- A = Adjustment factor from Table 150.1-C (range of 0.572 to 1.56)
- B = Dwelling adjustment factor from Table 150.1-C (range of 1.06 to 1.51)

There are exceptions to the requirement, but most homes will be required to install systems that range in size from 2 to 5 kW.

Under the ERI compliance path, homes with such systems get credits (lower scores). However, if such systems are already required by the code, should they receive full credit?

With other efficiency programs, once the federal or state baseline is increased (e.g., 10 to 13 SEER, for example), the incentives for the 13 SEER system disappear, since it is no longer a "high efficiency" option, but a required minimum standard.

This proposal follows that precedent. Systems that meet the mandated minimum requirements should not receive credit, since they are not going "above and beyond" what is required. Only systems that exceed the minimum requirements should get credit for the incremental energy production they are providing.

Bibliography:
- California Energy Commission, "2019 Standards Part 6 Chapter 8 (Section 150.1) Revised Express Terms" TN-223257-3

Cost Impact: The code change proposal will increase the cost of construction

Where the PV system is sized larger than the required minimum, the extra cost will be on the order of $2,700 per kW (DC) of incremental peak rated capacity. The value is based on the November 2018 NREL report on US solar installations at residential facilities.
For example, if the minimum requirement is 3 kW (DC), and a 5 kW (DC) system is installed, the extra cost will be approximately $5,400.
2018 International Energy Conservation Code

Revise as follows:

### TABLE R406.4 (IRC N1106.4)
MAXIMUM ENERGY RATING INDEX

<table>

</tbody>
</table>

Where on-site renewable energy is included for compliance using the ERI analysis of Section R406.4, the building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to within 15% of the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4 of the 2015 International Energy Conservation Code.

**Reason:** This modification gives on-site renewable energy a 15% credit of the current edition of the code when using the Energy Rating Index. It clears up confusion about calling reference to past editions of the IECC and enables the code user to use one edition of the code instead of referencing a past edition. As the code is written right now there is no credit for installing on-site renewable energy while mandating rigorous prescriptive requirement of the 2015 IECC with no room for flexibility. The prescriptive tables have been virtually untouched in the 2018 edition and could potentially go unchanged for cycles to come. The ERI path is intended to allow for flexibility while constructing an energy efficient home. The proposal gives a reasonable amount of flexibility without jeopardizing the integrity or efficiency of the homes. The 15% allowance will prevent from installing single pane windows and prevent significant reductions in building thermal envelope components.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal does not change the cost of construction it increases the flexibility.
RE197-19
IECC: R406.5 (IRC N1106.5)

Proponent: Ryan Meres, RESNET, representing RESNET (ryan.meres@gmail.com)

2018 International Energy Conservation Code
Revise as follows:

R406.5 (IRC N1106.5) Verification by approved agency. Verification of compliance with Section R406 shall be completed by an approved third party, working under the auspices of an approved rating provider as defined in ANSI/RESNET/ICC 301.

Reason: In the 2018 IECC, Standard 301 is only referenced for the calculation of the ERI. However, there are many other aspects of Standard 301 that address implementation items, like: inspection of minimum rated features, certified raters, approved rating providers and labeling. Without any reference to some of these items in the code, there are no requirements other than an “approved” third party to verify compliance. Unfortunately, that provides little guidance to the local code official. In addition, there is currently no quality assurance requirements under the ERI path. Homes complying with the ERI path will only be subject to quality assurance if they are using the HERS index and submit a “Confirmed” rating to RESNET. In Standard 301 an “Approved Rating Provider” is defined as: An approved entity responsible for the certification of home energy raters working under its auspices and who is responsible for the quality assurance of such Certified Raters and for the quality assurance of home energy ratings produced by such home energy raters.

In Standard 301 a “Certified Rater” is defined as: An individual who has become qualified to conduct home energy ratings through certification by an Approved Rating Provider.

In Standard 301 “Approved” is defined as: shall mean approved by an entity adopting and requiring the use of this Standard as a result of investigation and tests conducted by the entity or by reason of accepted principles or tests by nationally recognized organizations.

After having the ERI path in the code for two cycles now, it has become clear that there is confusion about the nuances of its implementation in the field. This change will help to clarify any confusion about who should be approved as a third party to verify compliance with the ERI path.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The Home Energy Rating System (HERS) Index is the most common option for ERI compliance. All RESNET Certified HERS Raters are required to work under the auspices of a Quality Assurance Provider. Therefore, this proposal is simply recognizing an industry practice that already exists and will not lead to any increase to the cost of construction.
2018 International Energy Conservation Code

Revised as follows:

R406.5 (IRC N1106.5) Verification by approved agency. Verification of compliance with Section R406 shall be completed by an approved third-party that has been accredited to ISO/IEC 17065.

Reason: The ERI path has been a welcome addition of the IECC. The DOE Home Energy Rating Variability Study [https://www.energycodes.gov/sites/default/files/documents/NECC2018_11_Williams.pdf] showed unacceptably high levels of variance in ERI ratings however, which begs the question of if ERI is an acceptable and defendable means of consistently demonstrating CODE Compliance. I think the answer is that it CAN be oversight of the ERI is strengthened beyond what currently exists. Using an consensus body developed Standard, in the same vein as RESNET/ICC 380, NFRC 400 and HVI Standard 916, is a reasonable means of accomplishing this. Specifically using the ANSI-developed Standard (ISO/IEC 17065) that the EPA is already moving to include in to its ENERGY STAR for Homes program for the verifying the ERI of dwellings in the program is only logical choice.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The code change proposal will not increase or decrease the cost of construction but it will increase the quality of service and results expected of 3rd-party verifiers.

Proposal # 4045
RE199-19
IECC: R406.5 (IRC N1106.5)

Proponent: Robby Schwarz, EnergyLogic, representing EnergyLogic (robbys@nrglogic.com)

2018 International Energy Conservation Code
Revise as follows:

R406.5 (IRC N1106.5) Verification by approved agency. Verification of compliance with the Section R406 as outlined in Section R406.4 and R406.6 shall be completed by an approved third party. Verification of Section R406.2 shall be completed by the authority having jurisdiction or an approved third party inspection agency per Section R105.4.

Reason: R406.5 Verification by an approved agency. Currently, this section is causing confusion between jurisdictions and approved third parties. Many jurisdictions believe that the third party is verifying all aspects of the energy code while many approved third parties believe they should only generate the ERI score. This is leading to homes that are not getting fully code verified because fundamentally the development of an ERI score solely, and ERI Rating, is different from a full code compliance rating.

The HERS Index benchmarks the efficiency of a home in comparison to a reference home that is based on the 2006 IECC. A HERS Rating is an asset rating of the energy features in a home. This means that in the process of a HERS Rating to generate the HERS Index a Rater does not necessarily inspect to see if energy features governed by the code are installed according to requirements of the code. For example, the HERS Ratings systems’ insulation installation grading criteria gives guidance on how to de-rate the R-value of poorly installed insulation. The Rater is required to give a grade 3 to poor installations. The HERS Index score is intended to evaluate the performance of what is installed. It is not intended to determine if it was installed per the requirement of code. A code rating or evaluation for the generation of the ERI score, on the other hand, should only use a grade 1 because only grade 1 installation of insulation meets the requirements of manufacturer instructions and therefore code. If a Rater were to evaluate a home for an ERI score and come across grade 3 installation of insulation, the installation should fail the inspection and be re-installed to meet code requirements.

In this way, an ERI rating and a HERS rating are fundamentally different. One is held to a pass/fail requirement of code and the other is a quantification and evaluation of energy assets or components of the home. This small example demonstrates how the HERS index score and the ERI score differ.

The language that is added to this section clearly defines that the generation of the ERI score is in the approved third parties’ scope of work and that the remainder of the code compliance verification be performed by the third party or not, depending on the agreement between the jurisdiction and the third party.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This code change proposal does not increase the cost of construction or the utilization of this pathway in the code. It merely defines how to use the path to ensure compliance with the code.
RE200-19

IECC: R406.5.1 (IRC N1106.5.1) (New)

Proponent: Ryan Meres, representing RESNET (ryan.meres@gmail.com)

2018 International Energy Conservation Code

Add new text as follows:

R406.5.1 (IRC N1106.5.1) Quality Assurance Approved third party verifiers and all residential buildings demonstrating compliance with Section R406 shall comply with the quality assurance requirements in accordance with ANSI/RESNET/ICC 301.

Reason: There has been confusion about the differences between ERI and HERS, especially when it comes to quality assurance requirements. Currently, under the 2018 IECC, a permit applicant could submit an ERI Compliance Report to demonstrate compliance with the energy code without any requirement subjecting that rating to quality assurance. The only way a home complying with the ERI path will be subject to quality assurance is if that home uses a HERS rating and a “confirmed” rating is submitted to RESNET. Sections 5.1.4.1.3 and 5.1.4.2.3 of ANSI/RESNET/ICC 301 require that “Confirmed” and “Sampled” ratings be subject to Quality Assurance requirements “equivalent to Section 900 of the Mortgage Industry National Home Energy Rating Systems Standard.”

One of the most important benefits of the ERI compliance path is the requirement for third party verification of compliance. Many local code officials are under the misconception that all homes using the ERI for compliance are subject to quality assurance. Unfortunately, this is not true.

This proposal would require that the approved third party verifiers are working under a program that has quality assurance requirements; and the homes they’re responsible for verifying are subject to those quality assurance standards.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The Home Energy Rating System (HERS) Index is the most common option for ERI compliance. All RESNET Certified HERS Raters are required to work under the auspices of a Quality Assurance Provider. Therefore, this proposal is simply recognizing an industry practice that already exists and will not lead to any increase to the cost of construction.

Proposal # 4911
RE201-19
IECC: R406.5.2 (IRC N1106.5.2) (New)

**Proponent:** Ryan Meres, RESNET, representing RESNET (ryan.meres@gmail.com)

### 2018 International Energy Conservation Code

Add new text as follows:

**R406.5.2 (IRC N1106.5.2) Compliance documentation for certificate of occupancy.** Third parties that have been approved to verify compliance with R406 shall provide the following documentation to the code official, prior to issuance of a certificate of occupancy:

1. Documentation that the approved third party is certified by an approved rating provider in accordance with ANSI/RESNET/ICC 301;
2. Documentation demonstrating that the mandatory requirements in R406.2 have been met;
3. A compliance report in accordance with R406.6.2 that is clearly indicated as a “Confirmed Rating” or “Sampled Rating” as defined by ANSI/RESNET/ICC 301;
4. Documentation of air leakage testing results in accordance with R402.4.1.2;
5. Documentation of duct leakage testing results in accordance with R403.3.3.

**Reason:** Despite education efforts, there is confusion among code officials and third party verifiers about the documentation that should be required, prior to the issuance of a certificate of occupancy, for compliance with the ERI path. Since this is still a relatively new compliance path for the IECC, the proponents of this proposal feel that it is necessary to provide guidance to local code officials and third party verifiers. This proposal seeks to add each of the proposed documentation items for the following reasons:

1. This provision ensures that third party verifiers are subject to quality assurance procedures
2. This item ensures that third party verifiers are verifying the mandatory requirements of the IECC and not just what’s required to conduct the rating
3. ANSI/RESNET/ICC 301 only requires “Confirmed” and “Sampled” ratings to be subject to quality assurance, so this item ensures that third parties are not submitting a “projected” rating to the code officials that is not subject to quality assurance
4. Documenting the envelope air leakage results ensures that those numbers are in alignment with the figures used in obtaining the ERI score
5. Documenting the duct leakage results ensures that those numbers are in alignment with the figures used in obtaining the ERI score

Overall, this proposal will improve consistency among third parties and code officials in documenting compliance with the ERI path.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal does not add any construction requirements to the code. It simply requires that some basic documentation be submitted to demonstrate compliance with R406.

Proposal # 4912
2018 International Energy Conservation Code

Revise as follows:

R406.6.2 (IRC N1106.6.2) Compliance report. Compliance software tools shall generate a report that documents that the ERI of the rated design complies with Sections R406.3 and R406.4. The compliance documentation shall include the following information:

1. Address or other identification of the residential building.
2. Declare Energy Rating Index on title page.
3. An inspection checklist documenting the building component characteristics of the rated design. The inspection checklist shall show results for both the ERI reference design and the rated design, and shall document all inputs entered by the user necessary to reproduce the results.
4. Name of individual completing the compliance report.
5. Name and version of the compliance software tool.

Exception: Where an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements in each of the four (north, east, south and west) cardinal orientations.

Reason: This code change is being proposed to clarify the energy path to the code official and the documentation for permit. Many reports do not specify the path that is being proposed and the code official has to contact the applicant to verify the energy path they are intending to use, to comply with the energy code. By providing the method of compliance the code official can focus on the details of the report and this information will expedite the permit process time.

Cost Impact: The code change proposal will increase the cost of construction
This will increase the cost of construction by a minor amount, adding a data entry to the report.
RE203-19
IECC: R406.6.2 (IRC N1106.6.2)

Proponent: William Fay, Energy-Efficient Codes Coalition, representing Energy-Efficient Codes Coalition (bfay@ase.org); Daniel Bresette, Alliance to Save Energy, representing Alliance to Save Energy (dbresette@ase.org); Maureen Guttman, BCAP-IBTS, representing BCAP-IBTS (mguttman@bcapcodes.org); Harry Misuriello, American Council for an Energy-Efficient Economy, representing American Council for an Energy-Efficient Economy (misuriello@verizon.net)

2018 International Energy Conservation Code

Revise as follows:

R406.6.2 (IRC N1106.6.2) Compliance report. Compliance software tools shall generate a report that documents that the ERI of the rated design complies with Sections R406.3 and R406.2 through R406.4. The compliance documentation shall include the following information:

1. Address or other identification of the residential building.
2. An inspection checklist documenting the building component characteristics of the rated design. The inspection checklist shall show results for both the ERI reference design and the rated design, and shall document all inputs entered by the user necessary to reproduce the results. The checklist shall document compliance with each requirement under Section R406.2.
3. Name of individual completing the compliance report.
4. Name and version of the compliance software tool.

Exception: Where an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements in each of the four (north, east, south and west) cardinal orientations.

Reason: The purpose of this proposal is to correct what we believe to be an omission in the Energy Rating Index compliance report and to provide additional clarity and direction to software makers about how to incorporate the mandatory backstop provisions of the ERI into compliance software. The compliance report outlined in Section R406.6.2 does not currently require software to document whether the project complies with the mandatory provisions of Section R406.2. The proposal above corrects this by adding Section R406.2 to the list of sections to be included in the compliance report and adds the requirements of Section R406.2 to the inspection checklist. Although mandatory provisions and backstops have been a part of the IECC for many years, software designed for voluntary or “above-code” programs (such as HERS rating software) may not directly address mandatory items or treat them with the appropriate level of importance. Code officials understand very well that when a provision is listed as “mandatory,” the building simply cannot achieve compliance without meeting that provision. Now that more and more code users are turning to software and rating professionals for code compliance, it is important to provide additional details for software developers as to how to incorporate these important provisions.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

No code requirements are changed by this proposal, but the addition of the mandatory requirements to the compliance report and checklist will help ensure quality construction and facilitate code compliance.

Proposal # 4011

RE203-19
RENEWABLE ENERGY CERTIFICATE (REC). An instrument that represents the environmental attributes of one megawatt hour of renewable energy; also known as an energy attribute certificate (EAC).

Add new text as follows:

R406.6.3 (IRC N1106.6.3) Renewable energy certificates (RECs) documentation. Where onsite renewable energy is included in the calculation of an ERI, one of the following forms of documentation shall be provided to the code official:

1. Substantiation that the RECs associated with the onsite renewable energy are owned by, or retired on behalf of, the homeowner.
2. A contract that conveys to the homeowner the RECs associated with the onsite renewable energy, or conveys to the homeowner an equivalent quantity of RECs associated with other renewable energy.

Reason: This proposal impacts who may claim the environmental attributes of an onsite-renewable energy system. The environmental attributes of solar power, or other renewable energy, have market value that is reflected and transacted in RECs. When the installer, leasing company or financial agent in the solar panel transaction strips that value from the homeowner by taking possession of the RECs, according to the Federal Trade Commission the power produced by the solar panels on the house would have an "unqualified claim" as renewable energy. To prevent this, the proposal ensures that environmental attributes are not double counted towards compliance with the IECC. While this proposal does not cite Green-E, the Green-E Standard describes the double counting that occurs when RECs have been transferred to another party in the renewable transaction:

Examples of prohibited double uses include, but are not limited to:

1) When the same REC is sold by one party to more than one party, or any case where another party has a conflicting contract for the RECs or the renewable electricity;

2) When the same REC is claimed by more than one party, including any expressed or implied environmental claims made pursuant to electricity coming from a renewable energy resource, environmental labeling or disclosure requirements. This includes representing the energy from which RECs are derived as renewable in calculating another entity’s product or portfolio resource mix for the purposes of marketing or disclosure;

3) When the same REC is used by an electricity provider or utility to meet an environmental mandate, such as an RPS, and is also used to satisfy customer sales under Green-e Energy; or

4) Use of one or more attributes of the renewable energy or REC by another party. This includes when a REC is simultaneously sold to represent "renewable electricity" to one party, and one or more attributes associated with the same MWh of generation (such as CO2 reduction) are also sold, to another party.

To prevent the situation where double counting is credited within the ERI calculation, thereby artificially reducing ERI scores and allowing the homeowner to install fewer energy efficiency features than otherwise would be required, this proposal ensures that the homeowner retains possession of the RECs associated with onsite renewable energy systems. In the case where those RECs for the onsite system cannot be transferred to the homeowner, an equivalent quantity of RECs must be provided.

Bibliography: Federal Register, Volume 77, Number 197; October 11, 2012; 16 CFR Part 260; "Guides for the Use of Environmental Marketing Plans".

Cost Impact: The code change proposal will increase the cost of construction

This proposal impacts who may claim the environmental attributes of an onsite-renewable energy system. The environmental attributes of the solar power have market value, reflected in RECs. The cost of installing solar panels may be reduced when the installer, leasing company or financial agent strips that value from the homeowner by taking possession of the RECs.
2018 International Energy Conservation Code

Revised as follows:

R406.4 (IRC N1106.4) ERI-based compliance. Compliance based on an ERI analysis requires that the rated proposed design and confirmed built dwelling be shown to have an ERI less than or equal to the appropriate value indicated in Table R406.4 when compared to the ERI reference design.

R406.6.2 (IRC N1106.6.2) Compliance report. Compliance software tools shall generate a report that documents that the home and the ERI score of the rated design complies with Sections R406.2, R406.3 and Section R406.4. The compliance documentation shall be created for the proposed design and shall be submitted with the application for the building permit. Confirmed compliance documents of the built dwelling unit shall be created and submitted to the code official for review before a certificate of occupancy is issued. Compliance reports shall include information in accordance with Sections R406.6.2.1 and R406.6.2.2, include the following information:

1. Building street address or other building site identification.
2. The name of the individual performing the analysis and generating the compliance report.
3. The name and version of the compliance software tool.
4. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. A certificate indicating that the proposed design has an ERI less than or equal to the appropriate score indicated in Table R406.4 when compared to the ERI reference design. The certificate shall document the building component energy specifications that are included in the calculation including, component level insulation R-values or U-factors, assumed duct system and building envelope air leakage testing results, as well as the type and rated efficiencies of proposed heating, cooling, mechanical ventilation, and service water heating equipment to be installed. If onsite renewable energy systems will be installed the certificate shall report the type and production size of the proposed system.
6. When a site-specific report is not generated, the proposed design shall be based on the worst-case orientation and configuration of the rated home.

Add new text as follows:

R406.6.2.1 (IRC N1106.6.2.1) Proposed compliance report for permit application. Compliance reports submitted with the application for a building permit shall include the following:
1. Building street address or other building site identification.
2. The name of the individual performing the analysis and generating the compliance report.
3. The name and version of the compliance software tool.
4. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.

R406.6.2.2 (IRC N1106.6.2.2) Confirmed compliance report for a certificate of occupancy. A confirmed compliance report submitted for obtaining the certificate of occupancy shall be made site and address specific and include the following:
1. Building street address or other building site identification.
2. The name of the individual performing the analysis and generating the report.
3. The name and version of the compliance software tool.
4. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. A final confirmed certificate indicating that the confirmed rated design of the built home complies with Sections R406.2 and R406.4. The certificate shall report the energy features that were confirmed to be in the home including component level insulation R-values or U-factors, results from any required duct system and building envelope air leakage testing, as well as, the type and rated efficiencies of the heating, cooling, mechanical ventilation, and service water heating equipment installed. When onsite renewable energy systems have been installed on or in the home the certificate shall report the type and production size of the installed system.

Reason: The word Rating defines a process by which one can systematically and repeatably assess and inspect a home. One can perform a code rating, an energy rating, a program or EnergyStar rating, and so on. In this way the process of evaluation may differ in that an Energy Rating is an asset rating while a Code Rating is a compliance rating. So, although the evaluation can be different Ratings ensure that verification of installed features is the same.
Section R405 Simulated Performance Alternative and Section R406 Energy Rating Index Compliance Alternative both use a rating process for verifying compliance of the home, so the bulk of this code change proposal adds language to this section that is the same as used in Section R405 to explain what is needed to demonstrate compliance for obtaining the building permit (proposed design) and what is needed in order to release the certificate of occupancy (confirmed Reports).

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This code change proposal does not increase the cost of construction or the utilization of this pathway in the code. It merely defines how to use the path to ensure compliance with the code.
# 2018 International Energy Conservation Code

Revised as follows:

**R401.2 (IRC N1101.13) Compliance.** Projects shall comply with Section R401.2.1 and one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Add new text as follows:

**R401.2.1 (IRC N1101.13.1) Additional Energy Efficiency (Mandatory).** This section establishes additional requirements applicable to all compliance approaches to achieve additional energy efficiency.

1. For buildings complying under Sections R401 through R404, one or more additional energy efficiency measures shall be installed in accordance with Section R407.2 that cumulatively equal or exceed 5 Flex Points.
2. For buildings complying under the simulated performance alternative in Section R405, the building shall meet one of the following:
   2.1. One or more additional energy efficiency measures in Section R407.2 shall be installed that cumulatively equal or exceed five Flex Points, without including such measures in the proposed design under Section R405; or
   2.2. The proposed design of the building under Section R405.3 shall have an annual energy cost that is less than or equal to 95 percent of the annual energy cost of the standard reference design.
   2.3. For buildings that comply under the energy rating index alternative in Section R406, the energy rating index value shall be at least 5 percent less than the energy rating index target specified in Table R406.4.

## R407 (IRC N1107)

### FLEX POINTS FOR ADDITIONAL ENERGY EFFICIENCY

**R407.1 (IRC N1107.1) Scope.** This section establishes flex point alternatives to achieve additional energy efficiency in accordance with Section R401.2.

**R407.2 (IRC N1107.2) Flex Points for additional energy efficiency.** Measures shall be selected from Table R407.2. Each measure chosen shall receive credit for the Flex Points as indicated in the Table for the specific Climate Zone. Interpolation of points between measures shall not be permitted.

a. Climate Zone 4C is Climate Zone Marine 4.

b. The Total UA shall be calculated in accordance with Section R402.1.5 Total UA alternative.

c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be ≥ 75% Sensible Recovery Efficiency (SRE), ≤ 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be ≥ 50% Latent Recovery/Moisture Transfer (LRMT).

d. As defined by Section R403.3.7.

e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table R407.2 and shall be sized to serve 100% of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.

f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table R407.2 and shall be sized to serve 100% of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.

Reason: The purpose of this code change proposal is to improve overall residential building efficiency (heating, cooling and water heating energy) by roughly 5% and to create a scalable, flexible means of improving residential building efficiency for future IECC updates. Instead of requiring efficiency improvements to specific building components, the new “Flex Points” approach in Section R407 provides a multitude of options for builders to achieve the efficiency requirements of the IECC. This approach is also scalable according to a jurisdiction’s needs – states or localities who need additional energy savings to meet energy or climate policy goals can adjust the number of required points accordingly. Package- or points-based approaches have been used for several years in Washington and Oregon. And since the 2012 IECC, the commercial provisions have included section C406 Additional Efficiency Package Options. We believe the updated approach in this proposal is a sensible means of achieving additional efficiency now and in the future.

This proposal is similar to the Flex Points proposal for the 2018 IECC in overall structure, but the points table has been simplified and updated based on feedback received in the previous Code Development Cycle. Like the previous version, this proposal also includes alternative compliance pathways for builders who select the simulated performance alternative or the Energy Rating Index, and will bring roughly equivalent improvements to all three compliance paths.

This Flex Points proposal is cost-effective, since it includes a number of options to achieve 5 points that are cost-effective.

The Flex Points proposal will provide three distinct benefits for jurisdictions adopting the 2021 IECC:

1. **This proposal meets a clear need for efficiency improvements in the model energy code now and in the future.**

Although the IECC has made small efficiency gains in the 2015 and 2018 editions, major gains have plateaued. Buildings still consume an estimated 42% of the nation’s energy, 54% of its natural gas, and 71% of its electricity. Governors, legislators, and mayors are increasingly turning to building energy codes to meet energy and climate goals, and those codes should continue to provide reasonable improvements going forward. The U.S. Conference of Mayors, in its fourth consecutive resolution on the subject, reiterated their “concerted support for putting future triennial IECC updates on a “glide path” of steady efficiency gains that will improve the efficiency performance of millions of U.S. residential, multi-family, and commercial
Several jurisdictions have already created or are in the process of creating package-based compliance paths or improved code provisions to meet their policy needs. The result is improved efficiency, but a lack of consistency in both format and requirements. Incorporating Flex Points into the 2021 IECC will not only provide a 5% boost in energy conservation but will also provide a realistic map for additional improvements going forward. And by providing more uniform targets for the efficiency of building components, this proposal will contribute to economies of scale, potentially lowering prices for builders and ultimately consumers.

2. This proposal will provide maximum flexibility for builders to achieve improved efficiency.

Flex Points trusts that builders and design professionals will select the most cost-effective and sensible efficiency improvements for a given project. There are several alternatives for compliance in each climate zone, along with options to comply in a performance- or rating-based path. There are alternatives related to more insulation, more efficient windows, reduced air and duct leakage and improved equipment. We believe that this approach provides the right incentives for builders to make long-lasting improvements in residential buildings that are in the best interests of homeowners.

The point values have been calculated based on the present value of energy cost savings over the current code (including relevant federal equipment efficiency standards) and reflect the estimated useful life of each measure over an assumed 30-year life of the building. While a 30-year period is consistent with the typical life of a mortgage, it is a very conservative period given the likelihood that some measures will provide efficiency benefits for decades beyond the initial 30-year period.

The analysis behind the Flex Points is based on the methodology and assumptions included in the U.S. Department of Energy’s Methodology for Evaluating Cost-Effectiveness of Residential Energy Code Changes, including the economic equations to obtain the present value of energy costs within the calculation methodology. The energy consumption calculations take into consideration heating, cooling, and water heating energy, using DOE-2 energy simulation across 105 TMY3 weather locations and 12 building types to account for varying stories, foundations, and fuel types for each of the baseline and upgrade measures. The analysis compares the annual energy savings between a home with and without an efficiency measure over the useful life of the efficiency measure using useful life data from NAHB and other sources. Energy costs were calculated using the most recent national EIA projections for natural gas and electricity. Because the analysis uses readily-available and widely-accepted tools and methodologies, we expect that future additions or changes will be straightforward.

3. This proposal will encourage efficiency improvements in building components that are currently difficult to regulate.

Flex Points addresses two issues that have complicated model energy codes for many years. First, innovative building practices or emerging technologies can benefit from being listed in codes, but states (and national code developing organizations) are reluctant to require new technologies or practices before they are market-tested. As a result, there are high barriers to entry for new technologies, even when they could transform the marketplace and provide energy- or cost-saving benefits for homeowners. As an example, Heat Recovery Ventilators (HRVs) are cost-effective and reasonable for much of the country, but individual circumstances or climate conditions may favor another approach. Rather than require HRVs in every case, or most cases with exceptions, HRVs and Energy Recovery Ventilators are included as one of several options available to builders in every climate zone. Not only will Flex Points create an opportunity for good technology to be used in more buildings, but it will open the door for market forces to make these technologies more widely available (and presumably less expensive to consumers). As new technologies or practices become available, these advances can be quickly and easily added into the Flex Points table, fast-tracking technology that is good for consumers.

Second, much of the heating, cooling, and water heating equipment installed in residential buildings is subject to federal preemption under the National Appliance Energy Conservation Act. As has been debated at length in ICC Code Development hearings over the last 15 years, including equipment efficiencies in performance trade-offs tends to weaken the efficiency of the energy code, since federal minimum efficiencies for nearly every covered product is well below the efficiency levels of commonly installed products. When these efficiency levels are used in trade-off baselines, builders use the improved efficiency of common heating, cooling, and water heating products as a means of trading away efficiency of more permanent building components and features, even though the equipment would have been installed anyway. This “free ridership” may provide short-term cost savings for homebuilders, but it saddles homeowners with unexpected high energy costs over the entire useful life of the building. Moreover, this equipment often carries a much shorter useful life, which is not typically captured in code compliance simulations.

Flex Points creates a new incentive to improve the efficiency of covered products without resulting in efficiency rollbacks elsewhere in the code. Heating, cooling, and water heating improvements (among others) are included among the Flex Points options with points calculated according to climate-specific energy cost savings and the longevity of the equipment. As compared to the previous Flex Points proposal, the list of options has been simplified and refocused on the equipment most likely to provide meaningful energy savings. Each of these upgrades will build upon the current IECC efficiency, rather than trading it away.

In sum, we believe that this proposal will improve efficiency by roughly 5% while unlocking the competitive market for new technologies or building components that are difficult to regulate and will provide a useful new tool for policymakers across the country – all without rolling back the effectiveness or efficiency of the IECC.

**Cost Impact:** The code change proposal will increase the cost of construction. Requiring additional efficiency measures, such as more insulation, more efficient windows, reduced air leakage and duct leakage, and/or more efficient equipment, to save 5% energy will increase the cost of construction, but the resulting energy and cost savings will recoup the initial costs and will continue to benefit consumers over the useful life of the home.

Proponent: Eric Makela, New Buildings Institute, representing Northwest Energy Codes Group (ericM@newbuildings.org)

2018 International Energy Conservation Code

Revise as follows:

R401.2 (IRC N1101.13) Compliance. Projects shall comply with Section R401.2.1 one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Add new text as follows:

R401.2.1 (IRC N1101.13.1) Additional Energy Efficiency (Mandatory) This section establishes additional requirements applicable to all compliance approaches to achieve additional energy efficiency.

1. For buildings complying under Sections R401 through R404, one or more additional energy efficiency measure(s) shall be installed in accordance with Section R407.2 that cumulatively equal or exceed 10 (ten) Flex Points.
2. For buildings complying under the simulated performance alternative in Section R405, the building shall meet one of the following: (a) one or more additional energy efficiency measure(s) in Section R407.2 shall be installed that cumulatively equal or exceed ten Flex Points, without including such measures in the proposed design under Section R405; or (b) the proposed design of the building under section R405.2 shall have an annual energy cost that is less than or equal to 90% of the annual energy cost of the standard reference design.
3. For buildings that comply under the energy rating index alternative in Section R406, the energy rating index value shall be at least 10% less than the energy rating index target specified in Table R406.4.

SECTION R407 (IRC N1107)
FLEX POINTS FOR ADDITIONAL ENERGY EFFICIENCY

R407.1 (IRC N1107.1) Scope. This section establishes flex point alternatives to achieve additional energy efficiency in accordance with Section R401.2.1.

a. Climate Zone 4C is Climate Zone Marine 4.

b. The Total UA shall be calculated in accordance with Section R402.1.5 Total UA alternative.

c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be ≥ 75% Sensible Recovery Efficiency (SRE), ≤ 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be ≥ 50% Latent Recovery/Moisture Transfer (LRMT).

d. As defined by Section R403.3.7.

e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table R407.2.1 and shall be sized to serve 100% of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.

f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table R407.2.1 and shall be sized to serve 100% of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.

Reason: This proposal, submitted by the Northwest Energy Codes Group, provides an alternative to the Flex Point proposal submitted by the Energy Efficient Codes Coalition by requiring ten flex points for an efficiency increase of ten (10) percent over the base prescriptive codes. The Northwest pioneered the use of the prescriptive residential options that are currently in place in Washington, and formally were used in Oregon, and found them to be an effective method of increasing efficiency for residential construction using the prescriptive approach. This option does not require performance energy modeling or HERS verification which will increase its usefulness. This type of points-based option can also be easily implemented in the U.S. DOE REScheck software. This approach is also similar in structure to the Points Option code change proposal that has been submitted by the Northwest Energy Codes Group to C407 in the commercial provisions of the 2018 IECC. This proposal will provide more consistency between the IECC and the Washington State Residential Energy Code which is based on the IECC.

The purpose of this code change proposal is to improve overall residential building efficiency (heating, cooling and water heating energy) by roughly 10% and to create a scalable, flexible means of improving residential building efficiency for future IECC updates. Instead of requiring efficiency improvements to specific building components, the new “Flex Points” approach in Section R407 provides a multitude of options for builders to achieve the efficiency requirements of the IECC. This approach is also scalable according to a jurisdiction’s needs – states or localities who need additional energy savings to meet energy or climate policy goals can adjust the number of required points accordingly. Package- or points-based approaches have been used for several years in Washington and Oregon.

This proposal is similar to the Flex Points proposal for the 2018 IECC in overall structure, but the points table has been simplified and updated based on feedback received in the previous Code Development Cycle. Like the previous version, this proposal also includes alternative compliance pathways for builders who select the simulated performance alternative or the Energy Rating Index, and will bring roughly equivalent improvements to all three compliance paths.

This Flex Points proposal is cost-effective, since it includes a number of options to achieve 10 points that are cost-effective.

The Flex Points proposal will provide three distinct benefits for jurisdictions adopting the 2021 IECC:

1. This proposal meets a clear need for efficiency improvements in the model energy code now and in the future.

Although the IECC has made small efficiency gains in the 2015 and 2018 editions, major gains have plateaued. Buildings still consume an estimated
42% of the nation's energy, 54% of its natural gas, and 71% of its electricity. Governors, legislators, and mayors are increasingly turning to building energy codes to meet energy and climate goals, and those codes should continue to provide reasonable improvements going forward. The U.S. Conference of Mayors, in its fourth consecutive resolution on the subject, reiterated their “concerted support for putting future triennial IECC updates on a “glide path” of steady efficiency gains that will improve the efficiency performance of millions of U.S. residential, multi-family, and commercial buildings.” See 2018 U.S.C.M. Resolution 86 (June 11, 2018).

Several jurisdictions have already created or are in the process of creating package-based compliance paths or improved code provisions to meet their policy needs. The result is improved efficiency, but a lack of consistency in both format and requirements. Incorporating Flex Points into the 2021 IECC will not only provide a 10% boost in energy conservation but will also provide a realistic map for additional improvements going forward. And, by providing more uniform targets for the efficiency of building components, this proposal will contribute to economies of scale, potentially lowering prices for builders and ultimately consumers.

2. This proposal will provide maximum flexibility for builders to achieve improved efficiency.

Flex Points trusts that builders and design professionals will select the most cost-effective and sensible efficiency improvements for a given project. There are several alternatives for compliance in each climate zone, along with options to comply in a performance- or rating-based path. There are alternatives related to more insulation, more efficient windows, reduced air and duct leakage and improved equipment. We believe that this approach provides the right incentives for builders to make long-lasting improvements in residential buildings that are in the best interests of homeowners.

The point values have been calculated based on the present value of energy cost savings over the current code (including relevant federal equipment efficiency standards) and reflect the estimated useful life of each measure over an assumed 30-year life of the building. While a 30-year period is consistent with the typical life of a mortgage, it is a very conservative period given the likelihood that some measures will provide efficiency benefits for decades beyond the initial 30-year period.

The analysis behind the flex points is based on the methodology and assumptions included in the U.S. Department of Energy’s Methodology for Evaluating Cost-Effectiveness of Residential Energy Code Changes, including the economic equations to obtain the present value of energy costs within the calculation methodology. The energy consumption calculations take into consideration heating, cooling, and water heating energy, using DOE-2 energy simulation across 105 TMY3 weather locations and 12 building types to account for varying stories, foundations, and fuel types for each of the baseline and upgrade measures. The analysis compares the annual energy savings between a home with and without an efficiency measure over the useful life of the efficiency measure using useful life data from NAHB and other sources. Energy costs were calculated using the most recent national EIA projections for natural gas and electricity. Because the analysis uses readily-available and widely-accepted tools and methodologies, we expect that future additions or changes will be straightforward.

3. This proposal will encourage efficiency improvements in building components that are currently difficult to regulate.

Flex Points addresses two issues that have complicated model energy codes for many years. First, innovative building practices or emerging technologies can benefit from being listed in codes, but states (and national code developing organizations) are reluctant to require new technologies or practices before they are market-tested. As a result, there are high barriers to entry for new technologies, even when they could transform the marketplace and provide energy- or cost-saving benefits for homeowners. As an example, Heat Recovery Ventilators (HRVs) are cost-effective and reasonable for much of the country, but individual circumstances or climate conditions may favor another approach. Rather than require HRVs in every case, or most cases with exceptions, HRVs and Energy Recovery Ventilators are included as one of several options available to builders in every climate zone. Not only will Flex Points create an opportunity for good technology to be used in more buildings, but it will open the door for market forces to make these technologies more widely available (and presumably less expensive to consumers). As new technologies or practices become available, these advances can be quickly and easily added into the Flex Points table, fast-tracking technology that is good for consumers.

Second, much of the heating, cooling, and water heating equipment installed in residential buildings is subject to federal preemption under the National Appliance Energy Conservation Act. As has been debated at length in ICC Code Development hearings over the last 15 years, including equipment efficiencies in performance trade-offs tends to weaken the efficiency of the energy code, since federal minimum efficiencies for nearly every covered product is well below the efficiency levels of commonly installed products. When these efficiency levels are used in trade-off baselines, builders use the improved efficiency of common heating, cooling, and water heating products as a means of trading away efficiency of more permanent building components and features, even though the equipment would have been installed anyway. This “free ridership” may provide short-term cost savings for homebuilders, but it saddles homeowners with unexpected high energy costs over the entire useful life of the building. Moreover, this equipment often carries a much shorter useful life, which is not typically captured in code compliance simulations.

Flex Points creates a new incentive to improve the efficiency of covered products without resulting in efficiency rollbacks elsewhere in the code. Heating, cooling, and water heating improvements (among others) are included among the Flex Points options with points calculated according to climate-specific energy cost savings and the longevity of the equipment. As compared to the previous Flex Points proposal, the list of options has been simplified and refocused on the equipment most likely to provide meaningful energy savings. Each of these upgrades will build upon the current IECC efficiency, rather than trading it away.

In sum, we believe that this proposal will improve efficiency by roughly 10% while unlocking the competitive market for new technologies or building
components that are difficult to regulate and will provide a useful new tool for policymakers across the country – all without rolling back the effectiveness or efficiency of the IECC.

**Bibliography:** *Uniting Cities to Accelerate Focus on the Economic and Climate Benefits of Boosting America's Building Energy Efficiency*, 2019

**Cost Impact:** The code change proposal will increase the cost of construction.
The code change proposal will increase the cost of construction. Requiring additional efficiency measures, such as more insulation, more efficient windows, reduced air leakage and duct leakage, and/or more efficient equipment, to save 10% energy will increase the cost of construction, but the resulting energy and cost savings will recoup the initial costs and will continue to benefit consumers over the useful life of the home.

Proposal # 5152
RE207-19
RE208-19
IECC: R401.2 (IRC N1101.13), R407 (IRC N1107) (New), R407.1 (IRC N1107.1) (New), Table R407.1 (IRC N1107.1) (New), R407.2 (IRC N1107.2) (New)

Proponent: Amanda Hickman, The Hickman Group, representing The Leading Builders of America (LBA) (amanda@thehickmangroup.com)

2018 International Energy Conservation Code

Revise as follows:

R401.2 (IRC N1101.13) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404 and Section R407
2. Section R405, Section R407 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Add new text as follows:

R407 (IRC N1107) ADDITIONAL ENERGY EFFICIENCY REQUIREMENTS

R407.1 (IRC N1107.1) Scope. This section establishes options for additional criteria to be met for one- and two-family dwellings and townhouses, as defined in Section 101.2 of the International Residential Code to demonstrate compliance with this code.

Exception: These requirements shall not apply to:

1. Homes complying under the Energy Rating Index (R406)
2. Alterations, renovations and repairs to an existing building
3. Additions with a conditioned floor area of less than 1,200 square feet.

R407.2 (IRC N1107.2) Requirements. In order to comply with this code:

1. Building utilizing the prescriptive path to comply with this code shall also comply with sufficient energy efficiency options from Table R407.1 in order to achieve a minimum of 3 energy credits.
2. Building utilizing the performance path to comply with this code shall use an adjusted annual energy cost that is 97% of the annual energy cost of the standard reference design when calculating Performance-based compliance (R405.3).

</tbody>
</table>

- Only one item in each Category can be counted.
- CZ4 includes Climate Zone 4 except Climate Zone 4 Marine.
- CZ5 includes Climate Zone 5 and Climate Zone 4 Marine.
- R-values are minimum averages.
- U-factors and SHGC are maximum weighted averages (exception: SHGC permitted to be higher in climate zones 5-8).
- Building tightness and duct tightness are maximum.
- Effectiveness, AFUE, SEER, HSPF, EF are minimums.
- Cells containing a dash (-) indicate zero credits because that measure is the baseline requirement or was not shown to improve energy savings.
- For any measure where the installed efficiency value falls between two thresholds from the table, credit shall be taken for the highest threshold that the installed value meets or exceeds.
- Measured leakage is outside conditioned space.
- Radiant Barriers shall comply with with IBC Section 1509 and shall be installed over the entire roof deck over conditioned space.

### Heating Systems

For other than electric heating without a heat pump: as proposed. Where the proposed design utilizes electric heating without a heat pump, the standard reference design shall be an air source heat pump meeting the requirements of Section C403 of the IECC – Commercial Provisions.

- **Capacity**: sized in accordance with Section R403.7.
- **Fuel Type/Capacity**: Same as proposed design.
- **Efficiencies**:
  - Electric: air source heat pump complying with prevailing federal minimum standards.
  - Nonelectric furnaces: natural gas furnace complying with prevailing federal minimum standards.
  - Nonelectric boilers: natural gas boiler complying with prevailing federal minimum efficiencies.

### Cooling Systems

As proposed. Capacity: sized in accordance with Section R403.7.

- **Fuel Type/Capacity**: Same as proposed design.
- **Efficiency**: complying with federal minimum standards.

### Service Water Heating

As proposed. Use: same as proposed design.

- **Use**: gal/day = 30 + 10 x Nbr
- **Tank temperature**: 120°F

### Thermal Distribution Systems

- **Duct insulation**: in accordance with Section R403.3.1.
- **Thermal distribution system efficiency (DSE)** of 0.88 shall be applied to both the heating and cooling system efficiencies for all systems other than tested duct systems.

**Exception**: For nonducted heating and cooling systems that do not have a fan, the standard reference design thermal distribution system efficiency (DSE) shall be 1.

For tested duct systems, the leakage rate shall be 4 cfm (113.3 L/min) per 100 ft² (9.29 m²) of conditioned floor area at a pressure of differential of 0.1 inch w.g. (25 Pa).

**Duct insulation**: as proposed.

### Thermostat

- **Type**: Manual, cooling temperature setpoint = 75°F; heating temperature setpoint = 72°F.

### Footnotes

- °C = (°F - 32)/1.8, 1 degree = 0.79 rad.

#### Additional Notes

- Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent, shall be used to determine the energy loads resulting from infiltration.

c. Thermal storage element shall mean a component that is not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

d. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

e. For a proposed design without a proposed heating system, a heating system having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

f. For a proposed design home without a proposed cooling system, an electric air conditioner having the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

g. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater having the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For a proposed design without a proposed water heater, a 40-gallon storage-type water heater having the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

h. For residences with conditioned basements, R-2 and R-4 residences, and for townhouses, the following formula shall be used to determine glazing area:

\[ AF = A_F \times FA \times F \]

where:

- \( AF = \) Total glazing area.
- \( A_F = \) Standard reference design total glazing area.
- \( FA = \) (above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 \times below-grade boundary wall area).
- \( F = \) (above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.

and where:

- Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.
- Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.
- Below-grade boundary wall is any thermal boundary wall in soil contact.
- Common wall area is the area of walls shared with an adjoining dwelling unit.

L and CFA are in the same units.

Reason: This proposal introduces a new section within the code that will require additional efficiency measures (options) for residential buildings. When taking the prescriptive approach, options from the table with assigned credit values must be selected in order to achieve 3 credits. For the performance approach, the same number of percentage number will reduce the annual energy cost for the standard reference design. The ERI path has not been included in this proposal as it is currently the most stringent path in the code.

The energy efficiency measures listed in Table 407.1 were analyzed using Ekotrope Rater modeling software (v3.1.0) to estimate energy savings relative to a 2018 IECC prescriptive reference house baseline. The energy modeling was performed by Home Innovation Research Labs. For all building characteristics not defined in the IECC, the “Methodology for Calculating Energy Use in Residential Buildings” was followed. This Methodology was developed in 2012 by Home Innovation Research Labs (formerly NAHB Research Center) to provide guidance, uniformity, and practical construction and equipment choices for researchers comparing the energy performance differences resulting from potential code changes.

A two-story single-family house (2,352 square feet above grade) was analyzed in 9 different locations across climate zones 1 through 7. For each location, multiple house configurations were analyzed to capture the effects of regionally-typical foundations and wall construction types. An all-electric house and a house with gas space heating and gas water heating were analyzed, resulting in 48 baseline designs for each of these configurations. Climate-appropriate energy conservation measures (ECMs) were analyzed individually for each unique house configuration for each location, resulting in more than 2,200 discrete designs covering all major aspects of building envelope construction, air tightness, equipment efficiencies and lighting and appliances. The credits in Table 407.1 were assigned as the weighted averages of the estimated whole-building energy savings (%) for each house configuration for the location. The weighting was based on regional market data. The credits are the result of weighted average whole-building energy savings rounded down to a 0.5% increment; except where the total energy savings ranged between 0.4% and 0.5%,
the values were rounded up to 0.5%.

In addition to individual measures, select packages of measures were also simulated for analysis across several climate zones. The comparison of additive energy savings from individual measures and the modeled net savings from packages of the same measures indicated that at the proposed 3% incremental levels of improvement, a simple addition of energy savings from individual measures is an adequate representation of their combined efficiency.

The energy performance target of 3% (or 3 credits) represents an incremental level of improvement that can be achieved through one or more compliance options (individual measures or a combination of measures) that meet the cost effectiveness metrics of simple payback of 10-15 years depending on the type of the measure.

The required credits and the paths to achieve these efficiency gains have been determined using current cost data provided by homebuilders from across the U.S. to have at a minimum a 10-year simple payback and to be cost effective when using the life cycle analysis method.

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal will increase the cost of construction. However, it has been determined, using current homebuilder cost data, that this proposal provides paths with at least a 10-year (or better) simple payback. This proposal has also been determined to be cost effective using the life cycle analysis method.
Revised 2019 International Energy Conservation Code

Revised as follows:

R401.2 Compliance. Projects shall comply with Section R401.2.1 and one of the following:

1. Sections R401 through R404.
2. Section R405 and the provisions of Sections R401 through R404 indicated as “Mandatory.”
3. The energy rating index (ERI) approach in Section R406.

Add new text as follows:

R401.2.1 Additional Energy Efficiency (Mandatory). This section establishes additional requirements applicable to all compliance approaches to achieve additional energy efficiency.

1. For buildings complying under Sections R401 through R404, one of the Additional Efficiency Package Options shall be installed according to Section R407.2.
2. For buildings complying under the simulated performance alternative in Section R405, the building shall meet one of the following:
   2.1. One of the Additional Efficiency Package Options in Section R407.2 shall be installed without including such measures in the proposed design under Section R405; or
   2.2. The proposed design of the building under Section R405.3 shall have an annual energy cost that is less than or equal to 95 percent of the annual energy cost of the standard reference design.
3. For buildings complying under the energy rating index alternative in Section R406, the energy rating index value shall be at least 5 percent less than the energy rating index target specified in Table R406.4.

The option selected for compliance shall be identified in the Certificate required by Section R401.3.

SECTION R407

ADDITIONAL EFFICIENCY PACKAGE OPTIONS

R407.1 Scope. This section establishes Additional Efficiency Package Options to achieve additional energy efficiency in accordance with Section R401.2.1.

R407.2 Additional Efficiency Package Options. Additional efficiency package options for compliance with Section R401.2.1 are set forth in Sections R407.2.1 through R407.2.5.

R407.2.1 Enhanced envelope performance option. The total building thermal envelope UA, the sum of U-factor times assembly area, shall be less than or equal to 95 percent of the total UA resulting from multiplying the U-factors in Table R402.1.4 by the same assembly area as in the proposed building. The UA calculation shall be performed in accordance with Section R402.1.5. The area-weighted average SHGC of all glazed fenestration shall be less than or equal to 95 percent of the maximum glazed fenestration SHGC in Table R402.1.2.

R407.2.2 More efficient HVAC equipment performance option. Heating and cooling equipment shall meet or exceed one of the following efficiencies:

1. Greater than or equal to 95 AFUE natural gas furnace and 16 SEER air conditioner.
2. Greater than or equal to 10 HSPF / 16 SEER air source heat pump.
3. Greater than or equal to 3.5 COP ground source heat pump.

For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in this section and shall be sized to serve 100 percent of the cooling design load. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in this section and shall be sized to serve 100 percent of the heating design load.

R407.2.3 Reduced energy use in service water heating option. The hot water system shall meet or exceed one of the following efficiencies:

1. Greater than or equal to 82 EF fossil fuel service water heating system.
2. Greater than or equal to 2.0 EF electric service water heating system.
3. Greater than or equal to 0.4 Solar Fraction solar water heating system.
R407.2.4 More efficient duct thermal distribution system option. The thermal distribution system shall meet or exceed one of the following efficiencies:
1. 100 percent of ducts and air handlers located entirely within the building thermal envelope.
2. 100 percent of ductless thermal distribution system or hydronic thermal distribution system located completely inside the building thermal envelope.
3. 100 percent of duct thermal distribution system located in conditioned space as defined by Section R403.7.

R407.2.5 Improved air sealing and efficient ventilation system option. The measured air leakage rate shall be less than or equal to 3.0 ACH50, with either an Energy Recovery Ventilator (ERV) or Heat Recovery Ventilator (HRV) installed. Minimum HRV and ERV requirements, measured at the lowest tested net supply airflow, shall be greater than or equal to 75 percent Sensible Recovery Efficiency (SRE), less than or equal to 1.1 W/CFM Fan Energy, and shall not use recirculation as a defrost strategy. In addition, the ERV shall be greater than or equal to 50 percent Latent Recovery/Moisture Transfer (LRMT).

Reason: The purpose of this code change proposal is to improve the energy efficiency of residential buildings by roughly 5% or more, and to provide code users with flexibility to select the measures that make the most sense for each project. This proposal largely mirrors the format of Section C406 Additional Efficiency Package Options—an approach to improving commercial buildings that has been included in the commercial energy code since the 2012 IECC. Like Section C406, new Section R407 offers multiple straightforward improvements that will increase energy savings and reduce costs to the homeowner over the useful life of the building. In addition, Section R401.2.1 provides two additional means of demonstrating compliance: 1) code users may achieve a 5% improvement in the performance path; or 2) code users may comply by applying a 5% improvement in ERI Target score. The range of options will provide multiple paths for projects to achieve the intended improvement in the code. The technologies included in the packages of improvements are currently available in the relevant markets and the improved building practices have been proven feasible in residential buildings. However, many of these measures would be difficult to include in the current code format because of federal preemption of covered products, inapplicability to certain home designs, or other limitations. This proposal follows the lead of states like Oregon and Washington that have successfully created a list of options available to builders to meet the residential code improvements. This approach increases flexibility for code users while advancing the code's efficiency baseline.

Although the historic energy efficiency gains in the 2009 and 2012 IECC have been largely maintained in the 2015 and 2018 IECC, there is a clear need for more substantial improvements in the 2021 IECC. It is well understood that buildings have an outsized impact on the nation’s energy demands. Buildings consume 42% of the nation’s energy, including 54% of the nation’s natural gas and 71% of its electricity. The nation’s policymakers are increasingly turning to building energy codes as a means of addressing energy and climate goals. Several states have adopted improvements beyond the 2018 IECC, and the U.S. Conference of Mayors recently called for “putting future triennial IECC updates on a ‘glide path’ of steady efficiency gains that will improve the efficiency performance of millions of U.S. residential, multi-family, and commercial buildings.” See 2018 U.S.C.M. Resolution 86 (June 11, 2018). While a much larger improvement in overall efficiency is warranted, a roughly 5% improvement through the adoption of this proposal would be a step in the right direction.

This proposal provides policymakers with additional options for improving the code going forward. A jurisdiction could increase the number of required options (and make a corresponding increase in the performance path and ERI required improvement). And as additional technologies and building methods become available, more options may be added to the initial list of improvements. (For example, Section C406 was expanded from 5 to 8 options in the 2018 IECC.) In sum, this proposal will allow the IECC to build upon recent improvements and create a new model for improving and adding flexibility to residential building energy codes going forward.

Cost Impact: The code change proposal will increase the cost of construction
For each climate zone, there are cost-effective options available that will generate energy savings and be cost effective over the useful life of the building. Although the savings will vary based on the option selected and design choices made in the building, there are multiple sensible options for achieving improved efficiency in each climate zone. On a broader scale, these improvements will help curb the nation's increasing demands for energy and contribute to a more secure energy future.
SECTION R407 (IRC N1107)
PATHWAY TO ZERO, ENERGY RATING INDEX COMPLIANCE ALTERNATIVE

R407.1 (IRC N1107.1) Scope. This section establishes criteria for jurisdictions to attain zero energy compliance using an Energy Rating Index (ERI) analysis by the year 2042.

R407.2 (N1107.2) Mandatory requirements. Compliance with this section requires that the provisions identified in Sections R401 through R404 indicated as “Mandatory” be met.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to an $R$-value of not less than $R$-8.

R407.3 (IRC N1107.3) Energy Rating Index. The Energy Rating Index (ERI) shall be determined in accordance with RESNET/ANSI/ICC 301 except for buildings covered by the International Residential Code, the ERI Reference Design Ventilation rate shall be in accordance with Equation 4-2.

Ventilation rate, CFM = (0.01 x total square foot area of house) + [7.5 x (number of bedrooms + 1)] (Equation 4-2)

Energy used to recharge or refuel a vehicle used for transportation on roads that are not on the building site shall not be included in the ERI reference design or the rated design.

R407.4 (IRC N1107.4) ERI-based compliance. Compliance based on an ERI analysis requires that the rated proposed design and confirmed built dwelling be shown to have a score less than or equal to the values in Table R407.4, for the ERI implementation date, when compared to the ERI reference design for each of the following conditions:

1. ERI value without on-site renewable energy generation
2. ERI value with on-site renewable energy generation

<table>

</tbody>
</table>

a. The maximum ERI without on-site renewables is fixed at an ERI of 40 after January 1st 2036, because thermal envelope and mechanical improvements cannot lower the ERI score significantly below that level.

b. The maximum ERI with on-site renewables can be achieved with or without installing onsite renewables until January 1st 2033 when on-site renewables are required to be used to lower the ERI below 40.

R407.5 (IRC N1107.5) Verification by an approved agency. Verification of compliance with the Section R407 as outlined in Section R407.4 and R407.6 shall be completed by an approved third party. Verification of Section R407.2 shall be completed by the authority having jurisdiction or an approved third party inspection agency per Section R105.4.

R407.6 (IRC N1107.6) Documentation. Documentation of the software used to determine the ERI and the parameters for the residential building shall be in accordance with Sections R407.6.1 through R407.6.3.
R407.6.1 (IRC N1107.6.1) Compliance software tools. Software tools used for determining ERI shall be approved software rating tools in accordance with RESNET/ICC 301.

R407.6.2 (IRC N1107.6.2) Compliance report. Compliance software tools shall generate a report that documents that the home and ERI score complies with Sections R407.2 through Section R407.4. The compliance documentation shall be created for the proposed design and submitted with the application for the building permit. Confirmed compliance documents of the built dwelling unit shall be created and submitted to the code official for review before a certificate of occupancy is issued. Compliance reports shall include information in accordance with Sections R407.6.2.1 and R407.6.2.2.

R407.6.2.1 (IRC N1107.6.2.1) Proposed Compliance report for permit application. Compliance reports submitted with the application for a building permit shall include the following:

1. Building street address, or other building site identification.
2. The name of the individual performing the analysis and generating the compliance report.
3. The name and version of the compliance software tool.
4. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. A certificate indicating that the proposed design has an ERI less than or equal to the appropriate scores indicated in Table R407.4 when compared to the ERI reference design. The certificate shall document the building component energy specifications that are included in the calculation including, component level insulation R-values or U-factors, assumed duct system and building envelope air leakage testing results, as well as the type and rated efficiencies of proposed heating, cooling, mechanical ventilation, and service water heating equipment to be installed. The type and production size of the proposed onsite renewable Energy systems shall be reported.
6. When a site-specific report is not generated, the proposed design shall be based on the worst-case orientation and configuration of the rated home.

R407.6.2.2 (IRC N1107.6.2.2) Confirmed Compliance report for a certificate of occupancy. A confirmed compliance report submitted for obtaining the certificate of occupancy shall be made site and address specific and include the following:

1. Building street address or other building site identification.
2. The name of the individual performing the analysis and generating the report.
3. The name and version of the compliance software tool.
4. If requested by the authority having jurisdiction, documentation of all inputs entered into the software used to produce the results for the reference design and/or the rated home.
5. A final confirmed certificate indicating that the confirmed design of the built home complies with Sections R407.2 and R407.4. The certificate shall report the energy features that were confirmed to be in the home including component level insulation R-values or U-factors, results from any required duct system and building envelope air leakage testing, as well as, the type and rated efficiencies of the heating, cooling, mechanical ventilation, and service water heating equipment installed. The type and production size of the confirmed onsite renewable energy systems shall be reported.

R407.6.3 (IRC N1107.6.3) Additional Documentation. The code official shall be permitted to require the following Documents:

1. Documentation of the building component characteristics of the ERI reference design.
2. A certification signed by the builder providing the building component characteristics of the rated design.
3. Documentation of the actual values used in the software calculation for the rated design.

R407.6.4 (IRC N1107.6.4) Specific Approval. Performance analysis tools meeting the applicable section of Section R407 shall be approved. Documentation demonstrating the approval of the performance analysis with Section R407.6.1 shall be provided.

R407.6.5 (IRC N407.6.5) Input values. Where calculation require input values not specified by Sections R402, R403, R404 and R405, those input values shall be taken from RESNET/ICC 301.

Reason: As the Energy Rating Index (ERI) diverges from the Home Energy Rating System Index (HERS) it becomes important to realize that although there are commonalities between the two, they are ultimately different from each other and should be thought of separately. As soon as the R406 ERI pathway was codified it locked in the ERI to a specific version of the RESNET/ANSI/ICC 301 standard while the HERS Index is based on a continually maintained version of the same ANSI 301 standard. Therefore, we now have divergent Index scores that mean different things. The HERS Index benchmarks the efficiency of a home in comparison to a reference home that is based on the 2006 IECC. A HERS Rating is an asset rating of the energy features in a home. This means that in the process of a HERS Rating to generate the HERS Index a Rater does not necessarily inspect to see if energy features governed by the code are installed according to requirements of the code. For example, the HERS Ratings systems’ insulation installation grading criteria gives guidance on how to de-rate the R-value of poorly installed insulation. The Rater is required to give a grade 3 to poor installations. The HERS Index score is intended to evaluate the performance of what is installed. It is not intended to determine if it was installed per the requirement of code. A code rating or evaluation for the generation of the ERI score, on the other hand, should only use a grade 1 because only grade 1 installation of insulation meets the requirements of manufacturer instructions and therefore code. If a Rater were to evaluate a home for an ERI score and come across grade 3 installation of insulation, the installation should fail the inspection and be re-installed to meet code requirements. In this way, an ERI rating and a HERS rating are fundamentally different. One is held to a pass/fail requirement of code and the other is a quantification and evaluation of energy assets or components of the home. This small example demonstrates how the HERS index score and the ERI score differ.
Another example that demonstrates a more pronounced difference between the indices is the codified ventilation requirements for the ERI score vs. the ventilation requirements for the HERS Index score. The ERI score uses the ASHRAE 62.2-2010 ventilation requirements while the HERS Index uses the ASHRAE 62.2-2013 ventilation requirements. This difference can result in over a 10-point difference in the scores.

Many are troubled by this divergence in the index scores, but I am not because the ERI and the HERS Index are fundamentally different if related systems. The HERS Index has been adopted by builders and the public primarily as a sales and marketing tool and a means to compare the performance of houses. The HERS Index score is quite good for these purposes. The ERI, like the area weighted u-values in section R402.1.5 Total U-factor Alternative, or cost comparison in section R405 Simulated Performance Alternative is a matrix by which a home’s performance can be compared to demonstrate compliance with the code. It is not intended for marketing or public consumption and as the scores continue to diverge the public will continue to be unaware of the ERI score just as they are unaware of area weighted u-values and cost compliance. If a common understanding can be created regarding this point then the ERI score can be a powerful tool to offer great flexibility for builders as well as a path forward for the code and municipalities who choose to use it to achieve greater energy efficiency.

This proposal has been designed to leverage the unique nature of the ERI and the already codified mandatory aspects of the IECC, so as to offer municipalities and builders an option that will continue the trend toward zero energy homes. As Section R407 is an optional pathway municipalities and builders can choose a code compliance path that allows great flexibility in energy specifications and design while the homebuilding industry learns how to incorporate new technologies or better use old ones. The IECC’s emphasis on protecting the thermal envelope is protected not by a punitive R-value backstop, but rather by a before renewables ERI requirement. A Pre-renewables ERI score opens up flexibility through cost-effective energy tradeoffs that are the most flexible for the builder as they would include mechanical, thermal or conductive, convective losses through envelope, along with duct tightness, lights, appliances, and more. Any feature that lowers the ERI can be used. This integrated energy evaluation acknowledges that the ERI of a home cannot be lowered beyond a certain threshold unless renewables are installed, but also sets the pre-renewable ERI at a level that ensures current levels of efficiency will be created as the starting point. For example, when a builder maximizes the thermal envelope and mechanical efficiencies of their design the ERI cannot go lower than approximately 35-40. To get an ERI score below that range on-site renewables must be installed. In this way, R407, as proposed, ensures a sound building envelope and efficient mechanical systems before renewables are considered.

The uniqueness of this proposal is that it creates a timeline by which a clear incremental approach for achieving increases in efficiencies that would lead to zero energy homes can be achieved. Although this will be new to the code development world, it is tremendously important to allow the path to zero to be phased in and for giving builders and jurisdictions a timeline for planning to achieve the ultimate goal. This phased-in approach has precedence in two Colorado jurisdictions. The City of Boulder and Boulder County have both set a phased approach for attaining zero energy in their municipalities.

Section R407 is optional so only those municipalities and builders that are searching for code compliant incremental approaches need take part. It has become a difficult argument to increase R-values, house tightness or duct leakage requirements in the 2021 IECC development cycle. This ERI approach to Zero Energy offers a logical, market-driven approach that creates a timeline for achieving significant increases in efficiency while simultaneously giving industry time to adjust and provide cost-effective solutions. This proposal also guards against building poor thermal envelopes and offsetting with on-site renewable systems. This proposal offers builders the greatest flexibility to choose how to build to meet the requirements of code.

Cost Impact: The code change proposal will increase the cost of construction

This R407 PATHWAY TO ZERO, ENERGY RATING INDEX COMPLIANCE ALTERNATIVE is just that and optional alternative pathway to not only demonstrate compliance with the IECC but to help jurisdictions that are interested define a measurable and incremental approach to create zero energy homes. This approach is being used in Colorado although it is true that cost of construction increases it is only required if the jurisdiction chooses to adopt the pathway.

Proposal # 5283

RE210-19
2018 International Energy Conservation Code

SECTION R501 (IRC N1107) GENERAL

R501.1 (IRC N1107.1.1) Scope. The provisions of this chapter shall control the alteration, repair, addition and change of occupancy of existing buildings and structures.

Revise as follows:

R502.1.1 (IRC N1107.1.1) Existing buildings. General Except as specified in this chapter, this code shall not be used to require the removal, alteration or abandonment of, nor prevent the continued use and maintenance of, an existing building or building system lawfully in existence at the time of adoption of this code. Unaltered portions of the existing building or building supply system shall not be required to comply with this code.

R502.1.4 (IRC N1107.4) R501 2 (IRC N1107.2) Compliance. Alterations, additions, repairs, additions or changes of occupancy to, or relocation of existing buildings and structures shall comply with the provisions for alterations, repairs, additions and changes of occupancy or relocation, respectively, in this code and the International Residential Code; International Building Code; International Existing Building Code; International Fire Code; International Fuel Gas Code; International Mechanical Code; International Plumbing Code; International Property Maintenance Code; International Private Sewage Disposal Code and NFPA 70, Sections R502, R503, R504, or R505 respectively in this code. Changes where unconditioned space is changed to conditioned space shall comply with Section R502.

SECTION R502 (IRC N1108) ADDITIONS

Revise as follows:

R502.1 (IRC N1108.1) General. Additions to an existing building, building system or portion thereof shall conform to the provisions of this code as those provisions relate to new construction without requiring the unaltered portion of the existing building or building system to comply with this code. Additions shall not create an unsafe or hazardous condition or overload existing building systems. An addition shall be deemed to comply with this code where the addition alone complies, where the existing building and addition comply with this code as a single building, or where the addition with the addition does not use more energy than the existing building. Additions shall be in accordance with Section R502.1.1 R502.2 or R502.1.2, R502.3

R502.2 (IRC N1109.2) R502.2 (IRC N1108.2) Change in space conditioning. Any nonconditioned or low-energy space that is altered to become conditioned space shall be required to be brought into full compliance with this code.

Exception Exceptions:

1. Where the simulated performance option in Section R405 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost otherwise allowed by Section R405.3.
2. Where unconditioned space is changed to conditioned space, and the building envelope of the addition shall comply with the Total UA, as determined in Section R402.1.5, of the existing building and the addition, and any alterations that are part of the project, is less than or equal to the Total UA generated for the existing building.
3. Where unconditioned space is changed to conditioned space, the addition shall comply with the annual energy cost or energy use of the addition and the existing building, and any alterations that are part of the project, is less than or equal to the annual energy cost of the existing building when modeled in accordance with Section R405. The addition and any alterations that are part of the project shall comply with Section R405 in its entirety.

R502.3 (IRC N1108.3) Prescriptive compliance. Additions shall comply with Sections R502.1.1 R502.3.1 through R502.1.4, R502.3.4

R502.1.1 (IRC N1108.1.1) R502.1.1 (IRC N1108.3.1) Building envelope. New building envelope assemblies that are part of the addition shall comply with Sections R402.1, R402.2, R402.3.1 through R402.3.5, and R402.4.

Exception: New envelope assemblies are exempt from the requirements of R402.4.1.2, Where unconditioned space is changed to conditioned...
space, the building envelope of the addition shall comply where the Total UA, as determined in Section R402.1.5, of the existing building and the addition, and any alterations that are part of the project, is less than or equal to the Total UA generated for the existing building.

R502.1.1.2 (IRC N1108.1.1.2) R502.3.2 (IRC N1108.3.2) Heating and cooling systems. New heating, cooling and duct systems that are HVAC ducts newly installed as part of the addition shall comply with Section R403.

Exception: Where ducts from an existing heating and cooling system are extended to an addition, duct systems with less than 40 linear feet (12.19 m) in unconditioned spaces shall not be required to be tested in accordance with Section R403.3.3.

R502.1.1.3 (IRC N1108.1.1.3) R502.3.3 (IRC N1108.3.3) Service hot water systems. New service hot water systems that are part of the addition shall comply with Section R403.4.

R502.1.1.4 (IRC N1108.1.4) R502.3.4 (IRC N1108.3.4) Lighting. New lighting systems that are part of the addition shall comply with Section R404.1.

R502.1.2 (IRC N1108.1.2) Existing plus addition compliance (Simulated Performance Alternative). Where unconditioned space is changed to conditioned space, the addition shall comply where the annual energy cost or energy use of the addition and the existing building, and any alterations that are part of the project, is less than or equal to the annual energy cost of the existing building when modeled in accordance with Section R405. The addition and any alterations that are part of the project shall comply with Section R405 in its entirety.

SECTION R503 (IRC 1109) ALTERATIONS

Revise as follows:

R503.1.2 (IRC N1109.1.2) Heating and cooling systems. New heating, cooling and duct systems that are part of the HVAC ducts newly installed, as part of an alteration shall comply with Section R403.

Exception: Where ducts from an existing heating and cooling system are extended, duct systems with less than 40 linear feet (12.19 m) in unconditioned spaces shall not be required to be tested in accordance with Section R403.3.3.

SECTION R505 (IRC N1111) CHANGE OF OCCUPANCY OR USE

Delete without substitution:

R505.1 General. Spaces undergoing a change in occupancy that would result in an increase in demand for either fossil fuel or electrical energy shall comply with this code.

Revise as follows:

R505.2 (IRC N1111.2) R505.1 (IRC N1111.1) General. Any space that is converted to a dwelling unit or portion thereof from another use or occupancy shall comply with this code.

Exception: Where the simulated performance option in Section R405 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost allowed by Section R405.3.

Add new text as follows:

R505.1.1 (IRC N1111.1.1) Nonconditioned Space Any nonconditioned or low-energy space that is altered to become a conditioned space shall comply with Section R502.

Reason: No advantage to any proprietary interests governed by the code is intended. The intent is strictly to make the IECC more understandable and easier to use; or, where technical change is proposed, to make the code more reasonable.

Unlike the bulk of proposed SEHPCAC changes this proposal does have two technical changes incorporated:

- It removes the requirement for additions to be air leakage tested per Sec. R402.4.1.2 Testing. It is unreasonable to expect an addition to comply with air leakage testing when it is likely open to existing, and potentially much older, unsealed residential space.
- It removes the requirement for duct leakage testing on duct extensions. It is unreasonable to expect the sealing of sections of older, potentially concealed, existing ducts from which new duct is to extend.

This change also:

- Clarifies changes from unconditioned space to condition space must comply as additions.
- Consolidates all compliance provisions related to changes from unconditioned to conditioned space.
This proposal is submitted by the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IgCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The two exemptions provided do not functionally change construction practices, neither the duct leakage of duct extensions and air leakage testing of envelope assemblies on additions is not feasible and therefore not current practice.
2018 International Energy Conservation Code

SECTION R502

ADDITIONS

Revised as follows:

R502.1 (IRC N1108.1) General. Additions to an existing building, building system or portion thereof shall conform to the provisions of this Code as those provisions relate to new construction without requiring the unaltered portion of the existing building or building system to comply with this Code unless required to do so by the chosen compliance pathway. Additions shall not create an unsafe or hazardous condition or overload existing building systems. An addition shall be deemed to comply with this Code where the addition alone complies, where the existing building and addition comply with this Code as a single building, or where the building with the addition does not use more energy than the existing building. Additions shall be in accordance with Section R502.1.1 or R502.1.2 by using either the prescriptive path in Section R502.1.1, simulated performance path in Section R502.1.2, or the energy rating index path in Section R502.1.3.

R502.1.1 (IRC N1108.1.1) Prescriptive Additions prescriptive compliance. Additions shall comply with Sections R502.1.1.1 through R502.1.1.4.

R502.1.1.1 (IRC N1108.1.1.1) Building envelope. New building envelope assemblies that are part of the addition alone shall comply with the prescriptive Sections R402.1, R402.2, R402.3.1 through R402.3.5, and R402.4.1.1.

Exception: Where unconditioned space is changed to conditioned space, the building envelope of the addition shall comply where the Total UA, as determined in Section R402.1.5, of the existing building and the addition, and any alterations that are part of the project, is less than or equal to the Total UA generated for the existing building.

R502.1.1.2 (IRC N1108.1.1.2) Heating and cooling systems. New heating, cooling and duct systems that are part of the addition shall comply with Section R403.

Exception: Where ducts from an existing heating and cooling system are extended to an addition, duct systems with less than 40 linear feet (12.19 m) in unconditioned spaces shall not be required to be tested in accordance with Section R403.3.3.

R502.1.1.3 (IRC N1108.1.1.3) Service hot water systems. New service hot water systems that are part of the addition shall comply with Section R403.4.

R502.1.1.4 (IRC N1108.1.1.4) Lighting. New lighting systems that are part of the addition shall comply with Section R404.1.

Revised as follows:

R502.1.2 (IRC N1108.1.2) Existing plus addition compliance (Simulated Performance Alternative). Cost compliance verification shall demonstrate that the existing building plus the addition does not use more energy than the existing building did prior to the addition. This method requires the project to create cost compliance verification at three stages:

1. A baseline cost compliance of the existing structure prior to construction.
2. Projected cost compliance of the existing building plus the addition based on the proposed design for the building in its entirety.
3. Confirmed cost compliance to verify whole building performance. Where unconditioned space is changed to conditioned space, the addition shall comply with the annual energy cost or energy use of the addition and the existing building, and any alterations that are part of the project, is less than or equal to the annual energy cost of the existing building when modeled in accordance with Section R405. The addition and any alterations that are part of the project shall comply with Section R405 in its entirety.

Add new text as follows:

R502.1.2.1 (IRC N1108.1.2.1) Reporting. Both the baseline and the projected cost compliance reports that include documentation of the proposed design shall be submitted with the construction documents. A confirmed cost compliance report shall be submitted prior to final inspection.

R502.1.3 (IRC N1108.1.3) Existing plus addition compliance (Energy Rating Index Alternative). An energy rating index score shall demonstrate that the existing building plus the addition does not use more energy than the existing building did prior to the addition. This method requires the project to obtain an ERI score at three stages:

1. A baseline ERI of the existing structure prior to construction.
2. A projected ERI of the existing building plus the addition based on the proposed design for the building in its entirety.
3. A confirmed ERI to verify whole building performance.

R502.1.3.1 (IRC N1108.1.3.1) Reporting. Both the baseline and the projected ERI compliance reports that include documentation for the proposed design shall be submitted with the construction documents. A confirmed ERI report shall be submitted prior to final inspection.

R502.1.4 (IRC N1108.1.4) Existing plus addition compliance (Prescriptive). The existing building plus the addition shall demonstrate that the structure in its entirety does not use more energy than the existing building did prior to adding the addition. All prescriptive measures shall be installed in the addition in accordance Section R402.1. A blower door test shall be performed to establish a baseline air leakage rate for the existing building prior to construction. Prior to final building inspection, a blower door test shall be conducted on the existing building plus addition to demonstrate an air leakage rate equal to or less than the baseline measurement.

R502.1.4.1 (IRC N1108.1.4.1) Reporting. A baseline blower door testing report for the existing building prior to construction shall be submitted with the construction documents. A confirmed blower door testing report shall be submitted after construction is complete and prior to final inspection.

Reason: The current existing buildings chapter 5 of the IECC has always struggled with clearly executing the energy code provisions on additions to an existing building. A building science approach teaches us that the house is a system. Therefore, if an addition is added to an existing building then the system's configuration has changed and assessing compliance on a portion of the system becomes a problem. In reality, it is not possible to assess a portion of the system separated from its entirety for energy code compliance. However, the code has established a method, but not a clear means for trying to do so.

In one form or another the IECC has always stated that an addition shall be deemed to comply where the building with the addition does not used more energy than the existing building did without the addition. The proposal for this section leverages this language (or method) and the existing paths (the means) in the code to offer better compliance mechanisms. The proposed Section R502.1.4 Existing plus addition compliance (Prescriptive), for example, uses a baseline pre-blower door test compared to a final confirmed blower door test to demonstrate if the final product is better than or equal to the existing benchmarking building. The assumption is that the prescriptive R-values, U-values, and installation requirements for the specification installed in the addition will be better than what has been installed in the existing portions of the building. Since it is not practical and, in most cases, possible to perform a blower door on just the addition the requirement changes in order to use the blower door as a compliance mechanism.

A Simulated Performance and Energy Rating Index path have been added as alternative compliance mechanisms in this section of the code for three reasons. First, the blower door is moved back to an assessment of energy performance rather than used as a compliance mechanism. Second, it is our experience that existing portions of a building are almost always touched during the creation of an addition on a building. Therefore, these compliance paths look at the entirety of the building rather than just the addition. Third, design flexibility is achieved when one is not required to use every portion of the prescriptive specification outlined in the code. The clear ability to use tradeoffs in existing buildings fits better with the reality of construction in this arena. Forth, these two pathways enable and encourage pre-planning as well as offer a very clear matrix of compliance. The software analysis to generate the proposed design for the existing building plus the addition clearly projects if the new building in its entirety, will be better than or equal to the existing benchmarked building. The projection enables the designer to forecast what in the existing building must be addressed which helps create better building budgets and expectations. In addition, a variety of options can be presented to pick what in the existing and new sections of the building makes the most sense to address.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Demonstration of compliance with this code is required regardless, so adding additional options for demonstrating compliance would not add to the cost. It is not a certainty, but added flexibility could reduce the cost of construction as well as jurisdictional time spent on enforcement.
SECTION R503 (IRC N1109)
ALTERATIONS

R503.1 (IRC N1109.1) General. Alterations to any building or structure shall comply with the requirements of the code for new construction. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as they relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall not create an unsafe or hazardous condition or overload existing building systems. Alterations shall be such that the existing building or structure does not use more energy than the existing building or structure prior to the alteration. Alterations to existing buildings shall comply with Sections R503.1.1 through R503.2.

R503.1.1 (IRC N1109.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section R402.1.2 or R402.1.4, Sections R402.2.1 through R402.2.13, R402.3.1, R402.3.2, R402.4.3 and R402.4.5. A pre and post blower door test shall be completed when building thermal envelope alterations are performed. If the alteration results in a post blower door CFM50 measurement that is less than the building airflow standard as set forth in Section R402.4.1.2, then combustion safety testing shall be performed and mechanical ventilation shall be recommended.

Exception: The following alterations shall not be required to comply with the requirements for new construction provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
3. Construction where the existing roof, wall or floor cavity is not exposed.
4. Roof re-cover.
5. Roofs without insulation in the cavity and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing.
6. Surface-applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided that the code does not require the glazing or fenestration assembly to be replaced.

Reason: Alterations to the buildings thermal envelope inevitably impact the air tightness of the building and therefore the combustion safety of the building. This section of the code is in existing buildings which is an indication that the majority of the structures have atmospherically vented appliances. Specifically, atmospherically vented water heaters, which are the most likely appliance to back draft, are susceptible to pressure changes in existing homes. Replacing windows, adding insulation, installing air tight IC rated can lights, or any individual building thermal envelope upgrade, changes the dynamic in the building significantly to warrant preventative combustion safety testing and possibly mechanical ventilation. The proposed language continues to demonstrate the importance of energy codes relationship to health safety and durability as well as efficiency as described in the code’s intent Section R101.3.

Cost Impact: The code change proposal will increase the cost of construction. Cost would be impacted as the health and safety of the building to better ensure that the occupant was not poisoned by carbon monoxide would have to be tested. This test cost approximately $200-400 if conducted as a stand-alone test. Many energy retrofit specialists and building envelope specialists include this test as part of their service which brings down the cost.
2018 International Energy Conservation Code
Revise as follows:

R502.1.1.1 (IRC N1108.1.1.1) Building envelope. New building envelope assemblies that are part of the addition shall comply with Sections R402.1, R402.2, R402.3.1 through R402.3.5, and R402.4.

Exception: Where unconditioned space is changed to conditioned space, the building envelope of the addition shall comply where the Total UA, as determined in Section R402.1.5, of the existing building and the addition, and any alterations that are part of the project, is less than or equal to the Total UA generated for the existing building.

Reason: This section of the code is talking about additions, which is new construction. The exception is talking about a change in space conditioning, which takes place as an alteration not as new construction. It does not make sense to have this exception for additions.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The exception wasn't addressing additions to begin with, so there should be no cost to remove it.
Proponent: Shauna Mozingo, City of Westminster, representing Colorado Chapter of ICC Energy Code Development Committee (smozingo@cityofwestminster.us)

2018 International Energy Conservation Code

Revise as follows:

R503.1 (IRC N1109.1) General. Alterations to any building or structure shall comply with the requirements of the code for new construction, without requiring the unaltered portions of the existing building or building system to comply with this code. Alterations shall be such that the existing building or structure is not less conforming to the provisions of this code than the existing building or structure was prior to the alteration. Alterations to an existing building, building system or portion thereof shall conform to the provisions of this code as they relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this code.

Alterations shall not create an unsafe or hazardous condition or overload existing building systems. Alterations shall be such that the existing building or structure does not use more energy than the existing building or structure prior to the alteration. Alterations to existing buildings shall comply with Sections R503.1.1 through R503.2.

Reason: Removing redundant language.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Removing redundant language.
IECC: R503.1.1.1 (IRC N1109.1.1.1)

Proponent: Shaunna Mozingo, representing Self (smozingo@cityofwestminster.us)

2018 International Energy Conservation Code

Revise as follows:

R503.1.1.1 (IRC N1109.1.1.1) Replacement fenestration. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for $U$-factor and SHGC as specified Table R402.1.2. Where more than one replacement fenestration unit is to be installed, an area-weighted average of the $U$-factor, SHGC or both of all replacement fenestration units shall be an alternative that can be used to show compliance.

Where fenestration was previously used as a trade off in the building thermal envelope, the replacement fenestration shall have a $U$-Factor and SHGC equal to or less than the original fenestration $U$-Factor and SHGC.

Reason: If someone used good windows to get out of some insulation or to lower the insulation value and then they go to replace the windows but only used today's code value there is a chance that they are making the building thermal envelope less conforming than it was at the time of construction. Section 503.1 says that an alteration can never make a structure less conforming or use more energy. This can be easily enforced if a jurisdiction requires the mandatory certificates that are called out in R401.3 that let us know what $U$-Factors and SHGC went in to the thermal envelope. These certificates become more and more important as we alter our buildings and as we provide trade offs such as window replacements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Because the energy code says that you can never make a building less conforming or use more energy, this new wording has always been implied but never written. Therefore, there should be no change in cost.
RE217-19
IECC: R503.1.1 (IRC N1109.1.1)

Proponent: Darren Meyers, P.E., IECC_LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code

Revise as follows:

R503.1.1 (IRC N1109.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section R402.1.2 or R402.1.4, Sections R402.2.1 through R402.2.13, R402.3.1, R402.3.2, R402.4.3 and R402.4.5.

Exception: The following alterations shall not be required to comply with the requirements for new construction provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
3. Construction where the existing roof, wall or floor cavity is not exposed.
4. Roof re-cover.
5. Roofs without insulation in the cavity and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing. Roof replacement, where the required R-value of insulation entirely above the roof deck cannot be provided due to thickness limitations presented by existing rooftop conditions, including an HVAC system or refrigeration equipment, skylight curb(s), low door or glazing heights, weep holes, parapet or roof flashing heights, the maximum approved thickness of insulation compatible with the available space and existing uses shall be installed.
6. Surface-applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided that the code does not require the glazing or fenestration assembly to be replaced.

Reason: This proposal is based on CE287-16, and resubmitted for flat-roof residential applications where the required R-value of insulation entirely above the roof deck cannot be provided due to thickness limitations. CE287-16 received a Committee recommendation of “Disapproval,” a Public Comment recommendation of “As Modified by Public Comment” (AMPC), but ultimately did not receive the two-thirds necessary to prevail during the “Online Governmental Consensus Vote” (OGCV), leading to “Disapproval” as its Final Action.

Specifically, the newly proposed exception addresses the AMPC and the challenge of constructability when installing additional roof insulation in reroofing situations including roof cover and roof replacement where existing conditions do not allow for the full thickness of insulation required by Table R402.1.2 or Table R402.1.4. Consider the square footage of residential buildings with flat roofs (i.e., “two-flats” and “three-flats”) constructed before an adoption of the 2009 IECC, that now require reroofing, without adequate “clear space” to accommodate up to 5+ inches (R-25-ish) or 6+ inches (R-30-ish) of insulation as the IECC evolved thru 2012 to 2015 and now the 2018 Editions. The building stock now considered 10 to 20 to 30+ years old, is far more likely to avail itself of skylight and structural curb heights, scupper and sump depths, door and window access thresholds that would turn into ponds, if five to six inches of insulation were “retroactively” foisted upon building ownership.

Moreover, if the IECC CDC were to consult the premise to Section R505.1, that “... [neither] an increase in demand for either fossil fuel [nor] electrical energy shall comply with this code,” so long as the current level of insulation in the roof is replaced with an equivalent thickness/level/R-value of NEW! insulation product, you’d likely conclude that he newly proposed Exception 5 is a “do-no-harm” proposition.

Should the Committee agree with the newly proposed Exception 5, then the continuance of current Exception 5 is unnecessary, as both the current Exception 4 (Roof re-cover) and the New! Exception 5 (Roof replacement) address all circumstances defined as Reroofing.

We believe the proposal makes clear that the maximum thickness of insulation compatible within the technically-feasible limitations of “available space” and maintaining “positive drainage” is to be installed.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change better positions the IECC to be clearer, more easily applied to reroofing, more competitive than the 90.1 Standard alternative on this issue; thereby no cost impact when compared with current provisions.

Proposal # 5271
RE218-19
IECC: R503.1.4

Proponent: Marilyn Williams, representing National Electrical Manufacturers Association (mar_williams@nema.org)

2018 International Energy Conservation Code
Revise as follows:

R503.1.4 (IRC N1109.1.4) Lighting. New lighting systems that are part of the alteration shall comply with Section R404.1.

   Exception: Alterations that replace less than 50% of the luminaires in a space, provided that such alterations do not increase the installed interior lighting power.

Reason: Revising this language will:
1. Increase energy efficiency
2. Reduce inconsistency and application confusion in compliance
3. Resolve compliance with application, approval and inspection.

This revised language aligns the residential lighting alteration section with the commercial lighting systems Section C503.6. It changes the lighting alteration exception from when less than 50 percent of the luminaires in the space are replaced, to when less than 10 percent are replaced. This will make compliance and usability of the code easier as well as increase in the energy efficiency of alterations when 10 or less than 50 percent of the luminaires are replaced.

Cost Impact: The code change proposal will increase the cost of construction
This code change proposal will increase the cost of construction for residential alterations that replace between 10 and 50 percent of luminaires in a space.
RE219-19
IECC: R503.1.1 (IRC N1109.1.1)

Proponent: Darren Meyers, P.E., IECC LLC representing the National Roofing Contractors Association, representing the National Roofing Contractors Association (dmeyers@ieccode.com)

2018 International Energy Conservation Code
Revise as follows:

R503.1.1 (IRC N1109.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section R402.1.2 or R402.1.4, Sections R402.2.1 through R402.2.13, R402.3.1, R402.3.2, R402.4.3 and R402.4.5.

Exception: The following alterations shall not be required to comply with the requirements for new construction provided that the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
3. Construction where the existing roof, wall or floor cavity is not exposed.
4. Roof re-cover.
5. Roofs without insulation in the cavity entirely above the roof deck and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing.
6. Surface-applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided that the code does not require the glazing or fenestration assembly to be replaced.

Reason: It is unclear as to the intended application of current Exception 5 to Section 503.1.1. We believe the Exception was intended to apply to low-slope roof reroofing, as defined. However, with all roof re-covers addressed by current Exception 4, it is therefore likely current Exception 5 was intended to apply solely to flat roof replacement operations.

The overall outcome (i.e., fate) in applying Exception 5 to a low-slope roof replacement is seemingly to advise the roofing contractor to install replacement insulation, at whichever thickness and R-value (i.e., recall this is an exception), either above or below the rafter-line.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

There is no cost implication aligned with this proposal. Rather, it is an exercise steeped in clarification and consistency across the ICC Family of International Codes.
2018 International Energy Conservation Code
Revise as follows:

SECTION R503 (IRC N1109)
ALTERATIONS

R503.2 (IRC N1109.2) Change in space conditioning. Any nonconditioned or low-energy space that is altered to become conditioned space shall be required to be brought into full compliance with this code.

Exception: Where the simulated performance option in Section R405 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost otherwise allowed by Section R405.3. Spaces where compliance is demonstrated using the compliance mechanisms in accordance with Section R502.

SECTION R505 (IRC N1111)
CHANGE OF OCCUPANCY OR USE

R505.2 (IRC N1111.2) General. Any space that is converted to a dwelling unit or portion thereof from another use or occupancy shall comply with this code.

Exception: Where the simulated performance option in Section R405 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost allowed by Section R405.3. Spaces where compliance is demonstrated using the compliance mechanisms in accordance with Section R502.

Reason: This proposed change to Alteration and Change of Occupancy or Use in this existing buildings chapter offers a more flexible alternative compliance paths as outlined in the proposal for prescriptive, simulated performance, and energy rating index compliance paths in the Additions section of Section R505 Existing Buildings Performance Compliance Alternative. If the proposal is not accepted this proposal will be removed from consideration.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Demonstration of compliance with this code is required regardless, so adding additional options for demonstrating compliance would not add to the cost. It is not a certainty, but added flexibility could reduce the cost of construction as well as jurisdictional time spent on enforcement.
2018 International Energy Conservation Code

Revise as follows:

R505.1 (IRC N1107.1) General. Spaces undergoing a change in occupancy that would result in an increase in demand for either fossil fuel or electrical energy shall comply with this code. R501.1.1.

R505.2 (IRC N1111.2) General. Any space that is converted to a dwelling unit or portion thereof from another use or occupancy shall comply with this code. Section 501.1.1.

Exception: Where the simulated performance option in Section R405 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost allowed by Section R405.3.

Reason: Sections R502.1 and R503.1 reference complying with the code for new construction without requiring unaltered portions of the building to "comply with this code". Section R503.2 requires the space to be brought in to "full compliance with this code". Section 505.1 and 505.2 say a space has to "comply with this code". What is all that saying?

Many building departments read all of them to say the same thing that you have to be brought in to full compliance with the code. But if you look at the scope of both of these sections, they all have a different intent. It's pretty clear that when dealing with additions and alterations you only have to fix what you touch. And it stands to reason in 503.2 that if you go from a building that didn't use energy to a building that does use energy you need to comply with the entire code. But when you get to a change of occupancy or use, the intent becomes less clear. It says you have to comply with the code but does that mean "full code" like stated in 503.2 or "this code" like stated in 502 and 503?

Because 505 is dealing with a space that has already been conditioned (or you would be in 503.2) and its dealing with a change, we feel that the intent is truly that these spaces must comply with the code as it relates to existing buildings. Therefore, we have removed the confusing language and inserted the section that tells you which sections of the code your existing building must comply with.

For those who interpreted this existing section to require all changes of occupancy or use to be brought in to full compliance they are not going to like allowing unaltered portions to not be brought in to full compliance. But, we would say it never had to be or the wording in 503.2 would have been carried over to 505. It is our intent that when changing an occupancy or use that increases the demand for either fossil fuel or electrical energy you only have to change what the appropriate sections require you to change.

Changes in space conditioning are so different than changes of use. There's a big difference between a building that never complied versus a building that complied when it was built and is now changing its use. If you require every change of use to be brought in to 100% compliance you are discouraging the re-use of existing buildings. It becomes cheaper to move in to a new building than to get the best we can out of an existing building and move on.

Cost Impact: The code change proposal will decrease the cost of construction

Complying with only specific sections referenced in Chapter 5 instead of the entire code will likely decrease the cost of construction.
2018 International Energy Conservation Code

Revise as follows:

RA103.1 (IRC AT103.1) General. New detached one- and two-family dwellings, and townhouses with not less than 600 square feet (55.74 m²) of roof area oriented between 110 degrees and 270 degrees of true north shall comply with Sections RA103.2 through RA103.8.

Exceptions:

1. New residential buildings with a permanently installed on-site renewable energy system.
2. A building with a solar-ready zone that is shaded where all areas of the roof that would otherwise meet the requirements of Section RA103 are in full or partial shade for more than 70 percent of daylight hours annually.

RA103.4 (IRC AT103.4) Obstructions. Solar-ready zones shall be free from obstructions, including but not limited to vents, chimneys, and roof-mounted equipment.

Add new text as follows:

RA103.5 (IRC AT103.5) Shading. The solar-ready zone shall be set back from any existing or new, permanently affixed object on the building or site that is located south, east or west of the solar zone a distance not less than 2 times the object's height above the nearest point on the roof surface. Such objects include, but are not limited to, taller portions of the building itself, parapets, chimneys, antennas, signage, roof top equipment, trees and roof plantings.

RA103.6 (IRC AT103.6) Capped Roof Penetration Sleeve A capped roof penetration sleeve shall be provided adjacent to a solar-ready zone located on a roof slope of not greater than 1 unit vertical in 12 units horizontal (8-percent slope). The capped roof penetration sleeve shall be sized to accommodate the future photovoltaic system conduit, but shall have an inside diameter of not less than 1 1/4 inches (32 mm).

Reason: The solar ready appendix in the IRC was changed last cycle but the changes were not incorporated in the solar ready appendix of IECC residential provisions. It was our understanding that anything dealing with residential provisions of the energy code would automatically match what was in the IRC, but apparently this does not apply to the appendix chapters. There is absolutely no reason that these two appendix chapters should differ.

Cost Impact: The code change proposal will increase the cost of construction. The cost of a roof penetration sleeve would be incurred if you were building to the IECC and had not been using the IRC. This would perhaps happen for multi family buildings less than 3 stories in height or for jurisdictions who use the IECC residential provisions and not the IRC.
2018 International Energy Conservation Code
Add new text as follows:

Appendix RB (IRC Appendix Q)
ZERO ENERGY RESIDENTIAL BUILDING PROVISIONS

RB102 (IRC AQ 102) COMPLIANCE (Note: language to replace R401.2 Compliance)
Existing residential buildings shall comply with Chapter 5. New residential buildings shall comply with Section RB103.

RB103 (IRC AQ 103)
ZERO ENERGY RESIDENTIAL BUILDINGS

RB103.1 (IRC AQ103.1) General. New residential buildings shall comply with Section RB103.

RB103.2 (IRC AQ103.2) Energy Rating Index Zero Energy Score. Compliance with this section requires that the rated design be shown to have a score less than or equal to the values in Table RB103.2 when compared to the ERI reference design determined in accordance with RESNET/ICC 301 for each of the following:

1. ERI value not including net onsite power production calculated in accordance with RESNET/ICC 301, and
2. ERI value including net onsite power production calculated in accordance with RESNET/ICC 301

a. The building shall meet the mandatory requirements of Section R406.2, and the building thermal envelope shall be greater than or equal to the levels of efficiency and SHGC in Table R402.1.2 or Table R402.1.4. of the 2015 International Energy Conservation Code.

Reason: This proposal provides cities and states an appendix to the residential section of the 2021 IECC that would result in a residential building that has zero energy consumption over the course of a year. Jurisdictions would have the prerogative to adopt the appendix in support of policy goals related to energy efficiency and renewable energy. The provisions contained in this appendix are not mandatory unless specified as such in the jurisdiction's adopting ordinance.

Why is this needed?

States and cities across the country are pursuing policies to reduce the energy consumption of buildings. More than 270 cities and counties and 10 states are signatories to the “We Are Still In” commitment supporting climate action to meet the goals of the Paris climate accord. Thus far, seventy cities have committed to being powered by 100% renewable energy and more are joining all the time. The building energy code is an important policy tool for jurisdictions as they pursue these types of policy goals.

Many of these energy and climate-related goals have a target year of 2030, so the time is ripe to provide this option in the model energy code. While jurisdictions already can modify the model code to meet their needs, many do not have the in-house expertise to develop and vet this type of code language. Integrating a zero energy building pathway into the 2021 IECC as a jurisdictional option will make the model energy code a more robust policy tool. Use of appendices in the IECC have proven successful with the solar provisions in the 2018 IECC appendices.
Including a zero energy building appendix in the model energy code can smooth the transition to zero energy for builders. Rather than jurisdictions going alone—leading to a patchwork of zero energy residential code approaches—a single IECC appendix would provide consistent national language across the residential industry for manufacturers, builders and trades. Builders can standardize their construction practices across jurisdictions and states to meet these requirements. This makes education, incentive programs, and implementation significantly more straightforward and cost-effective.

**How the Zero Energy appendix works**

While there are a number of definitions of “zero energy buildings” (also referred to as “zero net energy,” “net zero energy,” or simply, “net zero”), the Appendix is based on the Energy Rating Index (ERI) compliance path found in section R406 of the 2018 IECC. In principle, the proposal works as follows:

1. Required ERI values are based on a highly efficient energy use performance level before considering on-site power generation.

2. The remaining energy use, on an annual level, is satisfied with on-site power generation.

The Energy Rating Index scores are set for a highly efficient level of energy consumption, which importantly, is still cost effective for the homeowner. These scores, which range from 42 to 48 based on climate zone, were calculated based on a thorough analysis of HERS scores nationwide, a survey of HERS scores for model high-performance home, modeling done for ASHRAE 90.2, and the U.S. DOE Zero Energy Ready Home program.

On-site renewable energy capacity is then required to meet the remaining energy use, resulting in an Energy Rating Index score of zero. Software required in the RESNET 301 standard can easily generate an ERI score of the home before and after the inclusion of renewable energy (known as Onsite Power Production in HERS). All renewable energy is required to be on-site. The minimum envelope backstops required in section R406 are also required in this appendix. Homes may use any fuel in accordance with RESNET 301 to comply with the Appendix.

**Bibliography:**

**Cost Impact:** The code change proposal will increase the cost of construction

If adopted by the state or jurisdiction, complying with this appendix will increase the first cost of construction but the Energy Rating Index values, before the addion of onsite power production, that have been selected were found to be cost effective based on information presented to the ASHRAE Standard 90.2 committee. All of the ERI scores without onsite power production have been found to have Savings/Investment Ratios (SIR) of greater than 1.0.
RE224-19 Part I
PART I — IECC: APPENDIX RB (New)
PART II — IRC: APPENDIX U (New)

Proponent: Theresa Weston, representing DuPont Performance Building Solutions (theresa.a.weston@dupont.com)

THIS IS A 2 PART CODE CHANGE PROPOSAL. PARTS I AND II WILL BE HEARD BY IECC-RE COMMITTEE. PLEASE SEE THE TENTATIVE HEARING ORDERS FOR THIS COMMITTEE.

2018 International Energy Conservation Code
Add new text as follows:

Appendix RB
STRETCH ENERGY CODE PROVISIONS

SECTION RB101
GENERAL

RB101.1 Scope. The provisions of this appendix shall be applicable for new construction or portions of existing residential buildings undergoing renovation or addition where increased levels of energy efficiency are required.

SECTION RB102
REQUIREMENTS

RB102.1 Requirements. Residential buildings or portions of residential buildings shall meet the requirements of ASHRAE/IES Standard 90.2.

SECTION RB103
REFERENCE STANDARDS

Add new standard(s) as follows:

ASHRAE

Proposal # 5284

RE224-19 Part I
Appendix U
STRETCH ENERGY CODE PROVISIONS

SECTION AU101
GENERAL

AU101.1 Scope. The provisions of this appendix shall be applicable for new construction or portions of existing residential buildings undergoing renovation or addition where increased levels of energy efficiency are required.

Revise as follows:

SECTION AU102
REQUIREMENTS

AU102.1 Requirements. Residential buildings or portions of residential buildings shall meet the requirements of ASHRAE/IES Standard 90.2.

SECTION AU103
REFERENCE STANDARDS

Add new standard(s) as follows:

ASHRAE

Reason: Some jurisdictions are interested in adopting stretch energy codes. Providing a stretch code through the reference of ANSI/ASHRAE/IES Standard 90.2-2018 allows for a stretch code that is based on an ERI methodology that is compatible with the ERI pathway within the base IECC. The ERI levels specified within 90.2-2018 have been specified as Tier 3 within the CEE New Residential Construction Specification, while the IECC 2018 ERI path is specified as Tier 1. (https://library.cee1.org/content/cee-residential-new-construction-specification/)

Cost Impact: The code change proposal will increase the cost of construction
The cost of construction will increase in the jurisdictions which adopt the stretch code appendix, but Standard 90.2 has been analyzed to be cost effective. The cost effectiveness analysis is reported in FSEC-RR-584-15 Maximum Energy Efficiency Cost Effectiveness in New Home Construction, dated May 20, 2015 (available at http://www.fsec.ucf.edu/en/publications/pdf/FSEC-RR-584-15.pdf).

Staff Analysis: A review of the standard proposed for inclusion in the code, ASHRAE 90.2-2018, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
RE225-19
IECC: R403.2 (IRC N1103.2)

Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Energy Conservation Code

R403.2 (IRC N1103.2) Hot water boiler outdoor temperature setback. Hot water boilers that supply heat to the building through one- or two-pipe heating systems shall have an outdoor setback control that decreases the boiler water temperature based on the outdoor temperature.

Exception: Boiler systems also used for domestic water heating.

Reason: This proposal is a correlation to the IECC-C code proposal to provides clarity to the requirements.

Why is the proposed code change a reasonable solution? It clarifies an exception.

Cost Impact: The code change proposal will decrease the cost of construction
This code change exempts domestic water heating from adding these setback controls which costs money to install (and maintain). By not installing them on the domestic water heating system it will save on costs of equipment.

Proposal # 5113

ICC COMMITTEE ACTION HEARINGS :::: April, 2019
The following is the tentative order in which the proposed changes to the code will be discussed at the public hearings. Proposed changes which impact the same subject have been grouped to permit consideration in consecutive changes.

Proposed change numbers that are indented are those which are being heard out of numerical order. Indentation does not necessarily indicate that one change is related to another. Proposed changes may be grouped for purposes of discussion at the hearing at the discretion of the chair. Note that some GG code change proposals may not be included on this list, as they are being heard by another committee.

GG1-19
GG2-19
GG3-19
GG4-19
  ADM16-19 Part III
GG5-19
  ADM33-19 Part IV
  ADM40-19 Part V
2018 International Green Construction Code

SECTION 101
GENERAL

101.1 Title. These regulations shall be known as the Green Construction Code of [NAME OF JURISDICTION] hereinafter referred to as “this code.”

Revise as follows:

101.3.3 101.2 (2.3) General. This code is intended to provide minimum requirements to be used in conjunction with the other codes and standards adopted by the jurisdiction. The requirements in this code shall not be used to circumvent any applicable safety, health, or environmental requirements.

Delete without substitution:

101.2.2 (1.2) This code is intended to provide the technical basis of mandatory building codes and regulations for high-performance green buildings that are broadly adoptable by national and local jurisdictions.

Add new text as follows:

101.3 Scope. The provisions of this code shall apply to the design, construction, addition, alteration, change of occupancy, relocation, replacement, equipment, removal and demolition of every building or structure or any appurtenances connected or attached to such buildings or structures and to the building site on which the building is located. Occupancy classifications shall be determined in accordance with the International Building Code.

Delete without substitution:

101.3.1 (2.1) This code contains requirements that address site sustainability, water use efficiency, energy efficiency, indoor environmental quality (IEQ), materials and resources, and construction and plans for operation. This code applies only to the following building projects:

1. New buildings and their systems.
2. New portions of buildings and their systems.
3. New systems and equipment in existing buildings.
4. Relocated existing buildings and temporary structures where specified in this code.

Revise as follows:

101.3.2-101.3.1 (2.2) The provisions of this code do not apply to the following:

2. Multifamily dwellings of three stories or fewer above grade.
3. Manufactured houses (mobile homes).
4. Manufactured houses (modular).
5. Building projects that use none of the following:
   1. Electricity.
   2. Fossil fuels.
   3. Water.

(Informative note Exception: The provisions in Appendix J for residential and multifamily construction apply where adopted by the authority having jurisdiction.)

101.4.1(4.1) 101.4 (1.1) Intent. The purpose intent of this code is to provide minimum requirements for the siting, design, construction, and plans for operation of high-performance green buildings to: reduce emissions from buildings and building systems; enhance building occupant health and comfort; conserve water resources; protect local biodiversity and ecosystem services; promote sustainable and regenerative materials cycles; enhance building quality; enhance resilience to natural, technological, and human-caused hazards; and support the goal of development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

101.4.1(4.4) 101.5 General Compliance. Building projects shall comply with this code. Within each of Chapters 5 through 11, building projects shall comply with all mandatory provisions (x.3) and, where offered, either the:
1. Prescriptive Option (x.4) or
2. Performance Option (x.5).

**Reason:** This proposal correlates the standard ICC Chapter 1 language with the administration language contained in ASHRAE Standard 189.1. New Section 101.2 (General) is a standard ICC section. In the 2018 IgCC it was covered, in essence, by Sections 101.2.2 and 101.3.3.

New Section 101.3 (Scope) is standard ICC scoping language.

2018 IgCC Section 101.3.2 is renumbered (no change to text) as Section 101.3.1 and is retained as a list of what are essentially exceptions to the scope.

2018 IgCC Sections 101.2.1 and 101.3.1 (Purpose and Scope) are now more appropriately combined and retitled as Section 101.4, Intent.

"Informative Notes" are typical in ASHRAE standards; in this proposal the informative note is clearly indicated as what it actually is: an exception.

The provisions of 2018 IgCC Sections 101.2 and 101.2.1 (Purpose) and 101.3.1 (Scope) are more appropriately relocated and retitled as Section 101.3, Intent.

The title of new Section 101.5 has been changed from "Application/General" to "Compliance" to differentiate it from the Section 102, Applicability.

This proposal is submitted by the ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors in July of 2011 to pursue opportunities to improve and enhance the IECC, the IgCC and the energy provisions of the IRC. The SEHPCAC held 4 open meetings in 2018. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the SEHPCAC website at: https://www.iccsafe.org-tech-support/codes/code-development-process/sustainability-energy-and-high-performance-code-action-committee-sehpcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

This proposal reorganizes and clarifies the code. It does not create any technical changes that would affect construction costs.

Proposal # 5164
GG1-19
**GG2-19**

**IGCC®: 101.4 (New), Table 101.4 (New)**

**Proponent:** Jim Edelson, representing New Buildings Institute (jim@newbuildings.org)

**2018 International Green Construction Code**

Add new text as follows:

101.4 Mandatory Chapters. Building projects shall comply with Chapters 5 through 11, except for those Chapter(s) determined not to be mandatory where selected by the jurisdiction in Table 101.4.

**Table 101.4**

Mandatory Compliance Chapters Determined By the Jurisdiction

<table>

<td>No [ ]</td>
</tr>
</tbody>
</table>

**Reason:** Many jurisdictions that consider adopting IgCC first face the question of which areas of scope (chapters) will be applied, and how they will be administered within the jurisdiction - or even if they fall within their governing authority. It is most likely a combination of policy intentions, statutory authority, and cross-agency administration that is considered as the decision is made to select which IgCC chapters should be pursued for adoption.

The proposal adds a clear mandatory chapter selection table to the administrative provisions of Chapter 1 where it can easily be indicated which chapters of the IgCC will not be mandatory for compliance with the code.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code change provides a mechanism for jurisdictions to limit the scope of the IgCC, and does not in itself impact construction.
GG3-19
IGCC®: 101.4.1(4.1), Table 101.4.1 (New)

Proponent: David Collins, representing SEHPCAC (SEHPCAC@icc safe.org)

2018 International Green Construction Code
Revise as follows:

101.4.1(4.1) General. Building projects shall comply with Chapters 5 through 11. Within each of these chapters, building projects shall comply with all mandatory provisions (x.3) and, where offered, either the:

1. Prescriptive Option (x.4) or
2. Performance Option (x.5).

Exceptions:

1. Compliance shall not be required with Sections that are listed in Table 101.4.1 where the jurisdiction has opted out by checking “No” in the corresponding cell in the jurisdictional requirement column.
2. Where the jurisdiction has indicated a diversion percentage for Section 5.3.8.1 in Table 101.4.1, that percentage shall replace the diversion percentage indicated in Section 5.3.8.1.

Add new text as follows:

**Reason:** This proposal is intended to increase adoptions of the IgCC by allowing jurisdictions to customize the code so that it may be more acceptable to more of the parties affected. The proposal generally simplifies the code for owners, designers, manufacturers, code officials and elected officials by identifying provisions that may not be suitable in all locations and allowing jurisdictions to opt out of them. All other code sections are considered to be core requirements, suitable for all jurisdictions and critically important in order to be considered a green or sustainable building. The user of Chapter 7 is required to comply with ASHRAE 90.1-2016 which saves more energy than the requirements that many jurisdictions now require. Many of the requirements listed in Table 101.4 for Chapter 7 are beyond those in ASHRAE 90.1 for the same topic.
This proposal is submitted by the ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance the IECC, the IgCC and the energy provisions of the IRC. The SEHPCAC held 4 open meetings in 2018. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the SEHPCAC website at: https://www.iccsafe.org-tech-support/codes/code-development-process/sustainability-energy-and-high-performance-code-action-committee-sehpcac.

**Cost Impact:** The code change proposal will decrease the cost of construction.
Where jurisdictions opt-out of requiring compliance with code sections, construction costs decrease.
2018 International Green Construction Code

Delete without substitution:

101.4.2 (4.1.1) Referenced Standards. The standards referenced in this code and listed in Chapter 11 shall be considered to be part of the requirements of this code to the prescribed extent of such reference. Where differences exist between provisions of this code and a referenced standard, the provisions of this code shall apply. Informative references in Informative Appendix G are cited to acknowledge sources and are not part of this code.

101.4.3 (4.1.2) Normative Appendices. The normative appendices to this code are considered to be integral parts of the mandatory requirements of this code, which for reasons of convenience are placed apart from all other normative elements.

Revise as follows:

101.4.4 (4.1.3) Informative Appendices. The informative appendices to this code, and informative notes located within this code, contain additional information and are not mandatory or part of this code.

Exceptions:

1. Prescriptive Energy Compliance Option. Where the jurisdiction adopts the International Energy Conservation Code (IECC) based provisions of Appendix H for prescriptive energy compliance and that option is utilized on the building project, compliance with ANSI/ASHRAE/IES Standard 90.1 shall not be required.

2. Residential Compliance Option. Where the jurisdiction adopts the ICC 700 based provisions of Appendix J for residential compliance and that option is utilized on the building project, compliance with other provisions of this code shall not be required.

101.4.5 (4.1.4) Referenced Standard Reproduction Annexes. The referenced standard reproduction annexes contain material that is cited in this code but that is contained in another standard. The reference standard reproduction annexes are not part of this code but are included in its publication to facilitate its use.

102.4.1 Conflicting provisions. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code or the International Codes as adopted by the authority having jurisdiction listed in Section 102.4, the provisions of this code or the International Codes listed in Section 102.4, as applicable, shall take precedence over the provisions in the referenced code or standard.

102.4.2 Application of referenced standards. The standards referenced in this code and listed in Chapter 11 shall be considered to be part of the requirements of this code to the prescribed extent of such reference. Where differences exist between the provisions of this code and a referenced standard, the provisions of this code shall apply. Informative references in Informative Appendix G are cited to acknowledge sources and are not part of this code.

Reason: All but the last sentence of Section 101.4.2 was redundant with Section 102.4.2. Therefore, Section 101.4.2 was deleted except that the last sentence of Section 101.4.2 was added to Section 102.4.2.

Exceptions were added to Section 101.4.4 to address the fact that Appendices H (IECC based prescriptive energy compliance) and J (ICC 700 National Green Building Standard based residential compliance), unlike all other informative appendices, are adoptable and are only enforceable where they are adopted, as indicated at the top of the page of each of these appendices. Thus, these informative appendices become part of the code where they are adopted, which is contrary to the charging sentence in Section 101.4.4.

This proposal is submitted by the ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors in July of 2011 to pursue opportunities to improve and enhance the IECC, the IgCC and the energy provisions of the IRC. The SEHPCAC held 4 open meetings in 2018. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee, as well as interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the SEHPCAC website at: https://www.iccsafe.org-tech-support/codes/code-development-process/sustainability-energy-and-high-performance-code-action-committee-sehpcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change is administrative/procedural in nature and, therefore, does not affect the cost of construction.
GG5-19

IGCC®: SECTION 106, 106.1

Proponent: David Collins, representing SEHPCAC (SEHPCAC@iccsafe.org)

2018 International Green Construction Code

SECTION 106
PERMITS

Revise as follows:

106.1 Required. Any owner or owner’s authorized agent who intends to construct, enlarge, alter, repair, move, demolish, or change the occupancy of a building or structure, or to erect, install, enlarge, alter, repair, remove, convert or replace any energy, electrical, gas, mechanical or plumbing system, the installation of which is regulated by this code, or to cause any such work to be done, shall first make application to the authority having jurisdiction and obtain the required permit under the applicable adopted code (Informative Note: e.g., International Building Code) or regulation relevant to the intended work. Separate permits shall not be issued under this code. Exemptions from permit requirements shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other applicable laws, codes or ordinances of this jurisdiction.

Reason: Jurisdictions decide for themselves what type of permits are required and this differs widely from jurisdiction to jurisdiction. There is no reason that the IgCC should be treated differently than any other code in this respect.

This proposal is submitted by the ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance the IECC, the IgCC and the energy provisions of the IRC. The SEHPCAC held 4 open meetings in 2018. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the SEHPCAC website at: https://www.iccsafe.org-tech-support/codes/code-development-process/sustainability-energy-and-high-performance-code-action-committee-sehpcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This change is administrative/procedural in nature and, therefore, does not affect the cost of construction.
IPC Code Change Proposal

The following code change proposals are labeled as Plumbing code change proposals because they are proposals for changes to sections in chapters of the International Plumbing Code that are designated as the responsibility of the IPC Development Committee (see page x of the Introductory pages of this monograph). However, the changes included in this Group B code development cycle are to sections of the code that have been prefaced with a [CE], meaning that they are the responsibility of a different IECC Code Development Committee—IECC-Commercial Committee [CE].

The committee assigned for each code change proposal is indicated in a banner statement near the beginning of the proposal.
THIS PROPOSAL WILL BE HEARD BY THE IECC RE COMMITTEE. PLEASE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

2018 International Plumbing Code

Revise as follows:

[E] 607.5 Insulation of piping. For other than Group R2, R3 and R4 occupancies that are three stories or less in height above grade plane, piping to the inlet of a water heater and piping conveying water heated by a water heater shall be insulated in accordance with Section C404.4 of the International Energy Conservation Code. For Group R2, R3 and R4 occupancies that are three stories or less in height above grade plane, piping to the inlet of a water heater and piping conveying water heated by a water heater shall be insulated in accordance with Section R403.5.3 of the International Energy Conservation Code. Pipe insulation shall be continuous except where the piping passes through a framing member.

Reason: The intent of the proposal is to have consistency where the code requires insulation of water piping "to be continuous" as currently written in C404.5

Testimony:

SUBMITTAL FOR CONTINUOUS INSULATION

For the past 25 years I have been a Commissioner on the Rhode Island Building Code Standards Committee as both a member and chairman. During those years I have been the chairman or member of the Energy, Mechanical and Plumbing Subcommittees. I have been very pleased with the progress of the energy conservation in mechanical and plumbing systems especially relating to insulation of piping. The ICC has clearly recognized the importance of pipe insulation used for hot water conveyance. Over the years ICC has established requirements of insulation of piping and how to install the insulation to achieve maximum energy savings. Specifically, the requirement of continuous insulation through the hangers/supports as addressed in section C404.4 of the IECC. Upon discussions established by Craig DiPetrillo in regards to his findings of inconsistency, and during my research I have noticed that the IMC and IPC have not clearly delineated the continuous insulation (C404.4) requirement. I have asked Craig DiPetrillo to introduce an amendment to Section 607.5 to address this installation methodology.

Sincerely yours,

Gordon W. Preiss P. E., LEED AP
Rhode Island Building Code Standard Committee Commissioner
Westerly R. I. 02891

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The intent of the proposal is only for clarification and consistency of requirements. As such, there is no change in materials or labor to install for where the code currently requires insulation of water piping "to be continuous".
2019 GROUP B – PROPOSED CHANGES TO THE INTERNATIONAL RESIDENTIAL CODE - BUILDING

INTERNATIONAL RESIDENTIAL CODE COMMITTEE - BUILDING

The following is the tentative order in which the proposed changes to the code will be discussed at the public hearings. Proposed changes which impact the same subject have been grouped to permit consideration in consecutive changes.

Proposed change numbers that are indented are those which are being heard out of numerical order. Indentation does not necessarily indicate that one change is related to another. Proposed changes may be grouped for purposes of discussion at the hearing at the discretion of the chair. Note that some RB code change proposals may not be included on this list, as they are being heard by another committee.

2018 International Residential Code

R104.11 Alternative materials, design and methods of construction and equipment. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code. The building official shall have the authority to approve an alternative material, design or method of construction upon application of the owner or the owner’s authorized agent. The building official shall first find that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code in quality, strength, effectiveness, fire resistance, durability and safety. Compliance with the specific performance-based provisions of the International Codes shall be an alternative to the specific requirements of this code. Where the alternative material, design or method of construction is not approved, the building official shall respond in writing, stating the reasons why the alternative was not approved.

Add new text as follows:

R104.11.1 Research reports. Supporting data, where necessary to assist in the approval of materials or assemblies not specifically provided for in this code, shall consist of valid research reports from approved sources.

R104.11.1.1 Approved sources. Agencies conducting product certification or product evaluation shall be accredited by an accreditation body. The scope of accreditation shall include the acceptance criteria referenced in the research report, for the research report to be accepted for product approval.

Revise as follows:

R104.11.1 R104.11.2 Tests. Where there is insufficient evidence of compliance with the provisions of this code, or evidence that a material or method does not conform to the requirements of this code, or in order to substantiate claims for alternative materials or methods, the building official shall have the authority to require tests as evidence of compliance to be made at no expense to the jurisdiction. Test methods shall be as specified in this code or by other recognized test standards. In the absence of recognized and accepted test methods, the building official shall approve the testing procedures. Tests shall be performed by an approved agency. Reports of such tests shall be retained by the building official for the period required for retention of public records.

Add new text as follows:

R106.3.1.1 Third-party certification. Products and materials required by the code to be in compliance with a referenced standard shall be certified by a third-party certification agency as complying with the referenced standards. Products and materials shall bear the identification of the manufacturer and any markings required by the applicable referenced standards.

Add new definition as follows:

ACCREDITATION BODY. An approved, third-party organization that is independent of the grading, product certification and inspection agencies that initially accredit and subsequently monitors agencies conducting
building product certification or evaluation schemes on a continuing basis, including the competency and performance of a grading or inspection agency related to carrying out specific tasks.

**Reason:** The standard practice in building products conformity assessment involves accreditation of the agencies by an accreditation body such as ISO. Third party testing, manufacturing inspections and product certification or product evaluation provide a higher level of quality assurance on these activities for the building official. Approved sources that issue research reports must be accredited to the specific acceptance criteria referenced in the research report. This ensures that the approved sources have the requisite technical expertise and experience to conduct such activities on behalf of the building official. Harmonized language is proposed for inclusion a new Section R106.3.1.1 regarding third-party certification, and in Chapter 2 with a definition for accreditation body. A definition for Third-Party Certification Agency already exists in the IRC and remains unchanged. The language in the new Section R106.3.1.1 is identical to language in the International Plumbing Code Section 303.4. The added definition is the same as that proposed for inclusion in the International Building Code. These additions will improve the consistency and intent of the I-codes.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal coordinates the codes.
Proponent: Lee Schwartz, representing Self (lee@hbaofmichigan.com)

2018 International Residential Code

Revise as follows:

R105.2 Work exempt from permit. Exemption from permit requirements of this code shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other laws or ordinances of this jurisdiction. Permits shall not be required for the following:

**Building:**

1. One-story detached accessory structures, provided that the floor area does not exceed 200 square feet (18.58 m²).
2. Fences not over 7 feet (2134 mm) high.
3. Retaining walls that are not over 4 feet (1219 mm) in height measured from the bottom of the footing to the top of the wall, unless supporting a surcharge.
4. Water tanks supported directly upon grade if the capacity does not exceed 5,000 gallons (18,927 L) and the ratio of height to diameter or width does not exceed 2 to 1.
5. Sidewalks and driveways.
6. Painting, papering, tiling, carpeting, cabinets, counter tops and similar finish work.
7. Prefabricated swimming pools that are less than 24 inches (610 mm) deep.
8. Swings and other playground equipment.
9. Window awnings supported by an exterior wall that do not project more than 54 inches (1372 mm) from the exterior wall and do not require additional support.
10. Decks not exceeding 200 square feet (18.58 m²) in area, that are not more than 30 inches (762 mm) above grade at any point, are not attached to a dwelling and do not serve the exit door required by Section R311.4.

**Electrical:**

1. Listed cord-and-plug connected temporary decorative lighting.
2. Reinstallation of attachment plug receptacles but not the outlets therefor.
3. Replacement of branch circuit overcurrent devices of the required capacity in the same location.
4. Electrical wiring, devices, appliances, apparatus or equipment operating at less than 25 volts and not capable of supplying more than 50 watts of energy.
5. Minor repair work, including the replacement of lamps or the connection of approved portable electrical equipment to approved permanently installed receptacles.

**Gas:**

1. Portable heating, cooking or clothes drying appliances.
2. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.
3. Portable-fuel-cell appliances that are not connected to a fixed piping system and are not interconnected to a power grid.
Mechanical:

1. Portable heating appliances.
2. Portable ventilation appliances.
3. Portable cooling units.
4. Steam, hot- or chilled-water piping within any heating or cooling equipment regulated by this code.
5. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.
6. Portable evaporative coolers.
7. Self-contained refrigeration systems containing 10 pounds (4.54 kg) or less of refrigerant or that are actuated by motors of 1 horsepower (746 W) or less.
8. Portable-fuel-cell appliances that are not connected to a fixed piping system and are not interconnected to a power grid.

Plumbing:

1. The stopping of leaks in drains, water, soil, waste or vent pipe; provided, however, that if any concealed trap, drainpipe, water, soil, waste or vent pipe becomes defective and it becomes necessary to remove and replace the same with new material, such work shall be considered as new work and a permit shall be obtained and inspection made as provided in this code.
2. The clearing of stoppages or the repairing of leaks in pipes, valves or fixtures, and the removal and reinstallation of water closets, provided such repairs do not involve or require the replacement or rearrangement of valves, pipes or fixtures.

Reason: The International Residential Code contains no definition of “fence”, no listing of “fence” in the index and no sections or subsections specifically governing the material, design or method of construction for a fence. In short there are no specific code requirements for fences found in the International Residential Code. This leaves permit applicants to searching in vain through the entire IRC to find requirements for the construction of a fence when none exist. It also places inspectors in the unenivable position of having to inspect fences for which a permit was pulled without any criteria for approving the fence construction. How can a building official write a violation notice when there are no pertinent requirements to base the notice on?

While the IRC does contain an exemption for fences not over 7 feet high. This is an arbitrary number chosen for convenience and without any data to back it up. Is a fence that is 7 feet two inches inherently more dangerous to the public health, safety and general welfare than a fence that is 6 feet 11 1/2 inches?

The purpose of the code is to establish minimum requirements to safeguard the public safety, health and general welfare. Mandating the issuance of a construction permit for fences when no minimum requirements are specifically present in the code book does not safeguard the public safety, health and general welfare.

Requiring a permit for a fence, even with the under seven feet exeption, simply because the code states you must have a permit aqnd without any standards is exactly the type of overreach which leads to people not pulling permits on other, more critical, construction.

In most jurisdictions, requirements for fences have been treated as a zoning issue with zoning ordinances controlling the size, type, materials and manner of construction for a fence. The requirement for a fence permit should be totally removed from the IRC and left to local zoning.

Cost Impact: The code change proposal will decrease the cost of construction
by eliminating an unnecessary permit and the fee for that permit.
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Residential Code

Revise as follows:

[RB] APPROVED AGENCY. An established and recognized agency that is regularly engaged in conducting tests, furnishing inspection services or furnishing product certification, and has been approved by the building official. For the definition applicable in Chapter 11, see Section N1101.6.

Reason: This change removes the language that sends the user to chapter 11 and section 1101.6 of the document to find the definition of Approved Agency because, Section N1101.6 does not include the definition of Approved Agency. Also there is no need to add or repeat the definition in chapter 11 of the IRC as long as it is defined in Chapter 2 of the same IRC. This will save on printing costs as well as save energy.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The code change proposal will not increase the cost of construction.
2018 International Residential Code

Revise as follows:

[RB] BUILDING. Any one- or two-family dwelling or portion thereof, including townhouses, structure used or intended to be used for human habitation, for living, sleeping, cooking or eating purposes, or any combination thereof, or any accessory structure. For the definition applicable in Chapter 11, see Section N1101.6, for supporting or sheltering any use or occupancy, including any mechanical HVAC systems, service water heating systems and electric power and lighting systems located on the building site and supporting the building.

Reason: The definition provided for “Building” is currently the definition used for “Dwelling” and “Dwelling Unit” in the IRC. The proposed language is the same used in the IRC Chapter 11 definitions and in the IECC Residential and Commercial codes IECC Energy Code definitions, and is in line with other ICC code documents including the IMC and IFGC. It is important to maintain a consistent definition of “Building” throughout the codes. There is no need to repeat the definition in the IRC, Chapter 11 since Chapter 2 definitions apply to the entire IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There will be no cost impact with this change.
**2018 International Residential Code**

Add new definition as follows:

**BUILDING DESIGNER.** The owner of the building or the person that contracts with the owner for the design of the building structural system or who is responsible for the preparation of the construction documents. Where required by the statutes of the jurisdiction in which the project is to be constructed, the building designer shall be a registered design professional.

**Reason:** The title "building designer" is currently used twice within the IRC, in Section R502.11.4 and Section R802.10.1. In each of the two sections, "building designer" refers to a person who is qualified and responsible for designing the size, connections, and anchorage of the permanent continuous lateral bracing. Therefore, a definition of the title providing the qualifications of the individual is necessary.

Furthermore, nearly every State allows for individuals other than "registered design professionals" to prepare construction drawings for those buildings covered under the scope of the IRC. Therefore, it is essential to the correct interpretation of the code that the title "building designer" is clarified by definition to avoid potential confusion and misinterpretation of the actual qualifications and prerequisites required of those individuals given the responsibility to design one- and two-family dwellings and townhouses.

Standard ANSI/TPI 1 includes a definition of "building designer" and this proposal largely mirrors the ANSI/TPI 1 definition with a small deviation to remain consistent with verbiage in Section R106.1.

Standard ANSI/TPI 1 is a nationally developed consensus standard referenced by the IRC. Therefore, it makes logical sense to include the currently accepted definition of "building designer" for clarity, for consistency, and to avoid referencing two separate documents for the same information.

**References:**

"ANSI/TPI 1, 2.2 Definitions:

**Building Designer:** The owner of the building or the Person that contracts with the Owner for the design of the Building Structural System and/or who is responsible for the preparation of the Construction Documents. When mandated by the Legal Requirements, the Building Designer shall be a Registered Design Professional."

"Section R106.1 Submittal Documents

...The construction documents shall be prepared by a registered design professional where required by the statutes of the jurisdiction in which the project is to be constructed..."

"R502.11.4 Truss design drawings.

11. Maximum axial compression forces in the truss members to enable the building designer to design the size, connections and anchorage of the permanent continuous lateral bracing. Forces shall be shown on the truss drawing or on supplemental documents."
"R802.10.1 Truss design drawings.

11. Maximum axial compression forces in the truss members to enable the **building designer** to design the size, connections and anchorage of the permanent continuous lateral bracing. Forces shall be shown on the truss design drawing or on supplemental documents."

**Bibliography:** ANSI/TPI 1 - 2014, August 27, 2014, Truss Plate Institute, Alexandria, VA

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal does not change the current practice of building design, or who is qualified to perform the task.

Proposal # 5223
2018 International Residential Code

Revise as follows:

**[RB] BUILDING CODE OFFICIAL.** The officer or other designated authority charged with the administration and enforcement of this code, or a duly authorized representative. For the definition applicable in Chapter 11, see Section N1101.6.

**Reason:** Using the term “Building Official”, implies the code official is responsible for enforcement of only the building, does not include the building site, associated systems, and equipment. The term “Code Official” used in the IMC, IFGC, IECC Residential and Commercial codes, rather than “Building Official”; will create greater consistency with the IRC. *This will also remove the language that sends one to chapter 11 and section N1101.6.*

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

No Cost will be added with this change
RB7-19
IRC®: [RB] 202

Proponent: Lucas Pump, representing Self (l.pump@cedar-rapids.org)

2018 International Residential Code

Revise as follows:

[RB] CRAWL SPACE. An unfinished underfloor space that is not a basement.

Reason: The current definition for "crawl space" is too broad. According the current definition, I could walk into the main level of a 2-story house, and stand in the living room, and I could call that area a "crawl space". I would be under the floor of the second floor, and not in a basement, but I believe that we could all agree that this 1st floor is not a "crawl space". So, adding this additional language helps define the space better.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is just clarification of the definition, and should not have a cost impact.
RB8-19
IRC®: [RB] 202 (New); IEBC®: 202

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsea.org)

2018 International Residential Code
Revise as follows:

[RB] EMERGENCY ESCAPE AND RESCUE OPENING. An operable exterior window, door or other similar device that provides for a means of escape and access for rescue in the event of an emergency. (See also “Grade floor opening.”)

2018 International Existing Building Code
Add new definition as follows:

EMERGENCY ESCAPE AND RESCUE OPENING. An operable exterior window, door or other similar device that provides for a means of escape and access for rescue in the event of an emergency.

Reason: The intent of this proposal is to coordinate the definitions for emergency escape and rescue openings between IBC, IRC, IEBC, IPMC, IFC. This change was approved as part of Group A for IBC, IFC, IPMC as G5-18 Part 1 and 2(AS/AM).

This is a series of proposals to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated below. Other related changes will refer back to the definition for this information.

This is what the EERO requirements would look like if all of the proposals are approved.

SECTION R310

EMERGENCY ESCAPE AND RESCUE OPENINGS

R310.1 General. Emergency escape and rescue openings shall comply with the requirements of this section.

R310.2 Where required. Basements, habitable attics and every sleeping rooms shall have no fewer than one emergency escape and rescue opening in accordance with this section. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room, but shall not be required in adjoining areas of the basement. Such openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions:

1. Basements with a ceiling height of less than 80 inches (2032 mm) shall not be required to have emergency escape and rescue openings.

2. Emergency escape and rescue openings are not required from basements or sleeping rooms that have an
exit door or exit access door that opens directly into a public way or to a yard, court or exterior egress balcony that opens to a public way.

3. Basements used only to house mechanical equipment and not exceeding a total floor area of 200 square feet (18.58 m²) shall not be required to have emergency escape and rescue openings.

4. Storm shelters are not required to comply with this section where the shelter is constructed in accordance with ICC 500.

5. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:

5.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.

5.2. Two means of egress complying with Section R311.

R310.2.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Window opening control devices and fall prevention devices complying with ASTM F2090 shall be permitted for use on windows serving as a required emergency escape and rescue opening.

R310.3 Emergency escape and rescue openings. Emergency escape and rescue openings shall have minimum dimensions in accordance with Section R310.3.1 through R310.3.3.

R310.3.1 Minimum size. Emergency and escape rescue openings shall have a net clear opening of not less than 5.7 square feet (0.530 m²).

Exception: The minimum net clear opening for grade-floor emergency escape and rescue openings shall be 5 square feet (0.465 m²).

R310.3.2 Minimum dimensions. The minimum net clear opening height dimension shall be 24 inches (610 mm). The minimum net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

R310.3.3 Maximum height from floor. Emergency escape and rescue openings shall have the bottom of the clear opening not greater than 44 inches (1118 mm) above the floor.

R310.4 Emergency escape and rescue doors. Where a door is provided as the required emergency escape and rescue opening, it shall be a swinging door or a sliding door.

R310.5 Area wells. An emergency escape and rescue opening with the bottom of the clear opening below the adjacent grade shall be provided with an area well in accordance with Sections R310.5.1 through R310.5.4.

R310.5.1 Minimum size. The horizontal area of the area well shall be not less than 9 square feet (0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area well shall allow the emergency escape and rescue opening to be fully opened.

Exception: The ladder or steps required by Section R310.5.2.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the area well.
**R310.5.2 Ladder and steps.** Area wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a an approved permanently affixed ladder or steps. The ladder or steps shall not be obstructed by the emergency escape and rescue opening when the window or door is in the open position. Ladders or steps required by this section shall not be required to comply with Section R311.7.

**R310.5.2.1 Ladders.** Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center (o.c.) vertically for the full height of the area well.

**R310.5.2.2 Steps.** Steps shall have an inside width of at least 12 inches (305 mm), shall have minimum treads depth of 5 inches (127 mm) and a maximum riser height of 18 inches (457 mm) for the full height of the area well.

**R310.5.3 Drainage.** Area wells shall be designed for proper drainage by connecting to the building’s foundation drainage system required by Section R405.1.

*Exception:* A drainage system for area wells is not required where the foundation is on well-drained soil or sand gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

**R310.5.4 Bars, grilles, covers and screens.** Where bars, grilles, covers, screens or similar devices are placed over emergency escape and rescue openings, bulkhead enclosures, or area wells that serve such openings, the minimum net clear opening size shall comply with Sections R310.2 through R310.2.2 and R310.4.1. Such devices shall be releasable or removable from the inside without the use of a key or tool or force greater than that required for the normal operation of the escape and rescue opening.

**R310.6 Emergency escape and rescue openings under decks and porches.** Emergency escape and rescue openings installed under decks and porches shall be fully operable and provide a path not less than 36 inches (914 mm) in height to a yard or court.

**R310.7 Replacement windows for emergency escape and rescue openings.** Replacement windows installed in buildings meeting the scope of this code shall be exempt from Section R310.2 and R310.4, provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer's largest standard size window that will fit within the existing frame or existing rough opening. The replacement window is of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

2. Where the replacement window is not part of a change of occupancy.

**R310.8 Dwelling additions.** Where *dwelling additions* contain sleeping rooms, an emergency escape and rescue opening shall be provided in each new sleeping room. Where *dwelling additions* have *basements*, an emergency escape and rescue opening shall be provided in the new *basement*.

*Exceptions:*

1. An emergency escape and rescue opening is not required in a new *basement* that contains a sleeping room with an emergency escape and rescue opening.

2. An emergency escape and rescue opening is not required in a new *basement* where there is an emergency escape and rescue opening in an existing *basement* that is *accessed* from the new *basement*.
3. An operable window complying with Section 310.9.1 shall be acceptable as an emergency escape and rescue opening.

**R310.9 Alterations or repairs of existing basements.** New sleeping rooms created in an existing *basement* shall be provided with emergency escape and rescue openings in accordance with Section R310.1. Other than new sleeping rooms, where existing *basements* undergo alterations or repairs an emergency escape and rescue opening is not required.

**Exception:** An operable window complying with Section 310.9.1 shall be acceptable as an emergency escape and rescue opening.

**R310.9.1 Existing Emergency escape and rescue openings.** Where a change of occupancy would require emergency escape and rescue opening in accordance with Section R310.1, operable windows serving as the emergency escape and rescue opening shall comply with the following:

1. An existing operable window shall provide a minimum net clear opening of 4 square feet (0.38 m²) with a minimum net clear opening height of 22 inches (559 mm) and a minimum net clear opening width of 20 inches (508 mm).

2. A replacement window where such window complies with both of the following:

   2.1 The replacement window meets the size requirements in Item 1.

   2.2 The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This proposal is editorial.

Proposal # 4141

RB8-19
2018 International Residential Code

Revise as follows:

[R] FIRE-RETARDANT-TREATED WOOD. Pressure-treated lumber and plywood that, when impregnated with chemicals by a pressure process or other means during manufacture, exhibit reduced surface burning characteristics and resist propagation of fire.

Reason: The definition of fire retardant treated wood is being copied from the IBC, for consistency within ICC codes. Also, the existing definition states that fire retardant treated wood (FRTW) is pressure treated but the sub definitions (and the section on FRTW in chapter 8) point out that it can be made by pressure treatment or other means during manufacture. The sub definitions of "other means during manufacture" and "pressure process" are being slightly revised for two reasons: to clarify that impregnation with a fire retardant formulation is the essential issue and to make them parallel to each other.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This corrects the definition and makes it consistent with the IBC.
2018 International Residential Code

Revise as follows:

[RB] FIRE SEPARATION DISTANCE. The distance measured from the building face to one of the following:

1. To the closest interior lot line.
2. To the centerline of a street, an alley or public way.
3. To an imaginary line between two buildings on the lot.

The distance shall be measured at a right angle from the face of the wall.

Reason: The definition for fire separation distance is identical to that in the IBC. Unlike the IBC, the IRC does not have a requirement to use an “imaginary line” for fire separation distance assessment. It’s retention in the definition creates confusion and should therefore be eliminated.

Cost Impact: The code change proposal will decrease the cost of construction. Elimination of unnecessary and confusing language may result in cost reductions where the imaginary line was erroneously applied.
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials
(don.sivigny@state.mn.us)

2018 International Residential Code

Add new definition as follows:

[RB] Flashing. A non-corrosive, water-resistant material, installed to resist water entry, and direct water away from or out of the building assembly.

Reason: There is a need to prevent water from seeping in and causing damage to the home's walls, ceilings and other assemblies. This water is causing structural damage to the home, or creating moisture and mold problems throughout the home. This form of protection is a necessary construction practice, and it's widely applied to commercial, residential and industrial structures within the industry. Therefore, there is a need to define flashing.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

There is no Cost Impact with this Change

Proposal # 5386
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials
(don.sivigny@state.mn.us)

2018 International Residential Code
Add new definition as follows:

[RB] FLOOR AREA. The calculated square footage of the floor within the inside perimeter of the exterior walls of the building under construction, without deduction for hallways, stairways, closets, the thickness of interior walls, columns or other features.

Reason: The definition for “floor area” is added because that term is not defined by the 2018 IRC and it is necessary to establish uniform application of the Building Code. The proposed definition of “floor area” will be consistent with the definition of “floor area” as used in the 2018 IBC. It is therefore reasonable to add the definition of “floor area” to the proposed code to encourage uniform enforcement of the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There is no Cost Impact with this change
**2018 International Residential Code**

**Proponent:** Donald Sivigny, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

Revise as follows:

**[RB] GRADE FLOOR OPENING.** A window or other opening located such that the sill height bottom of the clear opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening. (See also “Emergency escape and rescue opening.”)

**Reason:** The rationale for the code change stems from the inconsistent interpretation of the word “sill” in the industry, and also to give a clearer more uniform benchmark for where the height requirements in Sections R310 and R312 are measured to

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase the cost of construction as it is simply creating a clearer definition of what the terminology “Grade Floor Opening” means. In fact it may decrease cost of construction from delays that are created when a code correction is written that slows down or stops construction. Time is money on a jobsite, and the delay of one day typically changes the construction Schedule which costs the builder Money.
RB14-19
IRC®: [RB] 202 (New)

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccunsafe.org)

2018 International Residential Code
Revise as follows:

[RB] GRADE FLOOR EMERGENCY ESCAPE AND RESCUE OPENING. A window or other emergency and escape and rescue opening located such that the sill-height of the bottom of the clear opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening. (See also “Emergency escape and rescue opening.”)

Reason: This definition is used only in Section IRC R310.2.1. The change to the definition is so is matches how it will be used in the technical criteria. What is a ‘sill’ is not clear – the modification is for consistency with technical criteria. It is important to indicate that this is to the bottom of the opening (otherwise a below grade window could be very deep). See also revisions to IRC R310.2.1. There was a similar proposal approved for Group A for IBC - G4-18(AS).

This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a coordination item for requirements for EEROs already permitted between the codes.

Proposal # 4142

RB14-19
2018 International Residential Code

Revise as follows:

[RB] INSULATING SHEATHING. An insulating board A rigid panel or board insulation material having a thermal resistance of not less than R-2 of the core material with properties suitable for use on walls, floors, roofs, or foundations.

For the definition applicable in Chapter 11, see Section N1101.6.

Reason: This change simply applies to the definition of insulating sheathing. The recent IBC G proposal G6 accepted as submitted the IBC definition, with the revised wording proposed here and consistency within ICC definitions is important.

Proposed definition will read:

A rigid panel or board insulation material having a thermal resistance of not less than R-2 of the core material with properties suitable for use on walls, floors, roofs, or foundations.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Change in definition only.

Proposal # 5786
2018 International Residential Code

SECTION R202
DEFINITIONS

Revise as follows:

[RB] INSULATING SHEATHING. An insulating board having a thermal resistance of not less than R-2 of the core material with properties suitable for use on walls, floors, roofs, or foundations.

Reason: This proposal for the IRC coordinates with G6-18 approved “As Submitted” during the 2018 ICC code development cycle for the 2021 IBC. This proposes the same definition for Insulating Sheathing for the IRC. Within the IRC, the term “insulating sheathing” is only in Chapter 7.

The proposal improves the definition to better fit context of use of this term and material in the IRC (and IBC). For example, the term "rigid panel" is added to recognize composite assemblies that are not homogenous. The clarification of use in walls, floors, roofs, and foundations reflects common use of foam plastic insulating sheathing materials.

Although the first printing of the IRC had this term in Chapter 11, ICC Staff has indicated that the presence of term in Section N1106.2 and in the IEEC-RE Chapter 2 is errata. The term is not used in the code language and therefore should have been removed editorially before publication.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed definition revision adds clarity to the meaning of the code and as such, is only editorial in nature.
Proponent: Samuel Steele, representing Seattle Department of Construction and Inspection (SDCI) 
(samuel.steele@seattle.gov)

2018 International Residential Code
Revise as follows:

[RB] LOT. A measured portion or parcel of land considered as a unit having fixed boundaries.

[RB] LOT LINE. A line dividing one lot from another, or from a street or any public place. The line that bounds a plot of ground described as a lot in the title to the property.

Reason: The current definitions lack information on what distinguishes a lot or parcel as a unit. A lot or parcel must be measured, have fixed boundaries, and be tied to the title of the property. Code enforcement officials work with these definitions on every project. Therefore, the definition of them needs to be clear and consistent for identifying lots and parcels of land.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is simply a clarification of current definitions to assist with enforcement in the field. It will not have a cost impact.

Proposal # 4345

RB17-19
2018 International Residential Code

[RB] NONCOMBUSTIBLE MATERIAL. Material that passes the test procedure for defining noncombustibility of elementary requirements for noncombustible materials set forth in ASTM E136.

Reason: This proposal simply addresses the definition of noncombustible materials. The recent set of proposals in the IBC (FS2 and FS3) made it clear that ASTM E136 (and the code) applies to materials that are noncombustible materials and are not elementary materials (since elementary materials are only those contained in the periodic table of elements). For example, neither steel nor cement are elementary materials but they are noncombustible materials. Thus, any material that passes the criteria set forth in ASTM E136 is considered a noncombustible material. ASTM E136 does not apply to laminated or coated materials.

The proposed definition will read:

[RB] NONCOMBUSTIBLE MATERIAL. Material that passes the requirements for noncombustible materials set forth in ASTM E136.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This simply changes an incorrect definition.
2018 International Residential Code

Revise as follows:

Reason: The current definition is incorrect in two ways:
- The term "elementary materials" is misused here and was removed from ASTM E136 in 1973, and from the IBC during the 2018 Group A revision process.
- There is no "test procedure for defining noncombustibility" in E136. Materials are simply reported as having passed E136. It is the codes which declare materials that pass E136 to be noncombustible.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change simply corrects a definition which contains some technical flaws, so it will have no affect on construction costs.
2018 International Residential Code
Add new definition as follows:

PORCH. An open, screened, or glazed, one story portion of a building that is separated by a thermal envelope, and has a space conditioning system exceeding 3.4 Btus or 1 watt of energy use at peak operation, or that is capable of being shut off without shutting off the space conditioning system to other areas of the building.

Reason: There is no industry standard language as to what a porch is defined as. Many times a deck becomes a porch and then actually becomes conditioned space. The code does define decks and conditioned spaces but not a porch. Therefore, there is a need for a definition of what a porch actually is. This language is very similar to the same language used to define a sunroom, in the code with some modifications.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase the cost of construction and may actually decrease the costs because it creates a consistent definition of what a porch is, no longer do the code official and builder need to guess how it is going to be permitted, defined and built or what are the code requirements that need to be met.
2018 International Residential Code

[RB] ROOF ASSEMBLY. A system designed to provide weather protection and resistance to design loads. The system consists of a roof covering and roof deck or a single component serving as both the roof covering and the roof deck. A roof assembly includes the roof deck, underlayment and roof covering, and can also include an underlayment, thermal barrier, ignition barrier, insulation or a vapor retarder. For the definition applicable in Chapter 11, see Section N1101.6.

Reason: This proposal simply revises the definition of roof assembly. The recent action on WUI proposal WUIC 1 added into the IWUIC a definition based on the IBC definition of roof assembly and it is being proposed here as a revision, for consistency among ICC definitions. Furthermore this definition is more accurate since not all roof assemblies will include an underlayment and the sentence already states that it does include a roof deck and, therefore, stating that it "can include a roof deck" is not correct.

The proposed definition reads as follows:

[RB] ROOF ASSEMBLY. A system designed to provide weather protection and resistance to design loads. The system consists of a roof covering and roof deck or a single component serving as both the roof covering and the roof deck. A roof assembly includes the roof deck, underlayment and roof covering, and can also include an underlayment, thermal barrier, ignition barrier, insulation or a vapor retarder. For the definition applicable in Chapter 11, see Section N1101.6.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Definition change only.
Proponent: David Renn, PE, SE, City and County of Denver, representing Code Change Committee of Colorado Chapter of ICC (david.renn@denvergov.org)

2018 International Residential Code

Revise as follows:

[RB] TOWNHOUSE. A single-family dwelling unit constructed in a group of three or more attached units in which each unit extends from foundation to roof and has a yard or public way on not less than two sides that extends at least 50 percent of the length of each of these two sides.

Reason: The definition of "townhouse" requires a yard or public way on not less than two sides, which is intended to provide some degree of independence from the other townhouse units in a building; however, the definition does not dictate the length required for the yard or public way. This proposal requires a minimum of 50% of the length of a side to have a yard or public way, which is a reasonable amount to provide the degree of independence intended and to provide fire department access. There is a need for this requirement as configurations of townhouses can create situations with a side that has a relatively small proportion of the wall length that has a yard or public way; for example, townhouses that are configured around the corner of a townhouse building per the drawing below.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal provides a clarification to the current code requirements so it should not increase or decrease the cost of construction.
Proponent: Craig Conner, representing self (craig.conner@mac.com); Joseph Lstiburek, representing self (joe@buildingscience.com)

2018 International Residential Code

Revise as follows:

[RB] VAPOR DIFFUSION PORT. A passageway for conveying An assembly constructed or installed within a roof assembly at an opening in the roof deck to convey water vapor from an unvented attic to the outside atmosphere.

Reason: Objective: Provide consistency with IBC and improve clarity
This code change provides consistency with the IBC and improves clarity.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This provides consistency with the IBC and provides an improved definition. It does not change costs.
2018 International Residential Code

Revise as follows:

[RB] VAPOR PERMEABLE. The property of having a moisture vapor permeance rating of 5 perms (2.9 × 10⁻¹⁰ kg/Pa • s • m²) or greater, where tested in accordance with the desiccant method using Procedure A or Procedure B of ASTM E96. A vapor permeable material permits the passage of moisture vapor.

Reason: Objective: Define vapor permeable as 5 perms or greater using Procedure A or B
Action: Amend IRC in Cycle B with same language submitter in Cycle A for IBC

Relying on only Procedure A is inaccurate and misleading. The existing code language limits the use of newer materials and systems such as "smart" materials that can be "tuned" to address moisture control issues in different climate zones. The existing definition applied to asphalt felts and Type D coated papers and dates back over a half a century. For Type D papers the original Federal Specification UUP-147 was issued in 1948. The technical rationale for this change can be found in the following link:

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This adds a test procedure that is more appropriate for some products.
**2018 International Residential Code**

Add new definition as follows:

**WATERPROOFING.** Treatment of a surface or structure that bridges nonstructural cracks, and is designed to resist the passage of water under hydrostatic pressure or through capillary action, which may penetrate the building assembly.

**Reason:** Damproofing in Section R406.1 is no longer commonly used in the code knowledgeable industry, as it is not an effective way to keep the buildings below grade foundation system, dry, durable and free from moisture and mold issues affecting homes and homeowners today. The typical damproofing, system will require additional steps such as parging, or other materials be applied to the foundation wall prior to the application of the damproofing product. This adds additional costs in materials and labor for the builder. This cost is passed along to the consumer. Knowledgeable builders of today understand the benefits of waterproofing and the overall cost savings in initial costs, and the reduction in costs associated with call backs and repairs of wet foundation systems. Therefore it is necessary to define waterproofing

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase the cost of construction as it is simply correcting the definition for clarity reasons. In fact this clarity may even reduce the costs of the code from delays that happen when code corrections are written for a specific job or building by more clearly defining what the code means by, Waterproofing. These delays caused by code corrections costs the builders money.
202 Definitions. Window Clear Opening Height: The lowest part of the window opening of an operable window measured from the interior floor below.

WINDOW CLEAR OPENING HEIGHT. The lowest part of the window opening of an operable window measured from the interior floor below.

Reason: There is a need to define what window clear opening height is and where it is measured as referenced in the IRC Sections on Emergency Escape and Rescue and Window Fall Protection. This definition is necessary to clarify confusion about where the sill height is measured. The incorporation of this definition into the code is necessary to provide uniformity of construction, inspection and enforcement of the requirements within the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase the cost of construction as it is simply correcting the definition for clarity reasons. In fact, this clarity may even reduce the costs of the code from delays that happen when code corrections are written for a specific job or building by more clearly defining what the code means by Window Clear Opening. These delays caused by code corrections costs the builders money.
2018 International Residential Code

Add new definition as follows:

**POST FRAME BUILDING SYSTEM.** A building system characterized by primary structural frames of wood posts as columns to support floors and trusses or rafters as roof framing. Roof framing is attached to the posts, either directly or indirectly through girders. Posts are embedded in the soil and supported on isolated footings, or are attached to the top of piers, concrete or masonry walls, or slabs-on-grade. Secondary framing members, purlins in the roof and girts in the walls, are attached to the primary members to provide lateral support and to transfer sheathing loads, both in-plane and out-of-plane, to the posts and roof framing.

R301.1.1 Alternative provisions. As an alternative to the requirements in Section R301.1, the following standards are permitted subject to the limitations of this code and the limitations therein. Where engineered design is used in conjunction with these standards, the design shall comply with the International Building Code.

1. AWC Wood Frame Construction Manual (WFCM).
2. AISI Standard for Cold-Formed Steel Framing—Prescriptive Method for One- and Two-Family Dwellings (AISI S230).

Add new standard(s) as follows:

**ASABE**

American Society of Agricultural and Biological Engineers
2950 Niles Road
St. Joseph MI 49085
US

**ASABE**

American Society of Agricultural and Biological Engineers
2950 Niles Road
St. Joseph MI 49085
US

**EP 484.3 MON2016:: Daiphragm Design of Metal-clad, Wood-frame Rectangular Buildings..........R301.1.1**

Revise as follows:
EP 486.2 OCT 2012: Shallow-post and Pier Foundation Design.........R301.1.1

ASABE

EP 559.2 MON 2016: Design Requirements and Bending Properties for Mechanically Laminated Wood Assemblies.............R301.1.1

Reason: Post frame design and construction has been recognized in the IBC and IRC as a popular building construction option for many years. The material and labor advantages are more often now being recognized in residential construction. Post frame is an engineered construction method that often requires significant design in the areas of isolated foundations; nail lamination of wood elements to create columns and headers; and diaphragm design for the transfer wind load throughout the structure. This definition specifically identifies to the reader that there are code recognized standards to be followed to ensure proper design.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Addition of this definition will not change the requirements of the code but will further educate the code user.

Add new definition as follows:

**[RB] 3D PRINTED BUILDING CONSTRUCTION.** A process for fabricating buildings and structures from 3D model data using automated equipment that deposits construction material in a layer upon layer fashion.

Revise as follows:

**R301.1.1 Alternative provisions.** As an alternative to the requirements in Section R301.1, the following standards are permitted subject to the limitations of this code and the limitations therein. Where engineered design is used in conjunction with these standards, the design shall comply with the International Building Code.

1. **AWC Wood Frame Construction Manual (WFCM).**
2. **AISI Standard for Cold-Formed Steel Framing—Prescriptive Method for One- and Two-Family Dwellings (AISI S230).**
3. **ICC Standard on the Design and Construction of Log Structures (ICC 400).**
4. **UL 3401 Outline of Investigation for 3D Printed Building Construction.**

Add new standard(s) as follows:

**UL 3401 -19: Outline of Investigation for 3D Printed Building Construction**

**Reason:** 3D building construction has moved from a conceptual stage to reality, and projects are being proposed in an increasing number of jurisdictions. Unfortunately the prescriptive design and construction requirements in the IRC are not applicable to 3D printed fabrication techniques, so code officials have to approve this construction based on limited equivalency evaluations that may not take into account variations in material properties introduced by the 3D printing process, or variances in the physical characteristics of the construction materials used.

The UL 3401 Outline of Investigation for 3D Printed Building Construction was developed to evaluate critical aspects of this construction process, and level the playing field so that 3D printed building techniques comply with an equivalent level of safety and performance as legacy construction techniques currently in the code.

This proposal introduces a definition for 3D Printed Building Construction and revises the alternate design methods in R301.1.1 to permit UL 3401 to be used to evaluate this construction. Note that a companion proposal introduces an Annex U covering this in more detail, which may be adopted by jurisdictions to use. These two proposals will work together, but each also stands on its own.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is a new construction technique that simply provides an alternative to traditional construction methods and may possibly reduce the cost of construction.
Staff Analysis: A review of the standard proposed for inclusion in the code, UL 3401, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Residential Code

Revise as follows:

**R301.1.3 Engineered design.** Where a building of otherwise conventional construction contains structural elements exceeding the limits of Section R301 or otherwise not conforming to this code, these elements shall be designed in accordance with accepted engineering practice. The extent of such design need only demonstrate compliance of nonconventional elements with other applicable provisions and shall be compatible with the performance of the conventional framed system. The owner or owner's authorized agent shall confirm that the design is performed to the extent necessary to comply with the provisions of Section R301.1. Engineered design in accordance with the International Building Code is permitted for buildings and structures, and parts thereof, included in the scope of this code.

**Reason:** The IRC allows for specific, selected portions of a structure to be designed per the requirements of the IBC or other accepted standard, while the remaining portion of the structure remains governed by the prescriptive design methods contained in the IRC. When providing such an engineered design for a selected element in a system, it should be noted that the design of additional elements, outside the original specific scope, may be required in order to insure a continuous load path as directed by Section R301.1.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The modified language is intended to clarify the requirements of engineered designs which fall outside the conditional limits of the IRC.
2018 International Residential Code

Revise as follows:

SECTION R202
DEFINITIONS

Add new text as follows:

INTERMODAL SHIPPING CONTAINER. A six-sided steel unit originally constructed as a general cargo container used for the transport of goods and materials.

R301.1.4 Intermodal shipping containers. Intermodal shipping containers shall be designed in accordance with the structural provisions in Section 3114 of the International Building Code.

Reason: This code change purpose is to introduce intermodal shipping containers into the International Residential Code based on requests by code officials in the U.S. Prior to this proposal, several jurisdictions had created their own individual regulations or ordinances, or had administered additional requirements beyond the code (e.g. Section R104.11 “Alternative Materials, design and methods of construction and equipment”) so at to be comfortable to ensure a safe structure. This code change proposal is in response to those requests to develop a provision in order to establish a consistent set of provisions which cover the minimum safety requirements, but which do not duplicate existing code provisions.

The proposed definition is consistent with the successful code change proposal to the International Building Code, new Section 3114. For consistency, we are introducing that same definition here.

The reference to the International Building Code has been modeled after Sections R301.1.1 through R301.1.3. The BCAC Shipping Container Working Group chose not to duplicate the newly accepted shipping container structural design language in the International Building Code. This proposal is making a simple reference the new section in the IBC where the provisions for shipping container structural safety are contained. As Section R301.1 applies to structural design only, the other non-structural provisions of the International Residential Code would apply as required (e.g. energy, plumbing, mechanical, electrical, etc.). Also, because Section R301.1.1 deals with primarily alternative sources of structural design (e.g. independent reference standard structural design resources outside the codes), the BCAC shipping container Working Group determined it to be more appropriate to separate this reference to the IBC for clarity.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes.

Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/building-code-action-committee-bcac/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The code change proposal will decrease the cost of construction. This new code section will provide clarity on how to consistently design with, permit, and field inspect shipping containers that are repurposed for residential
building construction. Current use of repurposed intermodal shipping containers requires the owner or builder to submit through the alternative means and methods administrative provisions.

Proposal # 4133

RB30-19
Proponent: Kelly Cobeen, Wiss Janney Elstner Associates, representing Federal Emergency Management Agency and Applied Technology Council Seismic Code Support Committee (FEMA/ATC SCSC) (KCobeen@wje.com); Michael Mahoney, representing Federal Emergency Management Agency (mike.mahoney@fema.dhs.gov)

2018 International Residential Code

Revise as follows:
FIGURE R301.2(2) - continued
SEISMIC DESIGN CATEGORIES
**FIGURE R301.2(3) - continued**

**ALTERNATE SEISMIC CATEGORIES**

**Reason:** This proposal adds new maps addressing Seismic Design Categories for Guam, the Northern Mariana Islands, and American Samoa. This new information is provided in two new figures added to the existing map sets, one added to Figure R301.2(2) Seismic Design Category map set, and one to the Figure R301.2(3) Alternate Seismic Design Category map set. This change will make Seismic Design Category information more readily available and will make the geographic areas addressed by seismic hazard maps consistent between the IRC and the IBC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There is no cost impact.
RB32-19
IRC®: FIGURE R301.2(5)B

Proponent: T. Eric Stafford, representing Insurance Institute for Business and Home Safety (testafford@charter.net)

2018 International Residential Code
Revise as follows:
**FIGURE R301.2(5)B**

**REGIONS WHERE WIND DESIGN IS REQUIRED**

**Reason:** This proposal corrects an error in the 2015 and 2018 IRC that became evident as result of the 2017 hurricanes that impacted the Caribbean and Southern United States. Puerto, Rico, Guam, Virgin Island, American Samoa, and Hawaii have been considered areas requiring wind design since the first edition of the IRC. When the Wind Design Required was introduced to the 2012 IRC, a note was provided on the figure indicating that Puerto Rico, Guam, Virgin Islands, American Samoa and Hawaii were other regions requiring wind design. The wind speed map and the wind design required map in the 2015 IRC were updated for consistency with ASCE 7-10. However, the note regarding Puerto Rico, Guam, Virgin Islands, American Samoa and Hawaii included on the 2012 wind design required map was inadvertently not included. The proposal simply restores that note.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Will not impact cost as these locations have historically required wind design by all versions of the IRC prior to the 2015 Edition.

Proposal # 4366

For SI: 1 pound per square foot = 0.0479 kPa, 1 mile per hour = 0.447 m/s.

- Where weathering requires a higher strength concrete or grade of masonry than necessary to satisfy the structural requirements of this code, the frost line depth strength required for weathering shall govern. The weathering column shall be filled in with the weathering index, "negligible," "moderate" or "severe" for concrete as determined from Figure R301.2.4. The grade of masonry un
- Where the frost line depth requires deeper footings than indicated in Figure R403.1(1), the frost line depth strength required for weathering shall govern. The jurisdiction shall fill in the frost line depth column with the minimum depth of footing below finish grade.
- The jurisdiction shall fill in this part of the table to indicate the need for protection depending on whether there has been a history of local subterranean termite damage.
- The jurisdiction shall fill in this part of the table with the wind speed from the basic wind speed map [Figure R301.2(5)(A)]. Wind exposure category shall be determined on a site-specific basis in accordance with Section R301.2.1.4.
c. The outdoor design dry-bulb temperature shall be selected from the columns of \( 97\% \) -percent values for winter from Appendix D of the International Plumbing Code. Deviations from the Appendix D temperatures shall be permitted to reflect local climates or local weather experience as determined by the building official. [Also see Figure R301.2(1)]

d. The jurisdiction shall fill in this part of the table with the seismic design category determined from Section R301.2.2.1.

e. The jurisdiction shall fill in this part of the table with the (a) the date of the jurisdiction’s entry into the National Flood Insurance Program (date of adoption of the first code or ordinance for management of flood hazard areas), (b) the date of the Flood Insurance Study and (c) the panel numbers and dates of the currently effective FIRM and FBFM or other flood hazard map adopted by the authority having jurisdiction, as amended.

f. In accordance with Sections R905.1.2, R905.4.3.1, R905.5.3.1, R905.6.3.1, R905.7.3.1 and R905.8.3.1, where there has been a history of local damage from the effects of ice damming, the jurisdiction shall fill in this part of the table with “YES.” Otherwise, the jurisdiction shall fill in this part of the table with “NO.”

i. The jurisdiction shall fill in this part of the table with the 100-year return period air freezing index (BF-days) from Figure R403.3(2) or from the 100-year (99 percent) value on the National Climatic Data Center data table “Air Freezing Index-USA Method (Base 32°F).”

j. The jurisdiction shall fill in this part of the table with the mean annual temperature from the National Climatic Data Center data table “Air Freezing Index-USA Method (Base 32°F).”

k. In accordance with Section R301.2.1.5, where there is local historical data documenting structural damage to buildings due to topographic wind speed-up effects, the jurisdiction shall fill in this part of the table with “YES.” Otherwise, the jurisdiction shall indicate “NO” in this part of the table.

l. In accordance with Figure R301.2(5)A, where there is local historical data documenting unusual wind conditions, the jurisdiction shall fill in this part of the table with “YES” and identify any specific requirements. Otherwise, the jurisdiction shall indicate “NO” in this part of the table.

m. In accordance with Section R301.2.1.2 the jurisdiction shall indicate the wind-borne debris wind zone(s). Otherwise, the jurisdiction shall indicate “NO” in this part of the table.

n. The jurisdiction shall fill in those sections of the table to establish the design criteria using Table 1a or 1b from ACCA Manual J or established criteria determined by the jurisdiction.

o. The jurisdiction shall fill in this section of the table using the Ground Snow Loads in Figure R301.2(6).

p. The jurisdiction shall fill in this section of the table to establish the design criteria using Table 10A from ACCA Manual J or established criteria as determined by the jurisdiction.
**Reason:** The overall change will help jurisdictions complete the manual J portion of the table and help plans examiners in completing reviews.

The upper portion of the table remains unchanged, except for the removal of the “WINTER DESIGN TEMP” column and footnote e. This currently creates a conflict within the table itself. Footnote e states the winter design temperature shall be selected from appendix D of the International Plumbing Code using the 97 ½ percent value. The Manual J portion states that the winter design come from table 1A which uses the 99 percent value. Removing the “WINTER DESIGN TEMP” column and footnote e eliminates this conflict.

The Manual J portion has been reformatted to clarify the design parameters and removed default values. We will take each cell and explain:

**Wind Velocity Heating:** Deleted from table

This value is not found in table 1A or 1B of Manual J. The default value in Manual J is 7.5mph. This is also the default value used in all Manual J software. For those who have a Manual J (version two) the explanation is on page 177 and is reprinted here for all to review:

“The default values for wind velocity are 15 MPH for heating and 7 ½ MPH for cooling. These velocities do not represent the most severe wind conditions that will be experienced when the outdoor temperature is at the winter or summer design temperature, but they do represent values that are compatible with normal weather patterns. If a location has a reputation for wind velocities that consistently exceed these defaults during non-
storm conditions, an appropriate set of velocity values may be substituted for the default values.”

**Wind Velocity Cooling:** Deleted from table See reason above

**Elevation:** Unchanged

**Altitude Correction Factor °:** Added new footnote

Provides direction to the correct table in Manual J. This is the only value in the Manual J section that does not appear in table 1A or 1B

o. The jurisdiction shall fill in this section of the table to establish the design criteria using Table 10A from ACCA Manual J or established criteria determined by the jurisdiction.

**Summer design grains:** New

This was added to help the plans examiner during plan review. This is a critical design perimeter as this the one of the values used to calculate the latent load (moisture) for cooling. This is the value that designers will change to increase (artificially) the latent load for cooling and therefore the need for larger equipment. This value is plainly seen in Manual J reports. We have provided two examples below and a portion of Manual J table 1A.

**Indoor winter design relative humidity:** Modified

Was labeled ‘Winter humidity’ and was assumed that this was indoor design relative humidity. This change makes it clear.

**Indoor winter design temperature:** Modified

Was labeled ‘Indoor design temperature’ and was assumed to be the winter design as it was under the “WINTER DESIGN TEMP°” column. With the above coulomb removed this change makes it clear the value should be the indoor winter design temperature.

**Outdoor winter design temperature:** Modified

Was labeled ‘Winter heating’ and was assumed that this was outdoor design temperature. This change makes it clear.

**Heating temperature difference:** Unchanged.

**Latitude:** Unchanged

**Daily range:** Unchanged

**Coincident wet bulb:** Unchanged

**Indoor summer design relative humidity:** Modified

Was labeled ‘Summer humidity’ and was assumed that this was the indoor design relative humidity. This change makes it clear.
Indoor summer design temperature: Modified

This was labeled as ‘Design temperature cooling’ and was assumed to be the indoor summer design temperature. This change makes it clear.

Cooling temperature difference: Unchanged

FOOTNOTES: The language of the footnotes remains unchanged. They were renumbered do to the removal of footnote e and a new footnote o.

<td>59 to 72</td>
<td>30%</td>
<td>70°</td>
<td>35°</td>
<td>35°</td>
</tr>
</tbody>
</table>
As you can see from the tables above there is a large difference in the design grains from a dry climate like Denver, Colorado and humid climate like St. Augustine, Florida. You can also see from table 1A that depending on your indoor relative humidity design the design grains change. The key for reviewers is not to get stuck on an exact number, but to know that dry climates will always have a negative number and humid climates will have a positive number.

</tr>
</tbody>
</table>
The two reports above are both for Denver, Colorado and both are correct and yet you see the Grains Difference are not the same. This value will vary slightly depending on the weather data within the software. Again, small differences will not change the calculation significantly.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The revised table will not increase the heating or cooling loads. It may help for more accurate load calculations, therefore smaller equipment and possible reduced costs.

For SI: 1 pound per square foot = 0.0479 kPa, 1 mile per hour = 0.447 m/s.

a. Where weathering requires a higher strength concrete or grade of masonry than necessary to satisfy the structural requirements of this code, the frost line depth strength required for weathering shall govern. The weathering column shall be filled in with the weathering index, “negligible,” “moderate,” or “severe” for concrete as determined from Figure R301.2(4). The grade of masonry un
b. Where the frost line depth requires deeper footings than indicated in Figure R403.1(1), the frost line depth strength required for weathering shall govern. The construction shall fill in the frost line depth column with the minimum depth of footing below finish grade.
c. The jurisdiction shall fill in this part of the table to indicate the need for protection depending on whether there has been a history of local subsurface termite damage.
d. The jurisdiction shall fill in this part of the table with the wind speed from the basic wind speed map [Figure R301.2(5)(A)]. Wind exposure category shall be determined on a site-specific basis in accordance with Section R301.2.1.4.

Reason: It is sufficient only to identify the title and date of the community’s Flood Insurance Study. Flood Insurance Studies are official reports provided by the Federal Emergency Management Agency that include or contain the Flood Insurance Rate Maps (FIRM), the Flood Boundary and Floodway Map (FBFM), the water surface elevation of the base flood and supporting technical data.

The requirement to list the panel numbers and associated dates of all currently effective FIRMs and FBFMs is burdensome, especially in large jurisdictions with multiple panels. Additionally, some states permit communities to automatically adopt updated FISs and accompanying FIRMs. Requiring individual panel numbers and dates of newly updated FIRMs would require those communities to modify the list with issuance of each new FIRM and defeats the purpose of the auto-adopt mechanism.

This proposal brings the establishment of the flood hazard area in line with Section 1612.3 of the IBC, which requires only identification of the title and date of issuance of the FIS.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

No additional cost. The proposal eliminates an administrative burden on communities.

**TABLE R301.2(2)**

**COMPONENT AND CLADDING LOADS FOR A BUILDING WITH A MEAN ROOF HEIGHT OF 30 FEET LOCATED IN EXPOSURE B (ASD) (psf)**

Note: The table provides design wind speeds for different exposure conditions and building components. The values are given in miles per hour (mph) for the ultimate design wind speed, $V_{wd}$. The table is organized by zone and effective wind areas, with columns for different wind speeds (90, 95, 100, etc.) and rows for negative (Neg) and positive (Pos) directions.

Delete and substitute as follows:
For SI: 1 foot = 304.8 mm, 1 degree = 0.0175 rad.

**Note:** a = 4 feet in all cases.

**FIGURE R301.2(8)**
COMPONENT AND CLADDING PRESSURE ZONES
For SI: 1 foot = 304.8 mm, 1 degree = 0.0175 rad.
Note: $a = 4$ feet in all cases.

FIGURE R301.2(8)
COMPONENT AND CLADDING PRESSURE ZONES
FIGURE R301.2(5)A
ULTIMATE-DESIGN WIND-SPEEDS

Notes:
1. Values are annual design 3-second gust wind speeds in miles per hour (mph) at 33 ft (10m) above ground for Exposure C category.
2. Interpolation between contours is permitted.

- Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.

Wind speeds correspond to approximately a 7% probability of exceedance in 50 years. Annual Exceedence Probability = 0.00143, MRI = 70.
FIGURE R301.2(5)A
ULTIMATE DESIGN WIND SPEEDS

Revise as follows:

Notes:
1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation is permitted between contours. Point values are provided to aid with interpolation.
3. Islands, coastal areas, and land boundaries outside the last contour shall use the last wind speed contour.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years (Annual Exceedance Probability = 0.00143, MRI = 700 Years).
6. Location-specific basic wind speeds shall be permitted to be determined using www.atcouncil.org/windspeed
Reason: This proposal coordinates the wind design criteria in the IRC with currently referenced 2016 edition of the loading standard *ASCE 7 Minimum Design Loads and Associated Criteria for Buildings and Other Structures* (ASCE 7-16). There are two primary proposed changes to the IRC for coordination with the revised wind loading criteria in ASCE 7-16: (1) updated basic wind speed maps for Risk Category II buildings and (2) revised roof component and cladding loads for buildings with mean roof heights less than or equal to 60 feet.

(1) Updated Map:

In ASCE 7-16, wind speeds in non-hurricane prone areas of the contiguous United States have been revised using contours to better reflect the regional variation in the extreme wind climate. Point values are provided to aid interpolation, in a style similar to that used for the other hazard maps in ASCE 7. Summaries of the data and methods used to estimate both the non-hurricane and hurricane wind speeds are provided in the Commentary to ASCE 7-16 Chapter 26 (attached to this proposal). The wind speeds in the hurricane-prone region have not changed from ASCE 7-10, the previous edition. Revised Figure R301.2(4)A is the wind speed map from ASCE 7-16 for Risk Category II Buildings.

Update to R301.2(4)B removes the notes, only.

(2) Revised Tables:

The simplified component and cladding loads in Table R301.2(2) are proposed to be revised for correlation with the new roof component and cladding loads for buildings with mean roof heights less than or equal to 60 feet. The roof zones and pressure coefficients in ASCE 7-16 Figure 30.4-2 (which includes Figures 30.4-2A through
30.4-2I) have been revised based on an analysis of an extensive wind tunnel database. All source data used in
the study are publically accessible thought the National Institute of Standards and Technology (NIST) website.
Compared to previous versions of ASCE 7, the pressure coefficients have been increased, and are now more
consistent with coefficients for buildings higher than 60 feet. Roof zones sizes are also modified from those of
earlier versions in order to minimize the increase of pressure coefficients in Zones 1 and 2. The data indicate
that for these low-rise buildings, the size of the roof zones depend primarily on the building height, h. The GCp
values given in ASCE 7-16 Figures 30.4-2A through 30.4-2I are associated with wind tunnel tests performed in
both Exposure B and C. For ASCE 7-16 Figure 30.4-2A, the coefficients apply equally to Exposure B and C,
based on wind tunnel data that show insignificant difference in (GCp) for Exposure B and C. Consequently, the
truncation for Kz in Table 30.3-1 of ASCE 7-10 is not required for building below 30 feet, and the lower Kz values
may be used as shown revised in Figure R301.2(3) of the IRC. More explanation is found in the Commentary to
ASCE 7-16 Chapter 30 (attached to this proposal).

NOTE: Due to cdpAccess functionality, the revised table was added as a NEW table, however, it is intended to
replace the existing R301.2(2). Also, in the NEW table, only footnotes f and g are NEW. The footnotes a to e
remain unchanged from previous IRC, but only look new due to cdpAccess legislative format editor.

Cost Impact: The code change proposal will increase the cost of construction
Component and cladding loads for roofs in buildings with mean roof heights less than or equal to 60 feet are
higher for some roof slopes and zones than for similar roof slopes in 2018 IRC. Construction costs will increase
for roofing products and decking for some areas of the country in the hurricane-prone region. However, for
much of the country outside the hurricane-prone region, the wind speeds are actually lower and therefore even
with an increase in GCp, the loads do not change and there is no impact on costs. Also, loads for wall
components such as windows, doors, siding, etc., are lower for mean roof height under 30 feet. Loads on Main
Wind Force Resisting Systems, such as shear walls and diaphragms, are decreasing in areas where the design
wind speed has decreased.
Proponent: Jennifer Goupil, American Society of Civil Engineers (ASCE), representing American Society of Civil Engineers (ASCE) (jgoupil@asce.org); T. Eric Stafford, Insurance Institute for Business and Home Safety (testafford@charter.net); Don Scott, PCS Structural Solutions, representing National Council of Structural Engineers Association (dscott@pcs-structural.com)

2018 International Residential Code

Revise as follows:

R301.2.1 Wind design criteria. Buildings and portions thereof shall be constructed in accordance with the wind provisions of this code using the ultimate design wind speed in Table R301.2(1) as determined from Figure R301.2(5)A. The structural provisions of this code for wind loads are not permitted where wind design is required as specified in Section R301.2.1.1. Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where not otherwise specified, the wind loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.4. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 from the roof assembly to the foundation. Where ultimate design wind speeds in Figure R301.2(4)A are less than the lowest wind speed indicated in the prescriptive provisions of this code, the lowest wind speed indicated in the prescriptive provision of this code shall be used.

TABLE AH106.4(1)
DESIGN WIND Pressures FOR SCREEN ENCLOSURE FRAMING

<table>
<thead>
<tr>
<th>LOAD CASE</th>
<th>WALL</th>
<th>ULTIMATE DESIGN WIND SPEED, $V_{ult}$ (mph)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A&lt;sup&gt;C&lt;/sup&gt;</td>
<td>Windward and leeward walls (flow thru) and windward wall (nonflow thru) L/W = 0-1</td>
<td>5</td>
</tr>
</tbody>
</table>
Design pressure shall be not less than 10 psf in accordance with Section AH106.4.1.

a. Loads are applicable to screen enclosures with a mean roof height of 30 feet or less in Exposure B. For screen enclosures of different heights or exposure, the pressures given shall be adjusted by multiplying the table pressure by the adjustment factor given in Table AH106.4(2).

b. For Load Case A flow thru condition, the pressure given shall be applied simultaneously to both the upwind and downwind screen walls acting in the same direction as the wind. The structure shall be analyzed for wind coming from the opposite direction. For the nonflow thru condition, the screen enclosure wall shall be analyzed for the load applied acting toward the interior of the enclosure.

c. For Load Case B, the table pressure multiplied by the projected frontal area of the screen enclosure is the total drag force, including drag on screen surfaces parallel to the wind, that must be transmitted to the ground. Use Load Case A for members directly supporting the screen surface perpendicular to the wind. Load Case B loads shall be applied only to structural members that carry wind loads from more than one surface.

d. The roof structure shall be analyzed for the pressure given occurring both upward and downward.

e. Table pressures are MWFRS loads. The design of solid roof panels and their attachments shall be based on component and cladding loads for enclosed or partially enclosed structures as appropriate.

f. Table pressures apply to 20-inch by 20-inch by 0.013-inch mesh screen. For 18-inch by 14-inch by 0.013-inch mesh screen, pressures on screen surfaces shall be permitted to be multiplied by 0.88. For screen densities greater than 20 inches by 20 inches by 0.013 inch, pressures for enclosed buildings shall be used.

g. Linear interpolation shall be permitted.
Notes:

1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation is permitted between contours. Point values are provided to aid with interpolation.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedence in 50 years (Annual Exceedence Probability = 0.00143, MRI = 700 Years).
6. Location-specific basic wind speeds shall be permitted to be determined using www.atcouncil.org/windspeed

**FIGURE AH106.4.1**

ULTIMATE DESIGN WIND SPEEDS FOR PATIO COVERS AND SCREEN ENCLOSURES

Reason: This proposal is a coordination proposal to accompany the proposal to update the wind map in Figure R301.2(4)A to the currently referenced ASCE 7-16 standard. As has been stated, the ASCE 7-16 wind maps include many areas of the country where wind speeds decreased below the speeds of the previous maps. To coordinate the IRC with the areas of lower wind speeds, this proposal adds or modifies existing provisions to account for these lower speeds. This proposal includes several changes that are bundled together in one proposal because they all reflect the effort to accommodate for these lower speeds in the existing tables and
figures. Each change within this proposal is explained below.

**R301.2.1 Wind design criteria.**
The last sentence was added to acknowledge the lower speeds and permit use of the prescriptive provisions.

**Table R301.2.1.5.1 Ultimate Design Wind Speed Modification for Topographic Wind Effect**
Three new lines are added to this table to accommodate the lower wind speeds of 95, 100, and 105mph.

**Table R602.10.1.3 Braced Wall Line Spacing**
Revision to this table includes removing the lower boundary of 100 mph to account for lower speeds now included on the map.

**Table R602.10.3(1) Bracing Requirements Based on Wind Speed**
This additional data is added to accommodate the lower wind speeds of <95mph.

**Table R602.10.6.4 Tension Strap Capacity for Resisting Wind Pressures Perpendicular to Methods PFH, PFG and CS-PF Braces Wall Panels**
The small revision to this table is to add “\(\leq\)” to the lowest wind speed of 110, for both Exposure B and C, to indicate this is appropriate for use with lower wind speeds.

**Table R703.3.2 Limits for Attachment Per Table R703.3(1)**
This table was updated to include new lines for lower wind speeds of 95, 100, 105, and 110.

**Table AH106.4(1) Design Wind Pressures for Screen Enclosures Framing**
This update adds columns for lower wind speeds of 90 and 95 mph.

**Figure AH106.4.1 Ultimate Design Wind Speeds for Patio Covers and Screen Enclosures**
This updates the map to the ASCE 7-16 RC I MRI=300 years map.

**Cost Impact:** The code change proposal will decrease the cost of construction
By updating and adding in prescriptive provisions to reflect the lower wind speeds that appear in some areas of the country, this proposal on its own will lower construction costs. However, as this is a coordination proposal, the impacts of this proposal will depend on the situation and overall design.

Proposal # 5476

RB36-19
**R301.2.1.1 Wind limitations and wind design required.** The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(5)B or where the ultimate design wind speed, $V_{ult}$, in Figure R301.2(5)A equals or exceeds 140 mph in a special wind region.

**Exceptions:**

1. For concrete construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R404 and R608.
2. For structural insulated panels, the wind provisions of this code shall apply in accordance with the limitations of Section R610.
3. For cold-formed steel light-frame construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R505, R603 and R804.

In regions where wind design is required in accordance with Figure R301.2(5)B or where the ultimate design wind speed, $V_{ult}$, in Figure R301.2(5)A equals or exceeds 140 mph in a special wind region, the design of buildings for wind loads shall be in accordance with one or more of the following methods:

4. **AISI Standard for Cold-Formed Steel Framing—Prescriptive Method For One- and Two-Family Dwellings** (AISI S230).
5. **International Building Code**.

The elements of design not addressed by the methods in Items 1 through 5 shall be in accordance with the provisions of this code.

Where ASCE 7 or the International Building Code is used for the design of the building, the wind speed map and exposure category requirements as specified in ASCE 7 and the International Building Code shall be used.

**Reason:** This is one of a series of proposals to correct some errors regarding the applicability of the IRC to areas where wind speeds exceed the prescriptive provisions established by the IRC. Figure R301.2(5)B prohibits the use the prescriptive provisions in the IRC in the shaded areas of the map which are referred to as the "wind design required regions." The wind design required region in Figure R301.2(5)B essentially covers hurricane prone regions and other coastal areas where the wind speed exceeds 130 mph or 140 mph depending on location. However, the code does not explicitly prohibit the use of the prescriptive provisions in the IRC in special wind regions for any wind speed. This discrepancy is primarily due to changes in the 2015 IRC that introduced the strength design level wind speeds from ASCE 7-10 in Figure R301.2(5)A and coordinated with the wind design required map in Figure R301.2(5)B. The wind limitations in the 2012 IRC stated the following:
R301.2.1.1 Wind limitations and wind design required. The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(4)B or where the basic wind speed from Figure R301.2(4) equals or exceeds 110 miles per hour (49 m/s).

By providing a wind speed limitation, in addition to the wind design required map, the prescriptive provisions of the IRC would have been prohibited in special wind regions where the wind speed exceeded 110 mph in the 2012 IRC. A similar limitation does not exist in the 2018 IRC. The current language in the 2018 IRC is in error and this proposal simply restores the limitation in the special wind regions that existed prior to the 2015 IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal will not increase the cost of construction as it simply corrects an error and restores a limitation that existed in the 2012 IRC and previous editions.
R301.2.1.1 Wind limitations and wind design required. The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(5)B.

Exceptions:

1. For concrete construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R404 and R608.
2. For structural insulated panels, the wind provisions of this code shall apply in accordance with the limitations of Section R610.
3. For cold-formed steel light-frame construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R505, R603 and R804.

In regions where wind design is required in accordance with Figure R301.2(5)B, the design of buildings for wind loads shall be in accordance with one or more of the following methods:

1. AWC Wood Frame Construction Manual (WFCM).
2. ICC Standard for Residential Construction in High-Wind Regions (ICC 600).
4. AISI Standard for Cold-Formed Steel Framing—Prescriptive Method For One- and Two-Family Dwellings (AISI S230).

The elements of design not addressed by the methods in Items 1 through 5 shall be in accordance with the provisions of this code.

Where ASCE 7 or the International Building Code is used for the design of the building, the wind speed map and exposure category requirements as specified in ASCE 7 and the International Building Code shall be used.

The prescriptive construction provisions of Chapters 4 through 9 of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(5)B.

Exceptions:

1. For concrete construction, the provisions of this code apply in accordance with the limitations of Sections and R608.
2. For structural insulated panels, the provisions of this code shall apply in accordance with the limitations of Section R610.
3. For cold-formed steel light-frame construction, the provisions of this code shall apply in accordance with the limitations of Sections R505, R603 and R804.

4. For exterior wall coverings and soffits, the provisions of this code shall apply in accordance with the limitations of Section R703.3.2.

5. For roof coverings, the provisions of this code shall apply in accordance with Chapter 9.

6. For exterior windows and doors, the provisions of this code shall apply in accordance with Section R609.

7. The seismic requirements of Chapters 4 through 9 apply in accordance with the scope of Section R301.2.2.

**Reason:** This proposal is one of two proposals intended to clarify the wind limitations in the IRC. Currently, the IRC contains an assortment of requirements for wind loads scattered throughout the code. While Section R301.2.1.1 intends to limit the applicability of the IRC to areas where wind design is not required in accordance with Figure R301.2(5)B, it’s not very clear what exactly applies in the IRC in regions where wind design is required. Current Section R301.2.1.1 states that the “wind provisions” of this code do not apply where wind design is required but is not clear anywhere in the code as to what the wind provisions in this code do apply to. The use of the phrase “wind provisions of this code” is very confusing. Clearly the prescriptive fastening schedule in Table R602.3(1) should not apply where wind design is required. However, it’s not very clear that this table is actually part of the “wind provisions in this code.” This proposal makes it clear that the prescriptive provisions in Chapters 4 through 9 do not apply where wind design is required. Provisions in the IRC that do apply to higher wind regions than indicated by Figure R301.2(5)B have been consolidated into the Exceptions to Section R301.2.1.1. The language that applies to elements of design not addressed by the methods in Items 1 through 5 of Section R301.2.1.1 is maintained by this proposal. Therefore, Section R405 (foundation drainage), Section R406 (dampproofing and waterproofing provisions), Section R702 (interior coverings), Section R806 (roof ventilation), Section R807 (attic access) and others would apply as specified in the code. Additionally, this proposal reorders the language so that the code tells the user directly what is required to be used when located in a wind design required region (WFCM, ICC 600, ASCE 7, AISI S230, and/or IBC). This improves the flow of the language and is similar to the approach used in the 2000, 2003, 2006 and 2009 IRC.

Lastly, a new exception is proposed to be added that clarifies that the seismic requirements in the code, including the scope as specified in Section R301.2.2, apply regardless.

This proposal is not intended to change any technical requirements in the IRC related to wind design. It is intended to simply clarify the wind limitations in the IRC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code change proposal will not impact the cost of construction as it is simply a clarification.
2018 International Residential Code

Revise as follows:

R301.2.2.1.1 Alternate determination of seismic design category. The seismic design categories and corresponding short-period design spectral response accelerations, \( S_{DS} \), shown in Figure R301.2(2), are based on soil Site Class D, used as an assumed default, as defined in Section 1613.2.2 of the International Building Code. If soil conditions are determined by the building official to be Site Class A, B, or D, the seismic design category and short-period design spectral response accelerations, \( S_{DS} \), for a site shall be allowed to be determined in accordance with Figure R301.2(3), or Section 1613.2 of the International Building Code. The value of \( S_{DS} \) determined in accordance with Section 1613.2 of the International Building Code is permitted to be used to set the seismic design category in accordance with Table R301.2.2.1.1, and to interpolate between values in Tables R602.10.3(3), R603.9.2(1) and other seismic design requirements of this code.

Reason: The intent of this change proposal is to delete unnecessary and potentially confusing language. The proponent of this change authored Section R301.2.2.1.1 in the last code update cycle. The wording being struck has since been identified by users to be confusing. The authors have determined that the wording being struck is commentary and is not needed for proper implementation of the IRC provisions.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

No cost impact as this is an editorial change to remove potential user confusion.
2018 International Residential Code

Add new definition as follows:

**CRIPPLE WALL CLEAR HEIGHT.** The vertical height of a *cripple wall* from the top of the foundation to the underside of floor framing above.

Revise as follows:

R301.2.2.6 Irregular buildings. The seismic provisions of this code shall not be used for structures, or portions thereof, located in Seismic Design Categories C, D<sub>0</sub>, D<sub>1</sub> and D<sub>2</sub> and considered to be irregular in accordance with this section. A building or portion of a building shall be considered to be irregular where one or more of the conditions defined in Items 1 through 7 occur. Irregular structures, or irregular portions of structures, shall be designed in accordance with accepted engineering practice to the extent the irregular features affect the performance of the remaining structural system. Where the forces associated with the irregularity are resisted by a structural system designed in accordance with accepted engineering practice, the remainder of the building shall be permitted to be designed using the provisions of this code.

**Exceptions:** Fireplaces, chimneys and masonry veneer in accordance with this code.

1. **Shear wall or braced wall offsets out of plane.** Conditions where exterior shear wall lines or *braced wall panels* are not in one plane vertically from the foundation to the uppermost story in which they are required.

   **Exception:** For wood light-frame construction, floors with cantilevers or setbacks not exceeding four times the nominal depth of the wood floor joists are permitted to support *braced wall panels* that are out of plane with *braced wall panels* below provided that all of the following are satisfied:

   1. Floor joists are nominal 2 inches by 10 inches (51 mm by 254 mm) or larger and spaced not more than 16 inches (406 mm) on center.
   2. The ratio of the back span to the cantilever is not less than 2 to 1.
   3. Floor joists at ends of *braced wall panels* are doubled.
   4. For wood-frame construction, a continuous rim joist is connected to ends of cantilever joists. Where spliced, the rim joists shall be spliced using a galvanized metal tie not less than 0.058 inch (1.5 mm) (16 gage) and 1 1/2 inches (38 mm) wide fastened with six 16d nails on each side of the splice; or a block of the same size as the rim joist and of sufficient length to fit securely between the joist space at which the splice occurs, fastened with eight 16d nails on each side of the splice.
   5. Gravity loads carried at the end of cantilevered joists are limited to uniform wall and roof loads and the reactions from headers having a span of 8 feet (2438 mm) or less.
2. Lateral support of roofs and floors. Conditions where a section of floor or roof is not laterally supported by shear walls or braced wall lines on all edges.

Exception: Portions of floors that do not support shear walls, braced wall panels above, or roofs shall be permitted to extend not more than 6 feet (1829 mm) beyond a shear wall or braced wall line.

3. Shear wall or braced wall offsets in plane. Conditions where the end of a braced wall panel occurs over an opening in the wall below and extends more than 1 foot (305 mm) horizontally past the edge of the opening. This provision is applicable to shear walls and braced wall panels offset in plane and to braced wall panels offset out of plane in accordance with the exception to Item 1.

Exception: For wood light-frame wall construction, one end of a braced wall panel shall be permitted to extend more than 1 foot (305 mm) over an opening not more than 8 feet (2438 mm) in width in the wall below provided that the opening includes a header in accordance with all of the following:

1. The building width, loading condition and framing member species limitations of Table R602.7(1) shall apply.
2. The header is composed of:
   2.1. Not less than one 2 × 12 or two 2 × 10 for an opening not more than 4 feet (1219 mm) wide.
   2.2. Not less than two 2 × 12 or three 2 × 10 for an opening not more than 6 feet (1829 mm) in width.
   2.3. Not less than three 2 × 12 or four 2 × 10 for an opening not more than 8 feet (2438 mm) in width.
3. The entire length of the braced wall panel does not occur over an opening in the wall below.

4. Floor and roof opening. Conditions where an opening in a floor or roof exceeds the lesser of 12 feet (3658 mm) or 50 percent of the least floor or roof dimension.

5. Floor level offset. Conditions where portions of a floor level are vertically offset.

Exceptions:

1. Framing supported directly by continuous foundations at the perimeter of the building.
2. For wood light-frame construction, floors shall be permitted to be vertically offset where the floor framing is lapped or tied together as required by Section R502.6.1.

6. Perpendicular shear wall and wall bracing. Conditions where shear walls and braced wall lines do not occur in two perpendicular directions.

7. Wall bracing in stories containing masonry or concrete construction. Conditions where stories above grade plane are partially or completely braced by wood wall framing in accordance with Section R602 or cold-formed steel wall framing in accordance with Section R603 include masonry or concrete construction. Where this irregularity applies, the entire story shall be designed in accordance with accepted engineering practice.

Exception: Fireplaces, chimneys and masonry veneer in accordance with this code.

8. Hillside Light-Frame Construction. Light-frame construction in which both Items 1 and 2 below apply:

1. The grade slope exceeds 1 vertical in 5 horizontal where averaged across the full length of any side of the dwelling, and
2. The tallest cripple wall clear height exceeds 7'-0" or where a post and beam
System occurs at the dwelling perimeter, the post and beam system tallest post clear height exceeds 7'-0".

Exception: Light-frame construction in which the lowest framed floor is supported directly on concrete or masonry walls over the full length of all sides except the downhill side of the dwelling need not be considered an irregular dwelling under Item 8.

Reason: As part of work contributing to FEMA P-1100 (Vulnerability-Based Seismic Assessment and Retrofit of One- and Two-Family Dwellings Volume 1 - Prestandard), it was identified that for light-frame dwellings on steep hillsides (Figure 1), adequate seismic performance does not occur when seismic design is based on typical seismic force distribution assumptions (tributary area, flexible diaphragm). Whether loading is in the cross-slope or out-of-hill direction (Figure 2), seismic forces follow the stiffest load path to the uphill foundation, rather than distributing uniformly to all the bracing walls in the way assumed in development of IRC seismic bracing provisions. For this reason, design using the IRC bracing provisions will not provide adequate seismic performance. This change proposal triggers an engineered lateral force design for hillside dwellings by adding the hillside dwelling configuration to the already existing list of configurations deemed to be irregular for seismic design purposes.

This dwelling configuration was illustrated to be vulnerable in the 1994 Northridge, California Earthquake. The Earthquake Spectra Northridge Earthquake Reconnaissance Report (Volume 2, EERI, 1996) reported 117 significantly damaged hillside dwellings of the bearing wall type and 40 of the post and beam (stilt) type. Fifteen dwellings were reported to have collapsed or were so near collapse that they were immediately demolished and another fifteen came close to collapsing. HUD (1994) also reported significant damage to hillside dwellings. As examples of vulnerable hillside dwelling performance, Figure 3 illustrates a dwelling that pulled about six inches away from the uphill foundation, but did not collapse, and Figure 4 illustrates one of the collapsed dwellings.

Blaney et. Al (2018), illustrates results from numerical studies used in development of FEMA P-1100. Figure 18 of this reference indicates that for a studied hillside dwelling, the probability of collapse in the risk-adjusted maximum considered earthquake (MCER) was reduced by more than a factor of seven by changing from typical prescriptive bracing practice to an engineered methodology that considered the seismic response. More background on dwelling past performance and the numerical studies are found in FEMA P-1100.

The Item 1 grade slope trigger is used to limit applicability of this irregularity to dwellings that are on sites with a significant slope (Figure 5). Averaging the grade slope along the side of the dwelling is intended to focus on the overall drop in grade elevation across the dwelling and not trigger the irregularity based only on limited areas of higher grade slope. This is consistent with the numerical studies that form the basis of this proposal. For most dwellings this criterion will be evaluated by looking at each of the four primary elevations. For large and more complex dwellings, additional “sides” will need to be evaluated.

Item 2 adds a second trigger of downhill cripple wall height greater than 7'-0" (Figure 6) or downhill post clear height in post and pier dwelling (Figure 7) based on the FEMA P-1100 numerical studies. Both Items 1 and 2 need to be triggered in order to qualify for dwelling to be qualified as irregular. These triggers were observed to be the points at which damage and displacements at the uphill foundation were thought to significantly increase the likelihood of collapse.

The exception scopes out of irregularity Item 8 dwellings that have full-height concrete or masonry walls (Figure 8) because this configuration was not part of the numerical studies that form the basis of this proposal. For a dwelling with a simple rectangular floor plan, full height concrete or masonry walls would need to occur on three sides to qualify for the exception. For a more complex dwelling plan configuration, additional concrete or masonry walls would be required to qualify for the exception. Dwellings with doors and windows in the concrete or masonry walls still qualify for the exception. In all dwellings the concrete or masonry walls will need to conform to applicable IRC provisions.

Figure 3. Hillside dwelling pulled away from uphill foundation in the 1994 Northridge, California Earthquake (Credit: City of Los Angeles Department of Building and Safety). Red arrow shows location where floor framing has pulled six to eight inches away from the uphill foundation.

Figure 4. Hillside dwelling collapsed in the 1994 Northridge, California Earthquake (Credit: City of Los Angeles Department of Building and Safety).
Figure 5. Grade slope triggering the hillside dwelling irregularity exceeds 1 vertical in 5 horizontal across the full width of any side of the dwelling.

Figure 6. Downhill cripple wall height triggering the hillside dwelling irregularity.

Figure 7. Downhill post height triggering the hillside dwelling irregularity.
Figure 8. Concrete or masonry wall configuration that does not tripper the hillside dwelling irregularity.

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal is anticipated to increase the number of dwellings required to have an engineered lateral force design for moderately steep to very steep sites. In regions where these dwellings are believed to already be predominantly engineered, the cost impact is thought to be negligible. In other regions where these dwellings are not predominantly engineered, additional costs will be incurred for engineered design and more robust anchorage to the foundation.
Proponent: Kelly Cobeen, Wiss Janney Elstner Associates, representing Federal Emergency Management Agency and Applied Technology Council Seismic Code Support Committee (FEMA/ATC SCSC) (KCobeen@wje.com); Julie Furr, Rimkus Consulting Group, representing Federal Emergency Management Agency and Applied Technology Council Seismic Code Support Committee (FEMA/ATC SCSC) (jfurr@rimkus.com); Michael Mahoney, representing Federal Emergency Management Agency (mike.mahoney@fema.dhs.gov)

2018 International Residential Code

Revise as follows:

R301.2.2.7 Height limitations. Wood-framed buildings shall be limited to three stories above grade plane or the limits given in Table R602.10.3(3). Wood-framed buildings in Seismic Design Category D exceeding two stories shall be designed for wind and seismic loads in accordance with accepted engineering practice. Cold-formed steel-framed buildings shall be limited to less than or equal to three stories above grade plane in accordance with AISI S230. Mezzanines as defined in Section R202 that comply with Section R325 shall not be considered as stories. Structural insulated panel buildings shall be limited to two stories above grade plane.

Reason: This proposal adds language in the seismic scopeing provisions of Section R301.2.2 to clearly communicate that three-story dwellings in SDC D2 are beyond the scope of the IRC wall bracing provisions. This limitation already exists based on the Section R602.10 bracing tables, however it is more appropriate for this to be in a text provision, and it is more beneficial to the user to make this limit clear in Chapter 3 so as to remove all ambiguity prior to reading Chapter 6.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. No cost impact. This is an editorial clarification of the intent of current provisions.
Proponent: Stephanie Young, representing National Council of Structural Engineers Associations (stephanie@mattsonmacdonald.com)

2018 International Residential Code

Revise as follows:

R301.2.2.10 Anchorage of water heaters. In Seismic Design Categories D₀, D₁ and D₂, and in townhouses in Seismic Design Category C, water heaters and thermal storage units shall be anchored against movement and overturning in accordance with Section M1307.2, M1307.2 or P2801.8.

Reason: In Section M1307.2, appliances consist of both water heaters and thermal storage tanks. Also, Section M1307.2 applies not only to Seismic Design Categories D₀, D₁ and D₂, but also to townhouses in Seismic Design Category C. This code change is presented to coordinate Sections R301.2.2.10 and M1307.2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Clarifying language only, no change to actual design or construction requirements for appliance bracing.

Proposal # 4598
R301.3 Story height. The wind and seismic provisions of this code shall apply to buildings with *story heights* not exceeding the following:

1. For wood wall framing, the *story height* shall not exceed 11 feet 7 inches (3531 mm) and the laterally unsupported bearing wall stud height permitted by Table R602.3(5).
   **Exception:** A story height not exceeding 13 feet 7 inches is permitted provided the maximum wall stud clear height does not exceed 12 feet (3658 mm), the wall studs are in accordance with Exception 2 or Exception 3 of Section R602.3.1 or an engineered design is provided for the wall framing members, and wall bracing for the building is in accordance with Section R602.10.

2. For cold-formed steel wall framing, the *story height* shall be not more than 11 feet 7 inches (3531 mm) and the unsupported bearing wall stud height shall be not more than 10 feet (3048 mm).

3. For masonry walls, the *story height* shall be not more than 13 feet 7 inches (4140 mm) and the bearing wall clear height shall be not more than 12 feet (3658 mm).
   **Exception:** An additional 8 feet (2438 mm) of bearing wall clear height is permitted for gable end walls.

4. For insulating concrete form walls, the maximum story height shall not exceed 11 feet 7 inches (3531 mm) and the maximum unsupported wall height per *story* as permitted by Section R608 tables shall not exceed 10 feet (3048 mm).

5. For structural insulated panel (SIP) walls, the story height shall be not more than 11 feet 7 inches (3531 mm) and the bearing wall height per *story* as permitted by Section R610 tables shall not exceed 10 feet (3048 mm).

For walls other than wood-framed walls, individual walls or wall studs shall be permitted to exceed these limits as permitted by Chapter 6 provisions, provided that the *story heights of this section* are not exceeded. An engineered design shall be provided for the wall or wall framing members where the limits of Chapter 6 are exceeded. Where the *story height* limits of this section are exceeded, the design of the building, or the noncompliant portions thereof, to resist wind and seismic loads shall be in accordance with the International Building Code.

Reason: The purpose of this code change is to finally address a long-standing conflict and point of confusion in the IRC story height provisions and restore the original intent of the IRC.

In the 2003 through 2006 IRC, the default provisions of Section R301.3 specified wood-frame buildings could have a maximum bearing wall stud height of 10 feet supporting framing members not exceeding 16” in depth. An exception allowed a maximum bearing wall stud height of 12 feet provided an engineered design for the wall and studs was provided for everything other than the wall bracing for wind and seismic loads, which could be determined per Section R602.10 with adjustment factors to increase the bracing amounts for the higher walls.

For the 2009 IRC, a successful proposal from SBCA revised Section R301.3 to allow floor framing members (e.g. I-joists or trusses) deeper than 16” to be used if the bearing wall stud height was less than 10 feet. This
was accomplished by specifying an overall story height limit of 11'-7", or the sum of a 10'-0" tall stud, 2x top and bottom plates, and 16" deep framing.

This technically overrode the exception allowing bearing wall studs up to 12 feet with wall bracing per the Section R602.10 adjustment factors and engineering design otherwise, not to mention conflicting with the 12 foot bearing wall height limit for masonry walls and additional 8 feet allowed for gable end walls. However, to our recollection this was not brought up in floor testimony, committee discussion, or in public comments, and the change passed.

For the 2015 IRC, the BCAC further revised this section by deleting the 11'-7" story height limit from the final paragraph of Section R301.3 and placing it in each of the individual items to which it applied. This addressed the conflict with masonry walls but still did not fix the conflict with Section R602.10. To make matters worse, former members of the ICC Ad-Hoc Wall Bracing Committee advanced a proposal to delete the entire exception for bearing wall studs up to 12 feet out of concern code users would double-count the multipliers on the wall bracing, which are reflected in the respective tables of adjustment factors for wind and seismic bracing. Neither the BCAC nor the former AHC-WB members provided a fix for the conflict between the story height limits and the wall bracing provisions.

For the 2018 IRC, NAHB added the new Table R602.3(6) allowing bearing wall studs up to 12 feet in height for limited cases. We still did not directly address the conflict between the story height limits and the wall bracing provisions, let alone the conflict with the new table. In essence, NAHB (and others modifying Section R301.3) have relied on the statement in the last paragraph that individual walls or wall studs could exceed the limits of R301.3 as long as overall story heights were not exceeded.

This proposal generally restores the exception present in the 2000 through 2012 IRC stating “the wall stud clear height used to determine the maximum permitted story height may be increased to 12 feet without requiring an engineered design for the building wind and seismic force resisting systems” provided R602.10 is complied with, including mandated increases for stud heights up to 12 feet. At the same time, language is added pointing to the two exceptions to 10 foot bearing wall heights under Section R602.3, including the exception leading to the new Table R602.3(6). This will provide a critical link to both exceptions that is currently missing in the 2018 IRC. The requirement to use engineering design for studs in these tall walls not otherwise complying with one of the two exceptions to Section R602.3 is maintained.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The code change will not increase cost for builders in jurisdictions making a jump from the 2006 IRC or earlier directly to the 2021 IRC. The code change will also not increase cost for builders using subsequent editions and interpreting the language allowing individual walls or wall studs to exceed the limits of Section R301.3 to permit certain walls (e.g. foyers, great rooms, garages) to exceed the 11'-7" story height limit provided the average story height remains within the limit. The code change may decrease the cost of construction for builders who have been forced to hire structural engineers to design the lateral force-resisting system for houses with 11 or 12 foot bearing walls that would have met the 2000 through 2006 IRC but were excluded from the structural provisions of the IRC due to a strict interpretation of the language in the 2009 IRC and subsequent editions.

Proposal # 4713

RB43-19
2018 International Residential Code

R301.5 Live load. The minimum uniformly distributed live load shall be as provided in Table R301.5.

Revise as follows:

<table>
<thead>
<tr>
<th>USE</th>
<th>LIVE LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uninhabitable attics without storage$^b$</td>
<td>10</td>
</tr>
<tr>

<td>40$^c$</td>
</tr>
</tbody>
</table>

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm$^2$, 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.
b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
c. Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.
d. A single concentrated load applied in any direction at any point along the top.
e. See Section R507.1 for decks attached to exterior walls.
f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.
g. Uninhabitable attics with limited storage are those where the clear height between joists and
rafters is 42 inches or greater, or where there are two or more adjacent trusses with web
configurations capable of accommodating an assumed rectangle 42 inches in height by 24
inches in width, or greater, within the plane of the trusses. The live load need only be applied to
those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30
   inches in length that is located where the clear height in the attic is not less than 30
   inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to
   12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly
distributed concurrent live load of not less than 10 pounds per square foot.

h. Glazing used in handrail assemblies and guards shall be designed with a safety factor of 4. The
   safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and
to the load on the in-fill components. These loads shall be determined independent of one
   another, and loads are assumed not to occur with any other live load.

R502.3 Allowable joist spans. Spans for floor joists shall be in accordance with Tables R502.3.1(1) and
R502.3.1(2). For other grades and species and for other loading conditions, refer to the AWC STJR.

R502.3.1 Sleeping areas and attic joists. Table R502.3.1(1) shall be used to determine the maximum
allowable span of floor joists that support sleeping areas and attics that are accessed by means of a fixed
stairway in accordance with Section R311.7 provided that the design live load does not exceed 30 pounds per
square foot (1.44 kPa) and the design dead load does not exceed 20 pounds per square foot (0.96 kPa). The
allowable span of ceiling joists that support attics used for limited storage or no storage shall be determined in
accordance with Section R802.5.

R502.3.2 Other floor joists. Table R502.3.1(2) shall be used to determine the maximum allowable span of
floor joists that support other areas of the building, other than sleeping rooms, areas and attics, provided that the
design live load does not exceed 40 pounds per square foot (1.92 kPa) and the design dead load does not
exceed 20 pounds per square foot (0.96 kPa).

R502.3.3 Floor cantilevers. Floor cantilever spans shall not exceed the nominal depth of the wood floor joist.
Floor cantilevers constructed in accordance with Table R502.3.3(1) shall be permitted where supporting a light-
frame bearing wall and roof only. Floor cantilevers supporting an exterior balcony are permitted to be
constructed in accordance with Table R502.3.3(2).

Reason: The purpose of this code change is to align the IRC with the IBC and ASCE 7 for live loads on dwelling
floors. Questions have been raised about the fact Table R301.5 refers to “sleeping rooms” and whether this
means the bathrooms, closets, hallways, and other non-bedroom spaces on the floor of a dwelling need to be
designed for a 40 psf live load even if the total area of bedrooms predominates.
Table 1607.1 of the IBC and Table 4.3-1 of ASCE 7 both apply the 30 psf live load to “habitable attics and
sleeping areas”. The IBC applies the 40 psf load to “all other areas”, ASCE 7 applies it to “all other areas
except stairs”. Both the IBC and ASCE 7 require 40 psf for stairs in one- and two-family dwellings, as does the
existing Table R301.5. There is no reason for the IRC to be more stringent than the IBC and ASCE 7. Further, it
is not the intent of the IRC to require the builder to apply a patchwork of different live loads across a floor
primarily consisting of bedrooms and wind up with different joist sizes and spacings just because some joists
happen to pass under bathrooms and closets as well as bedroom spaces and some do not.

This change also aligns Table R301.5 with Section R502.3.1 and R502.3.2 and the respective Tables
R502.3.1(1) and R502.3.1(2) for floor joists. Section R502.3.1 and Table R502.3.1(1), which is based on the 30 psf live load, refers specifically to “sleeping areas”. Table R502.3.1(3) refers to “living areas” and is based on a 40 psf live load. While not explicitly stated as such, the intent of “living areas” is clearly the same as “areas other than sleeping areas”. However, Section R502.3.2 appears to be an outlier in referring to “sleeping rooms”, and this proposal makes the correlating change to “sleeping areas”.

Further, this change aligns with both the traditional bearing wall footing table that was present in the 2000 through 2012 IRC and the revised and expanded tables in the 2015 and 2018 IRC. Both sets of tables apply a 40 psf load uniformly across the ground floor where dining rooms, living rooms, dens, etc. are typically located and 30 psf uniformly across the upper floor or floors that are dominated by bedrooms (i.e., sleeping rooms).

This change does not preclude a builder, building designer or registered design professional from conservatively designing all floors of the home to 40 psf regardless of whether a floor mostly consists of bedrooms used primarily for sleeping or rooms used primarily for dining, recreation, entertainment and other purposes. Many do so for serviceability (i.e., reduce deflections or “bounce” on the bedroom floors) or for the ease of design and potential economy of using the same floor framing sizes and layouts for all the floors. However, the IRC is intended to be a minimum code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change is primarily a clarification and maintains current minimum practice for the design of one- and two-family dwellings.

Proposal # 5074

RB44-19
2018 International Residential Code

Revise as follows:

### TABLE R301.5

**MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS (in pounds per square foot)**

<table>

<tr>
<td>Stairs</td>
<td>40</td>
</tr>
</tbody>
</table>

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm², 1 pound = 4.45 N.

- Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.
- Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
- Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.
- A single concentrated load applied in any direction at any point along the top.
- See Section R507.1 for decks attached to exterior walls.
- Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.
- Uninhabitable attics with limited storage are those where the clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.
The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

Glazing used in handrail assemblies and guards shall be designed with a safety factor of 4. The safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

**Reason:** This code change is intended to merely clean up a technical error in the existing language.

Item 2 of footnote "g" is technically incorrect. As currently written, it mixes "units" with "inches" which would be undefined. It should either say, "...2 inches vertical to 12 inches horizontal." or "...2 units vertical to 12 units horizontal.". The preferred option would be to use units as shown in the proposal.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal does not add or remove any existing code requirements. Therefore, there is no cost impact.
2018 International Residential Code

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm², 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.

b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

c. Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.

d. A single concentrated load applied in any direction at any point along the top.

e. See Section R507.1 for decks attached to exterior walls.

f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.

g. Uninhabitable attics with limited storage are those where the clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24
inches in width, or greater, within the plane of the trusses. The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

h. Glazing used in handrail assemblies and guards shall be designed with a safety factor of 4. The safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

i. For a guard system not required to serve as a handrail, a single concentrated load applied at any point along the top, in the vertical downward direction and in the horizontal direction toward the lower surface. For a guard also serving as a handrail, a single concentrated load applied in any direction at any point along the top.

Reason: The purpose of this proposal is to revise the load on guard systems for one- and two-family dwellings to align with common industry practice. Extensive discussion has occurred in recent code cycles on load requirements and details for guard systems on decks accessory to one- and two-family dwellings. In particular, the directions in which the 200 pound guard load needs to be applied has been a topic of debate.

The IRC and IBC define a guard as “a building component or a system of building components located near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to the lower level.” The ASCE definition of a guardrail system is very similar. Clearly, a fall from the edge of an unprotected deck to the ground, which can be as much as 10 feet or more, carries a much greater risk of injury than a fall backwards onto the surface of the deck, which is only a few feet.

Further, a guard system can be constructed without a handrail, as under both the IRC and IBC a handrail is only required at a flight of stairs, a ramp, a stepped aisle, or a ramped aisle. Nor is the top rail of a guard system required to be graspable by occupants of a deck or other elevated walking surface, unless the guard is specifically designed to also serve as a handrail. In fact, a guard need not even have a top rail unless specifically required by the codes or the reference standards for guard systems, or desired as part of the design of the guard system.

As such, industry standards such as ASTM D7032 for wood and plastic composite decks boards and guards (referenced in both the IBC and IRC) and code evaluation acceptance criteria such as ICC-ES AC 174 for deck boards and guardrails, call for applying the 200 pound load in the outward and downward directions only, not inward or upward and certainly not parallel to the guard. Despite this apparent deviation from the IRC, IBC and ASCE 7 load requirements, thousands of guard systems, when designed, tested, and constructed in accordance with these industry standards and acceptance criteria and used properly, have performed exceptionally well and have protected occupants of decks against falls from the deck.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change will recognize existing practices in the design and testing of guard systems as specified in ASTM D7032, ICC-ES AC 174 and other industry standards for guard systems and components. Manufacturers with existing products designed and tested to those standards will remain compliant with the IRC and will not need to conduct additional engineering or testing. If this change is not approved, manufacturers may eventually be required to test or design their products for additional load directions, which would substantially increase
cost.

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm\(^2\), 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.
b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
c. Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.
d. A single concentrated load applied in any direction at any point along the top. For a guard not required to serve as a handrail, the load need not be applied to the top element of the guard in a direction parallel to such element.
e. See Section R507.1 for decks attached to exterior walls.
f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.
g. Uninhabitable attics with limited storage are those where the clear height between joists and...
rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

h. Glazing used in handrail assemblies and guards shall be designed with a safety factor of 4. The safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

**Reason:** The purpose of this proposal is to revise the load on guard systems for one- and two-family dwellings to align with common industry practice. Extensive discussion has occurred in recent code cycles on load requirements and details for guard systems on decks accessory to one- and two-family dwellings. In particular, the directions in which the 200 pound guard load needs to be applied has been a topic of debate. The IRC and IBC define a guard as “a building component or a system of building components located near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to the lower level.” The ASCE 7 definition of a guardrail system is very similar. Clearly, a fall from the edge of an unprotected deck to the ground, which can be as much as 10 feet or more, carries a much greater risk of injury than a fall backwards onto the surface of the deck, which is only a few feet.

Further, a guard system can be constructed without a handrail, as under both the IRC and IBC a handrail is only required at a flight of stairs, a ramp, a stepped aisle, or a ramped aisle. Nor is the top rail of a guard system required to be graspable by occupants of a deck or other elevated walking surface, unless the guard is specifically designed to also serve as a handrail. In fact, a guard need not even have a top rail unless specifically required by the codes or the reference standards for guard systems, or desired as part of the design of the guard system.

As such, industry standards such as ASTM D7032 for wood and plastic composite decks boards and guards (referenced in both the IBC and IRC) and code evaluation acceptance criteria such as ICC-ES AC 174 for deck boards and guardrails, call for applying the 200 pound load in the outward and downward directions only, representing the most significant loads on a guard and the most significant directions in which a fall need be prevented. Since by code a guard need not meet the requirements of a handrail, these standards and criteria do not require the 200 pound load be applied in-line along the top of the rail. Despite this apparent deviation from the IRC, IBC and ASCE 7 load requirements, thousands of guard systems, when designed, tested, and constructed in accordance with these industry standards and acceptance criteria and used properly, have performed exceptionally well and have protected occupants of decks against falls from the deck.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm², 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting the uniformly distributed live load or a 2,000-pound load applied over a 20-square-inch area. Concentrated load applied on an area of 4 1/2 inches by 4 1/2 inches, whichever produces the greater stresses.

b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

c. Individual stair treads shall be designed for capable of supporting the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4-square 2 inches by 2 inches, whichever produces the greater stresses.

d. A single concentrated load applied in any direction at any point along the top.

e. See Section R507.1 for decks attached to exterior walls.

f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1
square foot. This load need not be assumed to act concurrently with any other live load requirement.

g. Uninhabitable attics with limited storage are those where the clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

h. Glazing used in handrail assemblies and guards shall be designed with a safety load adjustment factor of 4. The safety load adjustment factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

Reason: As currently presented, the title of Table R301.5 states that loads shown are uniformly distributed and are listed in pounds per square foot. This is incorrect as the guardrail and handrail loads shown are intended as concentrated loads. By splitting the loads into two columns, the Live Load table will more accurately represent the necessary information. It will also allow for loads only previously noted in the footnotes to be incorporated into the body of the table. These changes will make the IRC Live Load table more closely match the format and values of the ASCE7 and IBC Live Load tables. The language added to the footnote regarding garage slab design is intended to reiterate that both the uniform load condition as well as the concentrated load condition must be evaluated to determine the most severe case. This footnote will now more closely match that of the similar note indicated for determining the proper design load conditions for stair treads.

The has been much confusion regarding the use of of the words 'safety factor' when dealing with glazing used as handrails, guards, and infill components. 'Safety factors' and the use of them can be confusing as to whether you are using them from the load side or from the material strength side of the design. By changing the word 'safety' to 'load adjustment', it should be more apparent that the intent is to multiply the minimum design load found in the table by the factor indicated.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The modified language is only intended to clarify existing requirements.

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm<sup>2</sup>, 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting the uniformly distributed live load or a 2,000-pound load applied over a 20-square-inch area. Concentrated load applied on an area of 4 1/2 inches by 4 1/2 inches, whichever produces the greater stresses.

b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

c. Individual stair treads shall be designed capable of supporting the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches by 2 inches, whichever produces the greater stresses.

d. A single concentrated load applied in any direction at any point along the top.

e. See Section R507.1 for decks attached to exterior walls.

f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.
g. Uninhabitable attics with limited storage are those where the clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

h. Glazing used in handrail assemblies and guards shall be designed with a safety load adjustment factor of 4. The safety load adjustment factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

**Reason:** The language added to the title of the Table simply indicates that the table contains values other than 'pounds per square foot'.
The language added to the footnote regarding garage slab design is intended to reiterate that both the uniform load condition as well as the concentrated load condition must be evaluated to determine the most severe case. This footnote will now more closely match that of the similar note indicated for determining the proper design load conditions for stair treads.

The has been much confusion regarding the use of of the words 'safety factor' when dealing with glazing used as handrails, guards, and infill components. 'Safety factors' and the use of them can be confusing as to whether you are using them from the load side or from the material strength side of the design. By changing the word 'safety' to 'load adjustment', it should be more apparent that the intent is to multiply the minimum design load found in the table by the factor indicated.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The modified language is only intended to clarify existing requirements.

Proposal # 4599

RB49-19
2018 International Residential Code
Revise as follows:

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS (in pounds per square foot)

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>USE</th>
<th>LIVE LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balconies (exterior) and decks⁸</td>
<td>40</td>
</tr>
<tr>
<td></td>
<td>60</td>
</tr>
</tbody>
</table>

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm², 1 pound = 4.45 N.

a. Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.

b. Uninhabitable attics without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

c. Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.

d. A single concentrated load applied in any direction at any point along the top.

e. See Section R507.1 for decks attached to exterior walls.

f. Guard in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.

g. Uninhabitable attics with limited storage are those where the clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessed from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is not less than 30 inches.

2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.

3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.
h. Glazing used in handrail assemblies and guards shall be designed with a safety factor of 4. The safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

i. Where structural tables in Section R507 only specify snow loads, the values corresponding to 70 psf snow loads shall be used.

**Reason:** The purpose of this code change proposal is to align the IRC deck and balcony live load with the IBC and ASCE 7.

The new Footnote i is intended to coordinate this proposal with new tables for deck structure (beams, columns, and footings) we understand are being proposed by others. It is based on a discussion with one of the people who was involved with the development of the new tables.

While we realize this is a controversial issue, it is our opinion and judgment that there is no reason why the IRC should not align with IBC and ASCE 7, for the reasons following. For those who have not participated in the history of the issue, a summary of how we got to where we are is also below.

- ASCE 7 is the proper forum to debate and deliberate what live loads should be—they are the acknowledged experts. Deviating from ASCE 7 is substituting ICC’s judgment for the experts’ judgment.
- ASCE determined through their deliberative process 1.5 times the live load served is the prudent design live load.
- For all intents and purposes, what the IRC is doing is amending the reference standard—a practice that is frowned on in this process, unless it’s absolutely necessary.
- Deviating from ASCE 7 in this case is the beginnings of a slippery slope for other cases—on what basis do we decide to maintain or amend the current live load values for other areas of the building?
- Opposing arguments essentially revolve around “show me the bodies—we don’t have a history of failures.” Our counter to that is, this is a life-safety issue. Do we need or want to have bodies to show before we fix it?

**History:** For the first 3 versions of the IBC and IRC (2000 through 2006), deck and balcony live loads were separate items. In the IRC, decks were designed for 40 psf, and balconies were designed for 60 psf. The difference between decks and balconies was their supporting structure—decks were supported by posts, and balconies were cantilevered from the building.

In the 2009 IBC and IRC, through code change S9-06/07, the difference in live loads between decks and balconies was eliminated on the basis that how a structure is used should dictate the live load, not the support condition. Although several live loads were proposed for decks and balconies, through the code development process, both the IBC and the IRC ended up with a requirement for 40 psf.

During the development of the 2010 version of ASCE 7, in an attempt to keep IBC/IRC and ASCE 7 aligned, we submitted a proposal to the ASCE process to consolidate the deck and balcony loads into one item, and to change the deck and balcony live load to 40 psf. In their deliberative process, it became clear that in the professional judgment of many members of the relevant ASCE 7 committees, 40 psf was too low. While several live load proposals were suggested and debated, the proposal that everyone could agree on set deck and balcony live loads at 1.5 times the live load of the area served.

For the 2018 IBC, code change S85-16, submitted by ASCE, realigned the IBC deck and balcony loading with ASCE 7. For the 2018 IRC, the City of Seattle Department of Construction and Inspections (SDCI) and the Washington Association of Building Officials Technical Code Development Committee (WABO TCD) submitted proposals to realign IRC deck and balcony live loads with ASCE 7. Code change proposal R26-16 (SDCI’s
Code change proposal R27-16 (WABO TCD’s proposal) took a more simplified approach and set the live load at 60 psf—1.5 times the normal residential live load of 40 psf. The IRC-Building Committee gave direction that the more simplified approach was preferred, but disapproved R27-16 as well, partly because the prescriptive tables for deck/balcony structure had not been updated. SDCI and WABO TCD submitted a public comment on R27-16 to update the relevant tables, which received the necessary 2/3 majorities on the two votes to approve the modified item at the Public Comment Hearings. However, the proposal was ultimately disapproved through the subsequent online vote.

Cost Impact: The code change proposal will increase the cost of construction. As stated, increasing the live load will increase costs. The question is, how much? A full parametric study of every size, shape, and configuration of decks is not practical, as there are too many variables. However, there are several ways to show what the differences might be between a 40 psf design and a 60 psf design, which then leads to costs.

Case Studies

Using the tables in the 2018 IRC and the tables being proposed by others for the deck structure, I looked at two very simple designs, and compared the results for 40 psf live load with a 60 psf live load (= 70 psf ground snow load).
Case 1 (see Fig. 1) - 10’x20’ elevated deck. Height = 9’. Joists span 8’, with a 2’ cantilever. Two beams each spanning 10’ support the cantilevered end of the joists. The other end of the joists is supported by a ledger with ½” through-bolts and assume 1” of sheathing. Wood species assumed to be Hem-Fir (typical in the Pacific Northwest).

Case 2 (see Fig. 2) - 10’x15’ elevated deck. Everything is the same as Case 1, except instead of using two beams spanning 10’ between posts, a single beam spans 10’ between posts with 2’-6” cantilevers at each end to support the cantilevered end of the joists.

<tr>
<td>Footings</td>
<td>14” x 14” x 6”</td>
<td>18” x 18” x 6”</td>
</tr>
</tbody>
</table>

Conclusions:

For these two case studies, the biggest impacts are to ledger bolt spacing and footing sizes. Other differences are nominal, and in a few cases, no change in structure is required.

Another way to look at cost impacts is to compare what would be allowed for the various components — allowable beam and joist spans, required ledger connection spacing, allowable post heights, and required footing sizes. Based on the IRC and proposed tables by others:

Maximum Joist Spans:

To get the same maximize joist spans as allowed for 40 psf live loads, in general, the increased live load would require either one joist size larger, or one step tighter spacing. For example, a 2x8 HF joist is allowed...
to span 9'-1" at 24" o.c. when loaded at 40 psf. For 60 psf, the joists would need to be upsized to a 2x10 at 24" o.c., or 2x8s at 16" o.c. could be used. Note that tighter spacing may already be required for allowable deck board spans.

**Maximum Beam Spans:**

In general, at 60 psf, larger beam depths or more members will be required to achieve the same spans as for 40 psf loads. For example, a beam needed to span 8' between supports and supporting the 9'-1 span allowed for 2x8 HF joists at 40 psf would need to be a 3-2x10. A 3-2x12 would be required at 60 psf.

**Ledger Bolt Spacing**

Given the table structure, there’s not much that can be done to match ledger bolt spacing between 40 and 60 psf loads. The only way to match them is to reduce joist spans or sheathing thickness under 60 psf loads, neither of which is practical.

**Allowable Post Heights**

To achieve the same post heights for 40 psf when designing for 60 psf, in most cases, either post size must increase or tributary area must be decreased (=> add more posts). However, as post sizes get larger, fewer adjustments are needed. For example, a 4x4 HF post is allowed up to a 9’-3” height, at 40 psf with a tributary area of 80 square feet. At 60 psf, a 6x6 is required if the tributary remains the same, but 4x4s can still be used if the tributary area is halved. A 4x6 post with 60 square feet of tributary area will also work at 60 psf. Other combinations of post size increases and reduced tributary areas can be used.

**Footing Size**

Given the table structure, similar to posts, tributary areas must be reduced (=> more footings) in order for footings supporting 60 psf to be a similar size as those supporting 40 psf loads. The amount of reduction varies considerably, depending on the tributary area and the soil bearing allowable. For example, a footing supporting 60 square feet of tributary area at 40 psf load and 1500 psf bearing is required to be 17"x17"x6". At 60 psf live load, a 18"x18"x6" footing is required for 40 square feet of tributary area.

**Conclusions:**

If the desire is for a 60 psf live load design to maintain the maximum spans and heights for 40 psf live load, as well as the minimum footing sizes, member sizes or numbers of members will need to be increased. How much depends on the particulars of the design.

Proposal # 4343
RB51-19

IRC®: R301.6

Proponent: Stephanie Young, representing National Council of Structural Engineers Associations
(stephanie@mattsonmacdonald.com)

2018 International Residential Code

Revise as follows:

R301.6 Roof load. The roof shall be designed for the live load indicated in Table R301.6 or the ground snow load indicated in Table R301.2(1), whichever is greater.

Reason: Table R301.2(1) lists only a value for 'ground snow load', not 'snow load', nor does a method exist to make the conversion between the two values and to direct the user to the proper value.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The modified language is intended to coordinate the two sections.

Proposal # 4602
RB52-19

IRC®: TABLE R301.7

Proponent: Stephanie Young, representing National Council of Structural Engineers Associations
(stephanie@mattsonmacdonald.com)

2018 International Residential Code

Revise as follows:

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS

<table>
<thead>
<tr>
<th>STRUCTURAL MEMBER</th>
<th>ALLOWABLE DEFLECTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rafters having slopes greater than 3:12 with finished ceiling not attached to rafters</td>
<td>L/180</td>
</tr>
<tr>
<td>Interior walls and partitions</td>
<td>H/180</td>
</tr>
<tr>
<td>Floors</td>
<td>L/360</td>
</tr>
<tr>
<td>Ceilings with brittle finishes (including plaster and stucco)</td>
<td>L/360</td>
</tr>
<tr>
<td>Ceilings with flexible finishes (including gypsum board)</td>
<td>L/240</td>
</tr>
<tr>
<td>All other structural members</td>
<td>L/240</td>
</tr>
<tr>
<td>Exterior walls—wind loads with plaster or stucco finish</td>
<td>H/360</td>
</tr>
<tr>
<td>Exterior walls—wind loads with other brittle finishes</td>
<td>H/240</td>
</tr>
<tr>
<td>Exterior walls—wind loads with flexible finishes</td>
<td>H/120\textsuperscript{d}</td>
</tr>
<tr>
<td>Lintel supporting masonry veneer walls</td>
<td>L/600</td>
</tr>
</tbody>
</table>

Note: \( L \) = span length, \( H \) = span height.

a. For the purpose of the determining deflection limits herein, the wind load shall be permitted to be taken as 0.7 times the component and cladding (ASD) loads obtained from Table R301.2(2).
b. For cantilever members, \( L \) shall be taken as twice the length of the cantilever.
c. For aluminum structural members or panels used in roofs or walls of sunroom additions or patio covers, not supporting edge of glass or sandwich panels, the total load deflection shall not exceed \( L/60 \). For continuous aluminum structural members supporting edge of glass, the total load deflection shall not exceed \( L/175 \) for each glass lite or \( L/60 \) for the entire length of the member, whichever is more stringent. For sandwich panels used in roofs or walls of sunroom additions or patio covers, the total load deflection shall not exceed \( L/120 \).
d. Deflection for exterior walls with interior gypsum board finish shall be limited to an allowable deflection of \( H/180 \).
e. Refer to Section R703.8.2. Dead load of supported materials shall be included when calculating the deflection of these members.

Reason: The section which references this Table (Section R301.7) indicates that the Table contains the deflection limits when a member is subjected to live, snow, and/or wind loads. However, the section referenced by footnote ‘e’ (Section R703.8.2) notes that the weight of the material shall be considered in the design and limits the member deflection to \( L/600 \). The addition to the footnote simply clarifies the requirement in this specific case and eliminates conflicting information.
**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The modified language is only intended to clarify existing requirements.
2018 International Residential Code

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings, townhouses and accessory buildings shall comply with Table R302.1(1); or dwellings and townhouses equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of individual dwelling units and their accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling or townhouse located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

[RB] FIRE SEPARATION DISTANCE. The distance measured from the building face to one of the following:

1. To the closest interior lot line.
2. To the centerline of a street, an alley or public way.
3. To an imaginary line between two buildings or townhouses on the lot.

The distance shall be measured at a right angle from the face of the wall.

Reason: Prior to the 2015 IRC, Section R302.2 required each townhouse to be considered a separate building and be separated by fire-resistance-rated walls meeting requirements for exterior walls, with an exception to provide a fire-resistance-rated common wall. The 2015 IRC revised this section to only deal with common walls and a reference to exterior walls was removed. Since R302.1 only requires fire-resistance-rated exterior walls for dwellings and accessory buildings, all townhouse exterior wall requirements were essentially removed from the code since a townhouse does not meet the definition of a dwelling. Prior to 2015 IBC, an imaginary line would be established between each townhouse since they were considered separate buildings and fire separation distance would be measured to the imaginary line, and it is believed that most jurisdictions still enforce this way.

This proposal brings back the 2012 townhouse exterior wall requirements that are assumed to have been inadvertently removed from the code. It does this by adding townhouses to the scoping of R302.1 for exterior walls and by revising the definition of fire separation distance to include imaginary lines between townhouses (rather than calling townhouses separate buildings, which they are not). Townhouse exterior walls that are adjacent to lot lines would meet exterior wall requirements based on fire separation distance to the lot lines. Townhouse exterior walls that are adjacent to other townhouses, would meet exterior wall requirements based on fire separation distance to the imaginary line between two townhouses. See Figures 1 and 2 below for
application examples for this proposal. This proposal is necessary to fill the current hole in the code regarding exterior wall requirements for townhouses.

FIGURE 1 - IMAGINARY LINES BETWEEN TOWNHOUSES
FSD = FIRE SEPARATION DISTANCE

A = FSD FOR WALL G1
B = FSD FOR WALL G2
C = FSD = 0 FOR WALL H1
D = FSD FOR WALL H2
E = FSD FOR EXTENDING STORY WALL G3
F = FSD FOR EXTENDING STORY WALL G4
G = FSD FOR EXTENDING STORY WALL H3
H = FSD = 0 FOR WALL G5

FIGURE 2 - EXAMPLE FIRE SEPARATION DISTANCES
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal brings back previous code requirements that I believe are currently being enforced due to the lack of specific townhouse exterior wall requirements in the current code, so there should be no increase or decrease in the cost of construction.
2018 International Residential Code

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of individual dwelling units and their accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.
6. Walls of dwellings and accessory structures located on lots in subdivisions or zoning districts where building setbacks established by local ordinance prohibit the walls of the structures on adjacent lots from being closer than 10 feet (3048 mm) to each other at any point along the exterior walls.

Reason: It has become a routine process to issue building code modifications on a sub-division wide basis to allow dwellings on adjacent lots to be constructed without the fire-resistance rating required by R302 because the local zoning ordinance prohibits dwellings from being closer than 10 feet from each other. The zoning ordinance established set-backs effectively satisfy the intent of the code.

Cost Impact: The code change proposal will decrease the cost of construction. There is no cost impact for localities already allowing this through code modification. For localities not allowing through modification I would estimate $1000 to $5000 depending on the size and configuration of the wall required to be fire rated.

Proposal # 5608
2018 International Residential Code
Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2). For use of this Table, fire separation distance in the field shall be measured from the lot line to the foundation.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of individual dwelling units and their accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

TABLE R302.1(1)

</thead>
<tbody>
<tr>
<td>Unlimited</td>
<td>0 hours</td>
<td></td>
<td>5 feet</td>
</tr>
</tbody>
</table>

For SI: 1 foot = 304.8 mm.
NA = Not Applicable.

a. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave overhang if fireblocking is provided from the wall top plate to the underside of the roof sheathing.

b. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the rake overhang where gable vent openings are not installed.

c. Non rated exterior walls finishes shall not project more than 4 inches into the fire separation distance.

**Reason:** Footnote (c) allows for non-rated exterior wall finishes to project not more than 4 inches into the fire separation distance. Chapter 2 – Defines exterior wall covers as “A material or assembly of materials applied on the exterior side of exterior walls for the purpose of providing a weather-resistant barrier, insulation or for aesthetics, including but not limited to, veneers, siding, exterior insulation and finish systems, architectural trim and embellishments such as cornices, soffits, and fascias.”

Chapter 2 defines “fire separation distance” and requires the measurements to be taken from the lot line to the building face. For use of this table, field measurements shall be taken from the lot line to the foundation and not the building face.

This proposed amendment changes Table 302.1 (1) to provide a specific dimension to building face in footnote (c).

This proposed amendment will allow builders who have parcels with 5 foot building setbacks to the property line to construct buildings without the requirement for fire-resistant construction.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code proposal does not increase or decrease the cost of construction. It only provides clarity on the intent of the code language.
Proponent: David Renn, PE, SE, City and County of Denver, representing City and County of Denver
david.renn@denvergov.org

2018 International Residential Code
Revise as follows:

R302.2.2 Common walls. Common walls separating townhouses shall be assigned a fire-resistance rating in accordance with Item 1 or 2 and shall be rated for fire exposure from both sides. Common walls shall extend to and be tight against the exterior sheathing of the exterior walls, or the inside face of exterior walls without stud cavities, and the underside of the roof sheathing. The common wall shared by two townhouses shall be constructed without plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be in accordance with Chapters 34 through 43. Penetrations of the membrane of common walls for electrical outlet boxes shall be in accordance with Section R302.4.

1. Where a fire sprinkler system in accordance with Section P2904 is provided, the common wall shall be not less than a 1-hour fire-resistance-rated wall assembly tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code.

2. Where a fire sprinkler system in accordance with Section P2904 is not provided, the common wall shall be not less than a 2-hour fire-resistance-rated wall assembly tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code.

Exception: Common walls are permitted to extend to and be tight against the inside of the exterior walls if the cavity between the end of the common wall and the exterior sheathing is filled with a minimum of two two-inch nominal thickness wood studs.

Reason: The code currently allows a townhouse common wall to stop at the interior face of the exterior wall, which can create a path for a fire to spread from one townhouse to the next through the exterior wall. A typical common wall construction is two layers of gypsum board in metal H-studs that are connected to stud walls on either side for stability only, with a gap between the gypsum board and the stud walls. With the gap in this configuration, there is a path a fire can take that is only protected by two layers of 1/2" non-classified gypsum board (or other sheathing) - one on the stud wall adjacent to the common wall on the fire side and one on the same wall of the adjacent townhouse. Two layers of 1/2" gypsum board only provides approximately 30 minutes of fire protection until a fire can spread to the next townhouse. See figure below for clarification of this type of common wall construction.

This proposal requires common walls to continue to the exterior sheathing of the exterior wall, which will eliminate the path of fire described above and will provide the intended fire rating duration of the common wall. For solid exterior walls, such as concrete or masonry, this proposal allows common walls to stop at the inside face since a path for fire to spread from townhouse to townhouse doesn't exist in a solid exterior wall. The exception allows (2) 2x wood studs to be used to extend the common wall through the exterior wall stud cavity. Typical wood studs have a char rate of approximately 1.5" per hour, so this provides the required fire-resistance rating of the common wall.
**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The common wall extent requirement in this proposal is the typical way common walls are constructed, so there should be no change in construction or cost of construction.

Proposal # 4297

RB56-19
RB57-19
IRC®: R302.2

Proponent: Jeffrey Shapiro, P.E., representing Self (jeff.shapiro@intlcodeconsultants.com)

2018 International Residential Code

Revise as follows:

R302.2 Townhouses. Walls separating townhouse units shall be constructed in accordance with Section R302.2.1 or R302.2.2, and shall comply with Sections 302.2.3 through 302.2.5.

Reason: Sections 302.2.3 through 302.2.5 also apply to townhouse wall construction. It is appropriate for these sections to be referenced by the introductory section on townhouses, which is focused on townhouse walls.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Clarifies existing requirements.

</table>

For SI: 1 foot = 304.8 mm.

NA = Not Applicable.

- a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler system installed in accordance with Section P2904, the fire separation distance for exterior walls not fire-resistance rated and for fire-resistance-rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.

- b. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave overhang if fireblocking is provided from the wall top plate to the underside of the roof sheathing.

- c. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the rake overhang where gable vent openings are not installed in the overhang or in any gable end walls that are common to attic areas.

**Reason:** Staff continues to get questions regarding these footnotes. The existing language remains unclear, despite recent attempts to fix it. Ray Allshouse, the proponent of the code change that brought this language into the code, was contacted. He indicated that the intent was that if there were no vents at the underside of the overhang, or in any gable end walls (both of which would allow fire to freely move into attic areas), then there should be no requirement to rate the underside of the overhang. Mr. Allshouse also indicated that this concept could be applied gable, hip and any other roof style with overhangs. Where additional attic ventilation is required to make up for the loss of vents at overhangs where fire-separation distance is an issue in accordance these tables and footnotes, additional vents could be added at the underside of eaves in other areas of the dwelling.
where the fire-separation distance is not an issue, or at roof ridges.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/building-code-action-committee-bcac/.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change is a clarification of current code requirements.
2018 International Residential Code

Add new text as follows:

R302.2.3.1 Occupied Roof Rated Separation. Townhome separation, where the roof is intended to be occupied, shall continue the common wall between units to a height of 8 feet above the walking surface with a minimum one hour fire-resistance-rated wall assembly tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code and shall have noncombustible faces for the uppermost 18 inches (457 mm), including counterflushing and coping materials.

Reason: Occupied roofs are a new building element that has the potential to cause connected townhomes to be at a significant risk of fire hazard. In reviewing plans and looking at the current code requirements, the potential for risk of fire conflagration to involve connected townhome units does not seem to be addressed by the 2018 IRC. Fire data from the NFPA related to fires caused by gas grills alone would suggest that not having some protection to connected units leaves the occupants at risk. People will have the gas grills, charcoal grills and other fire related uses to occur on the occupied roofs. Even when fire sprinklers are installed the potential fire propagation from one unit to another is not addressed. Loss of life or even just losing the use of a home after a fire is significant. This proposal would help increase the chance that the fire would not involve connected units and allow the fire department response to contain the fire on the original unit.

NFPA Report fact sheet U.S. Home Fires Involving Grills

From 2011–2015, U.S. fire departments responded to an average of 9,600 home fires involving grills, hibachis, or barbecues per year. That number included an average of 4,100 structure fires and 5,500 outside or unclassified fires. These 9,600 fires caused annual averages of 10 civilian deaths, 160 reported civilian injuries, and $133 million in direct property damage.

Almost all the losses resulted from structure fires.

July (17%) was the peak month for grill fires, followed by May (14%), June (14%), and August (13%). Three percent of the fires occurred in each of the winter months of December, January, and February.

Causes of Grill Fires

Gas vs. Solid-Fuel Grills
Five out of six (82%) grills involved in home fires were fueled by gas, while 14% used charcoal or other solid fuel.
Gas grills were involved in an average of 7,900 home fires per year, including 3,300 structure fires and 4,700 outdoor fires annually. Leaks or breaks were primarily a problem with gas grills. Twelve percent of gas grill structure fires and 24% of outside gas grill fires were caused by leaks or breaks.
Charcoal or other solid-fuel grills were involved in 1,300 home fires per year, including 600 structure fires and 700 outside fires annually.

Fire and Non-Fire Emergency Room Visits Due to Grills
From 2012–2016, an average of 16,600 patients per year went to emergency rooms because of injuries...
involving grills.2
Half (8,200 or 49%) of the injuries were thermal burns, including burns both from fire and from contact with hot objects.
About 4,500 of the thermal burns were caused by such contact or other non-fire events.
Children under age 5 accounted for an average of 1,600 or one-third (35%) of the contact-type burns. The burns typically occurred when someone, often a child, bumped into, touched, or fell on the grill, grill part, or hot coals. Keep children away from the grill.

Cost Impact: The code change proposal will increase the cost of construction
The cost of construction will be increased but the amount is not static because it is based on the variables of the finishes and type of construction.
2018 International Residential Code

Revise as follows:

R302.2.6 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit fastened to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common wall as provided in Section R302.2.2, Item 1 or 2.
6. Townhouses protected by a fire sprinkler system complying with Section P2904 or NFPA 13D.

Reason: The IBC now allows townhouses to be built without structural independence provided that height and area limits for the overall townhouse building are not exceeded. This is true because the firewall requirement to separate units is no longer applicable in such cases. Therefore, only the 1-hour dwelling unit requirement applies, and that assembly is a fire barrier, which has no structural independence requirement. For reference IBC Section 706.1.1, Exception 2 states:

Fire walls are not required on lot lines dividing a building for ownership purposes where the aggregate height and area of the portions of the building located on both sides of the lot line do not exceed the maximum height and area requirements of this code. For the code official’s review and approval, he or she shall be provided with copies of dedicated access easements and contractual agreements that permit the owners of portions of the building located on either side of the lot line access to the other side for purposes of maintaining fire and life safety systems necessary for the operation of the building.

It makes no sense for the IRC to be more restrictive than the IBC with respect to requiring structural independence when townhouses are sprinklered.

Disclosure: although I am a consultant to the National Fire Sprinkler Association, this proposal is submitted on my own behalf and was not reviewed or endorsed by NFSA prior to submittal.

Cost Impact: The code change proposal will decrease the cost of construction. Construction costs are reduced, consistent with the IBC, based on the allowance to not require structural independence of townhouse units.
2018 International Residential Code

Revise as follows:

R302.2.6 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit fastened to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common wall as provided in Section R302.2.2, Item 1 or 2.

Reason: The current Exception 2 is for sheathing fastened to common wall framing, which is not necessary since Exception 5 completely exempts townhouses separated by a common wall. In other words, if the townhouse is exempt, the sheathing is also exempt, so Exception 2 is not needed.

Note that there is another proposal to revise Exception 5 to only apply to structural common walls. If this proposal is approved, the deletion of Exception 2 is still valid since there is no reason to fasten sheathing to a nonstructural common wall. For this condition, there will be structural framing adjacent to the non-structural common wall to fasten the sheathing to.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This proposal is simply a deletion of a non-relevant exception, so there should be no change to the cost of construction.

Proposal # 5655
2018 International Residential Code

Proponent: David Renn, PE, SE, City and County of Denver, representing Code Change Committee of Colorado Chapter of ICC (david.renn@denvergov.org)

Revise as follows:

R302.2.6 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit fastened to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a structural common wall as provided in Section R302.2.2, Item 1 or 2.

Reason: A regularly used townhouse common wall consists of two layers of 1" thick gypsum panels installed between steel H-studs and these H-studs are connected to stud walls of each townhouse for stability only - the fire-resistance rating is achieved entirely by the two layers of gypsum panels between steel H-studs. This type of common wall is a non-structural wall and for this condition there is no reason to exempt the townhouses from structural independence since floor and roof framing are supported on separate stud walls within each unit.

Cost Impact: The code change proposal will increase the cost of construction. This proposal typically will not change the cost of construction since it clarifies a condition that provides structural independence without cost. However, if the current exemption is used to share lateral loads (wind and seismic) between townhouses, a slight increase in cost may be realized since separate lateral systems will be required for each townhouse.

</tr>
</tbody>
</table>

For SI: 1 foot = 304.8 mm.

NA = Not Applicable.

a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler system installed in accordance with Section P2904, the fire separation distance for exterior walls not fire-resistance rated and for fire-resistance-rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.

b. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave overhang if fireblocking is provided from the wall top plate to the underside of the roof sheathing.

c. The fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the rake overhang where gable vent openings are not installed.

d. Applies to soffits constructed outside of exterior doors, including garage doors. Applies to the soffit area over doors and extending 3 feet horizontally in both directions from the vertical edges of doors.

**Add new text as follows:**
302.2.6 Protected Soffit. Soffit projections above exterior doors shall be 1-hour fire-resistance-rated on the soffit underside or constructed in accordance with Section R302.2.6.1.

302.2.6.1 Prescriptive Vented Protected Soffit. Soffits shall be constructed in accordance with one of the following:

1. Fasten one layer of Type X 5/8” gypsum panel attached to the underside of bottom of truss bottom chord or soffit framing member. Bottom panel shall have a venting space not more than 4” from the fascia board.
2. Fasten one layer of Type X 5/8” gypsum panel to the top of truss bottom chord or soffit framing member. Top panel shall have venting space not more than 4” from the top plate of the wall.

Ventilation cut into panels should not align vertically. Ventilation space shall have mesh applied with both panels in accordance with Section R806.1.

Reason: Recent trends in smoker habits have led to fires starting on the outside of homes and residences. Smokers are now discarding their cigarettes outside of entrances and into combustible mulch or trash cans with combustible materials in them. This change would provide an added protection in these areas where the fire risk has been identified.

There has been concern that by creating this fire block, ventilation at the soffit could become an issue. In exploratory testing by the Suburban Exterior Fire Work Group, it was found that by creating a chamber at the soffit, the assembly still provides ventilation but also creates an environment that slows down the movement of the fire due to lack of oxygen.

Here are photos of the test assemblies:
As proposed a 1 hour rated assembly can be used and ventilation would be found in other areas of the roof assembly or a prescriptive vented protected soffit could be constructed. Below is a abstract sketch of a profile of this assembly.
Cost Impact: The code change proposal will increase the cost of construction. This change will add labor and material costs associated with the added protection gypsum panels, fasteners, and mesh.
RB64-19

IRC®: R302.3, NFPA Chapter 44

Proponent: Jeffrey Shapiro, P.E., International Code Consultants, representing Self
(jeff.shapiro@intlcodeconsultants.com)

2018 International Residential Code

Revise as follows:

R302.3 Two-family dwellings. Dwelling units in two-family dwellings shall be separated from each other by wall and floor assemblies having not less than a 1-hour fire-resistance rating where tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code. Fire-resistance-rated floor/ceiling and wall assemblies shall extend to and be tight against the exterior wall, and wall assemblies shall extend from the foundation to the underside of the roof sheathing.

Exceptions:

1. A fire-resistance rating of $\frac{1}{2}$ hour shall be permitted in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 or NFPA 13-13D.
2. Wall assemblies need not extend through attic spaces where the ceiling is protected by not less than $\frac{5}{8}$-inch (15.9 mm) Type X gypsum board, an attic draft stop constructed as specified in Section R302.12.1 is provided above and along the wall assembly separating the dwellings and the structural framing supporting the ceiling is protected by not less than $\frac{1}{2}$-inch (12.7 mm) gypsum board or equivalent.

Reason: The current exception will never be used because the cost of installing a full NFPA 13 system (typically associated with commercial structures) in a duplex will far outweigh savings associated with reducing the separation wall rating from one-hour to 30 minutes. From a parity perspective, it makes no sense to allow Section P2904 or NFPA 13D protection as a basis for reducing townhouse separations but require NFPA 13 for duplexes.

Perhaps the logic associated with the current provision was intending to gain sprinkler protection in the attic (which would typically be required by NFPA 13) as a basis of qualifying for the reduced fire rating. But, townhouse separations are allowed to be reduced in unsprinklered attics of sprinklered townhouses, recognizing that the vast majority of residential fires start in occupied spaces, where sprinklers are present to control a fire before extension into the attic. True, a reduced townhouse separation maintains a one-hour rating, versus 30 minutes in a duplex, but 30 minutes is still a sufficient separation rating to accommodate fire department response and setup at a duplex.

Note that IRC Section R313 only requires NFPA 13D for duplexes, so this change will align with Section R313. Also, the reference to NFPA 13 is proposed for deletion since this is the only place in the IRC where that standard is referenced.

Disclosure: although I am a consultant to the National Fire Sprinkler Association, this proposal is submitted on
my own behalf and was not reviewed or endorsed by NFSA prior to submittal.

**Cost Impact:** The code change proposal will decrease the cost of construction
The change allows a reduction from NFPA 13 to NFPA 13D for duplex separation wall rating reduction.

2018 International Residential Code

Revise as follows:

R302.3 Two-family dwellings. Dwelling units in two-family dwellings shall extend from foundation to roof, shall have a yard or public way on not less than three sides, and shall be separated from each other by wall and floor assemblies having not less than a 1-hour fire-resistance rating where tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code. Fire-resistance-rated floor/ceiling and wall assemblies shall extend to and be tight against the exterior wall, and wall assemblies shall extend from the foundation to the underside of the roof sheathing.

Exceptions:

1. A fire-resistance rating of 1/2 hour shall be permitted in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 or NFPA 13-13D.

2. Wall assemblies need not extend through attic spaces where the ceiling is protected by not less than 5/8-inch (15.9 mm) Type X gypsum board, an attic draft stop constructed as specified in Section R302.12.1 is provided above and along the wall assembly separating the dwellings and the structural framing supporting the ceiling is protected by not less than 1/2-inch (12.7 mm) gypsum board or equivalent.

3. Dwelling units in two-family dwellings shall be permitted to be stacked vertically where both dwelling units are equipped with an automatic sprinkler system installed in accordance with Section P2904 or NFPA 13D. The floor/ceiling assembly separating the dwelling units shall be permitted to have a fire-resistance rating of 1/2 hour where tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code.

Reason: Stacked duplexes are much more hazardous than side-by-side duplexes for several reasons. An upstairs unit is significantly more dangerous because smoke, heat and flames from a fire in the first-floor unit will attempt to travel vertically into the upstairs unit. Smoke alarms are not interconnected between duplex units and there is no fire alarm. So the upstairs occupant warning will be delayed until a fire in the lower has grown significantly, particularly if the downstairs unit occupant is not home or is home but doesn’t or is unable to warn the upstairs unit occupant.

The IRC does not require the floor/ceiling fire separation to be a smoke barrier, so once the fire is large enough, the upstairs unit will flood with smoke. The smoke alarm in the upstairs unit may not provide adequate warning time for escape because smoke alarms are designed to provide escape from fires detected in incipient stages, not well-developed fires. Further, the IRC does not provide a rated enclosure for egress from the upper unit, so the means of egress might go directly through the rated floor/ceiling assembly and directly into the fire and smoke below. Even an outside stair is of questionable adequacy because windows and doors are often stacked vertically. Once a fire breaks out of the lower unit, upper unit escape windows and stairs can be quickly compromised.

The prevalence of stacked duplexes is increasing in some areas, and the associated fire risk is being amplified by the fact that such units can be two stories with an additional story and an occupied attic above (essentially a 4 story structure). This begs the question of why townhouses aren't allowed to include stacked units. The answer is that such designs become multifamily occupancies and are required to be constructed in accordance
with the IBC in response to the increased fire risk.

It isn't feasible to expect that a duplex could be built with a fire-resistive means of egress for upstairs units, a smoke-rated floor ceiling assembly and opening protectives and listed penetration smoke seals and fire stops to protect the upstairs unit, so this proposal recommends that fire sprinklers be specifically provided for stacked duplex buildings.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Technically, the IRC requires all buildings to be sprinklered, so this doesn't have a cost impact with respect to the model code. However, in jurisdictions that choose to amend the IRC by removing the sprinkler requirement, there would be a cost increase.
**2018 International Residential Code**

**Revise as follows:**

**R302.3 Two-family dwellings.** *Dwelling units* in two-family dwellings shall be separated from each other by wall and floor assemblies having not less than a 1-hour fire-resistance rating where tested in accordance with ASTM E119, UL 263 or Section 703.3 of the International Building Code. *Such separation shall be provided regardless* of whether a lot line exists between the two dwelling units or not. Fire-resistance-rated floor/ceiling and wall assemblies shall extend to and be tight against the *exterior wall*, and wall assemblies shall extend from the foundation to the underside of the roof sheathing.

**Exceptions:**

1. A fire-resistance rating of $\frac{1}{2}$ hour shall be permitted in buildings equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13.

2. Wall assemblies need not extend through *attic* spaces where the ceiling is protected by not less than $\frac{5}{8}$-inch (15.9 mm) Type X gypsum board, an *attic* draft stop constructed as specified in Section R302.12.1 is provided above and along the wall assembly separating the *dwellings* and the structural framing supporting the ceiling is protected by not less than $\frac{1}{2}$-inch (12.7 mm) gypsum board or equivalent.

**Reason:** The intent of this proposal is to clarify the separation between the dwelling units in a two-family dwelling. A proposal (RB52-16) was submitted last cycle that required two 1-hour walls between the units if a lot line existed and a single wall if a lot line was not present. The committee disapproved the change because they felt that the revised language complicated the existing requirements in the code. The proposal intends to simplify the requirements. The presence of a lot line between the dwelling units does not change the impact of fire spread from one unit to another. The fire does not know whether there is a lot line there or not. This issue has been raised for many years. That indicates that there is a serious problem with this requirement. The proposal clearly indicates that the one-hour separation is required regardless of the presence of a lot line. Many people, including the commentary, state that if there is a lot line between the two units, that two 1-hour walls are required. I challenge anyone to show me where in Section 302.3 it states that. This section only requires a single 1-hour wall. There is also no requirement that states that the two units are separate buildings similar to what we used to do with townhouses. So, the application of Section 302.1 is not referenced in this section. The definition of dwelling states that it is any building that contains one or two dwelling units... It is a single building, not two separate buildings as some would like to say.

**Cost Impact:** The code change proposal will decrease the cost of construction

Since many jurisdictions are requiring two 1-hour walls when a lot line is present, the cost of the separation will be reduced with this change.
2018 International Residential Code

Revise as follows:

R302.4.1 Through penetrations. Through penetrations of fire-resistance-rated wall or floor assemblies shall comply with Section R302.4.1.1 or R302.4.1.2.

**Exception:** Where the penetrating items are steel, ferrous or copper pipes, tubes or conduits, or listed fire sprinkler piping, the annular space shall be protected as follows:

1. In concrete or masonry wall or floor assemblies, concrete, grout or mortar shall be permitted where installed to the full thickness of the wall or floor assembly or the thickness required to maintain the fire-resistance rating, provided that both of the following are complied with:
   1.1. The nominal diameter of the penetrating item is not more than 6 inches (152 mm).
   1.2. The area of the opening through the wall does not exceed 144 square inches (92900 mm²).
2. The material used to fill the annular space shall prevent the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E119 or UL 263 time temperature fire conditions under a positive pressure differential of not less than 0.01 inch of water (3 Pa) at the location of the penetration for the time period equivalent to the fire-resistance rating of the construction penetrated.

**Reason:** Listed fire sprinkler piping is ignition resistant and will not sustain combustion. Allowing common fire sprinkler piping to protect multiple units in a townhouse can significantly reduce installation costs, and the IBC now allows penetration of townhouse separation walls in any townhouse that does not exceed the height and area limits. For reference IBC Section 706.1.1, Exception 2 states:

*Fire walls are not required on lot lines dividing a building for ownership purposes where the aggregate height and area of the portions of the building located on both sides of the lot line do not exceed the maximum height and area requirements of this code. For the code official's review and approval, he or she shall be provided with copies of dedicated access easements and contractual agreements that permit the owners of portions of the building located on either side of the lot line access to the other side for purposes of maintaining fire and life safety systems necessary for the operation of the building.*

It makes no sense for the IRC to be more restrictive than the IBC with respect to allowing penetration of sprinkler piping through townhouse separation walls.

Disclosure: although I am a consultant to the National Fire Sprinkler Association, this proposal is submitted on my own behalf and was not reviewed or endorsed by NFSA prior to submittal.

**Cost Impact:** The code change proposal will decrease the cost of construction. The allowance for sprinkler piping to penetrate townhouse separation walls will reduce the infrastructure required to install a fire sprinkler system in some cases by allowing a shared feed for multiple units.
SECTION R302
FIRE-RESISTANT CONSTRUCTION

Revise as follows:

R302.5 Dwelling-garage and Dwelling-Energy Storage System Room opening and penetration protection. Openings and penetrations through the walls or ceilings separating the dwelling from the garage or from rooms containing energy storage systems, shall be in accordance with Sections R302.5.1 through R302.5.3.

R302.5.1 Opening protection. Openings from a private garage or a room containing an energy storage system(s), directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence, and between an energy storage system room and residence, shall be equipped with solid wood doors not less than 1 1/8 inches (35 mm) in thickness, solid or honeycomb-core steel doors not less than 1 1/8 inches (35 mm) thick, or 20-minute fire-rated doors, equipped with a self-closing or automatic-closing device.

R302.5.2 Duct penetration. Ducts in the garage and ducts penetrating the walls or ceilings separating the dwelling from the garage shall be constructed of a minimum No. 26 gage (0.48 mm) sheet steel or other approved material and shall not have openings into the garage.

TABLE R302.6
DWELLING-GARAGE AND DWELLING-Energy STORAGE SYSTEM (ESS) ROOM, SEPARATION

<table>
<thead>
<tr>
<th>SEPARATION</th>
<th>MATERIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the residence and attics</td>
<td>Not less than 1/2-inch gypsum board or equivalent applied to the garage side or energy storage system room side</td>
</tr>
<tr>
<td>From habitable rooms above the garage or an energy storage system room</td>
<td>Not less than 5/8-inch Type X gypsum board or equivalent</td>
</tr>
<tr>
<td>Structure(s) supporting floor/ceiling assemblies used for separation required by this section</td>
<td>Not less than 1/2-inch gypsum board or equivalent</td>
</tr>
<tr>
<td>Garages or energy storage system buildings located less than 3 feet from a dwelling unit on the same lot</td>
<td>Not less than 1/2-inch gypsum board or equivalent applied to the interior side of exterior walls that are within this area</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Reason: The evolution of battery technologies is moving faster than the building codes. This code change provides a reasonable amount of protection for energy storage in residential structures, by utilizing the existing separation requirements already in the code in section R302.5.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The code currently requires this separation for garages; this code change just directs you to place energy
storage systems within that space or a space equally protected.
2018 International Residential Code

Revise as follows:

R302.5.1 Opening protection. Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence shall be equipped with solid wood doors not less than 1 3/8 inches (35 mm) in thickness, solid or honeycomb-core steel doors not less than 1 3/8 inches (35 mm) thick, or 20-minute fire-rated doors, equipped with a self-closing or automatic-closing device and self-latching device.

Reason: In order for the door between the garage and residence to properly prevent the passage of smoke, fire, and carbon monoxide, the door must be latched. Self-latching is just as important as self-closing. If the door does not latch in the closed position, it is not properly secured. Air pressures caused by a fire could cause doors without a self-latching device to open. Some door knobs and handles enable self-latching by design and proper installation, thus the provision is often taken for granted, but this is not necessarily true of all installations. The language of this proposal would prevent the installation of a push/pull knob without latching.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. If the intent of the code is for the garage door to be safely closed, then self-latching has already been part of the provision, though not clearly stated. Therefore, placing the language in the code will simply make it clearer and does not affect the cost of construction.
2018 International Residential Code

Revise as follows:

R302.8 Foam plastics. For requirements for foam plastics, see Foam plastics shall not be used as interior finish materials except as permitted by Section R316.

Reason: It is important to clarify that foam plastics shall not be used as interior finish materials unless they meet the requirements of section R316. The existing code language just sends the code user to R316 but does not specifically state that foam plastic products are not to be used as interior finish materials unless they meet the appropriate requirements, based on testing to NFPA 286 (which typical foam plastics do not meet) or are covered by a thermal barrier. Experience indicates that it is not safe to have exposed foam plastics that have been tested only to ASTM E84.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is simple clarification.
Add new text as follows:

**R302.9.4 High density polyethylene (HDPE) and polypropylene (PP).** Where high density polyethylene or polypropylene is used as an interior finish material, it shall be tested in accordance with NFPA 286 and comply with the requirements in Section R302.9.4.

**Reason:** This proposal brings in a key fire safety requirement from the IBC and the IFC. The new section addresses the issue that it is not appropriate to allow testing of high density polyethylene (HDPE) and polypropylene (PP) materials used as interior finish in accordance with ASTM E84 or UL 723, because the test results are misleading. Such materials must be tested to NFPA 286, as shown in the existing section R302.9.4. A proposal that reorganizes the section on testing of interior finish places the requirements for NFPA 286 into section R302.9.1.1.

**Cost Impact:** The code change proposal will increase the cost of construction. It is unsafe to test HDPE and PP materials for use as interior finish with ASTM E84 or UL 723.
2018 International Residential Code

Delete without substitution:

*R302.9 Flame spread index and smoke-developed index for wall and ceiling finishes.* Flame spread and smoke-developed indices for wall and ceiling finishes shall be in accordance with Sections R302.9.1 through R302.9.4.

*R302.9.1 Flame spread index.* Wall and ceiling finishes shall have a flame spread index of not greater than 200.

**Exception:** Flame spread index requirements for finishes shall not apply to trim defined as picture molds, chair rails, baseboards and handrails; to doors and windows or their frames; or to materials that are less than \(\frac{3}{4}\) inch (0.91 mm) in thickness cemented to the surface of walls or ceilings if these materials exhibit flame spread index values not greater than those of paper of this thickness cemented to a noncombustible backing.

*R302.9.2 Smoke-developed index.* Wall and ceiling finishes shall have a smoke-developed index of not greater than 450.

*R302.9.3 Testing.* Tests shall be made in accordance with ASTM E84 or UL 723.

*R302.9.4 Alternative test method.* As an alternative to having a flame spread index of not greater than 200 and a smoke-developed index of not greater than 450 where tested in accordance with ASTM E84 or UL 723, wall and ceiling finishes shall be permitted to be tested in accordance with NFPA 286. Materials tested in accordance with NFPA 286 shall meet the following criteria:

The interior finish shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
3. Flashover, as defined in NFPA 286, shall not occur.
4. The peak heat release rate throughout the test shall not exceed 800 kW.
5. The total smoke released throughout the test shall not exceed 1,000 m².

Add new text as follows:

*R302.9 Interior wall and ceiling finishes.* Interior wall and ceiling finish materials shall be classified for fire performance and smoke development in accordance with Section R302.9.1 or R302.9.2, unless otherwise shown in Sections R302.9.3 through R302.9.9. Materials tested in accordance with Section R302.9.1 shall not be required to be tested in accordance with Section R302.9.2.

*R302.9.1 NFPA 286.* Interior wall and ceiling finish materials shall be classified in accordance with NFPA 286 and comply with Section R302.9.1.1. Materials complying with Section R302.9.1.1 shall be considered to also comply with the requirements of Section R302.9.2.
R302.9.1.1 Acceptance criteria for NFPA 286. The interior finish shall comply with the following:
1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
3. Flashover, as defined in NFPA 286, shall not occur.
4. The peak heat release rate throughout the test shall not exceed 800 kW.
5. The total smoke released throughout the test shall not exceed 1,000 m².

R302.9.2 ASTM E84 or UL 723. Wall and ceiling finishes shall exhibit a flame spread index not exceeding 200 and a smoke-developed index not exceeding 450 (Class C) where tested in accordance with ASTM E84 or UL 723, except as shown in Section R302.9.1 and in Sections R302.9.3 through R302.9.9.

R302.9.3 Interior trim. The requirements of Section R302.9.1 and those of Section R302.9.2, for interior wall and ceiling finishes, shall not apply to interior trim, defined as picture molds, chair rails, baseboards and handrails; or to doors and windows or their frames.

R302.9.4 Thickness exemption. The requirements of Section R302.9.1 and those of Section R302.9.2, for interior wall and ceiling finishes, shall not apply to materials having a thickness less than 0.036 inch (0.9 mm) and applied directly to the surface of walls or ceilings.

R302.9.5 High density polyethylene and polypropylene. Where high density polyethylene or polypropylene is used as an interior finish material, it shall be tested in accordance with NFPA 286 and comply with the requirements of Section R302.9.1.1.

R302.9.6 Facings or wood veneers intended to be applied on site over a wood substrate. Facings or veneers intended to be applied on site over a wood substrate shall comply with one of the following:
1. The facing or veneer shall meet the criteria of Section R302.9.1.1 where tested in accordance with NFPA 286 using the product-mounting system, including adhesive, as described in Section 5.9 of NFPA 286.
2. The facing or veneer shall exhibit a Class C flame spread index and smoke-developed index where tested in accordance with ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2404.

R302.9.7 Laminated products factory-produced with a wood substrate. Laminated products factory-produced with a wood substrate shall comply with one of the following:
1. The laminated product shall meet the criteria of Section R309.2.1.1 where tested in accordance with NFPA 286 using the product-mounting system, including adhesive, as described in Section 5.8 of NFPA 286.
2. The laminated product shall have a Class C flame spread index and smoke-developed index where tested in accordance with ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2579.

R302.9.8 Textile or expanded vinyl wall covering materials. Where textile wall covering materials or expanded vinyl wall covering materials are used as interior finish materials they shall be tested for fire performance in accordance with Sections R302.9.8.1, R302.9.8.2 or R302.9.8.3.

R302.9.8.1 Testing of textile or expanded vinyl wall covering materials to NFPA 286. Textile wall covering materials or expanded vinyl wall covering materials shall be tested in the manner intended for use in accordance with NFPA 286 using the product-mounting system, including adhesive, and comply with the requirements of Section R302.9.1.1.

R302.9.8.2 Testing of textile or expanded vinyl wall covering materials to ASTM E84 or UL 723. Textile wall covering materials or expanded vinyl wall covering materials shall exhibit a flame spread index not exceeding 200 and a smoke-developed index not exceeding 450 (Class C) where tested in accordance with
R302.9.8.3 Testing of textile or expanded vinyl wall covering materials to NFPA 265. Textile wall covering materials and expanded vinyl wall covering materials shall be tested in the manner intended for use in accordance with the Method B protocol of NFPA 265 using the product-mounting system, including adhesive. The wall coverings shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremities of the samples on the 8-foot by 12-foot (203 by 305 mm) walls.
3. Flashover, as defined in NFPA 265, shall not occur.
4. The total smoke released throughout the test shall not exceed 1,000 m².

R302.9.9 Textile or expanded vinyl ceiling covering materials. Textile ceiling covering materials or expanded vinyl ceiling covering materials shall be fire tested in accordance with ASTM E84 or UL 723, with the acceptance criteria of Section R302.9.2, or in accordance with NFPA 286, with the acceptance criteria of Section R302.9.1.1. Where tested in accordance with ASTM E84 or UL 723, specimen preparation and mounting shall be in accordance with ASTM E2404.

Add new standard(s) as follows:

**ASTM**

E2404: Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics (2017)

**NFPA**

265: Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls (2019)

Reason: This proposal reorganizes the section in the way that it is organized also in the IBC and IFC without changing requirements. Any material can be fire tested to NFPA 286 and those requirements are placed first, in R302.9.2. With regard to the base requirement (testing for flame spread index and smoke-developed index by means of ASTM E84 or UL 723, with the corresponding criteria) it is still a Class C (flame spread index of 200 or less and smoke developed index of 450 or less) and it is all in a single section, namely R302.9.2. There is no change in the sense that, just like in the present code, materials can be tested to ASTM E84 or UL 723 (and get a Class C), or they can be tested to NFPA 286, with the requirements presently in the code.
The following sections address requirements for materials that require special consideration.

Sections R302.9.3 and R302.9.4 address the exceptions: for trim and for very thin materials, adhered directly to the wall or ceiling. The requirement that the very thin material be tested contradicts the point that it is an exception and that it does not need testing. This requirement for testing the very thin material has been eliminated from the IBC and IFC also.

Section R302.9.5 addresses a key fire safety issue: high density polyethylene (HDPE) and polypropylene (PP) materials used as interior finish should not be tested using ASTM E84 because the test results are misleading. Such materials must be tested to NFPA 286, as shown in R302.9.1. This is a fire safety requirement also contained in the IBC and the IFC. The new section addresses the issue that it is not appropriate to allow testing of high density polyethylene (HDPE) and polypropylene (PP) materials used as interior finish in accordance with ASTM E84 or UL 723, because the test results are misleading. Such materials must be tested to NFPA 286, as shown in the new section R302.9.1.

What is needed is some testing requirement for thin materials used as veneers but adhered to wood products, either as manufactured panels brought into the building or as veneers applied on site. They are being addressed in R302.9.6 and R302.9.7. It has been shown that applying veneers over a wood product will have a significant effect (typically negative) on the fire performance of the product. A specific mounting practice for this has been developed both for ASTM E84 (namely ASTM E2404) and a specific section of NFPA 286 was developed for the purpose also. When a veneer is installed on site over a wood substrate, details are needed for fire testing the veneer. It needs to be tested over a substrate that is consistent with the substrate to be used in the application. If the veneer is to be applied over wood it should be tested over wood but if it is to be applied over gypsum board or a noncombustible substrate, it should be tested over that substrate. If the substrate is combustible testing over a wood substrate is an acceptable alternative. Section R302.9.7 addresses the case when manufacturers produce wood panels that have the veneer already applied before being introduced into the building. For that case, a specific mounting practice for ASTM E84 and a specific mounting method for NFPA 286 have been developed. In both cases the requirements involve testing the commercial panel and not the veneer. This language in both sections is consistent with language in the IBC and IRC, except that the requirements are for a Class C in ASTM E84, consistent with the charging paragraph.

Textile wall covering materials and expanded vinyl wall covering materials (Section R302.9.8) are permitted by the IBC and the IFC to be fire tested by three methods (they are the only type of product that have that option). They can be tested to ASTM E84 or UL 723, NFPA 286 and NFPA 265. If they are tested to ASTM E84 or UL 723 they need to use a special mounting method, namely ASTM E2404. Both the IBC and the IFC recognize a specific testing method that applies only to textile wall covering materials and expanded vinyl covering materials, namely NFPA 265. Therefore, commercial materials exist that have been tested to NFPA 265 and there is no reason that they should not be allowed into the IRC without further testing. The proposal contains the criteria from the IBC and IFC for testing to NFPA 265. This proposal does not require the materials to be tested to NFPA 265 or to NFPA 286 but allows materials already tested to NFPA 265 or to NFPA 286 to be used in the IRC. The NFPA 265 test is a room-corner test similar to NFPA 286, except for a few aspects: (a) the burner flame is less severe (150 kW instead of 160 kW), (b) the location of the burner is different (it is not placed flush against the corner) and (c) the material is not placed on the ceiling. Therefore the burner flame never reaches the ceiling, which makes the test unsuitable for ceiling materials.

Textile ceiling covering materials and expanded vinyl ceiling covering materials (Section R302.9.9) are permitted by the IBC and the IFC to be tested to NFPA 286 or to be tested to ASTM E84 or UL 723. However, when they are tested to ASTM E84 they need to use a special mounting method, namely ASTM E2404. They are not permitted to be tested to NFPA 265 because the flame in the test does not reach the ceiling.

Cost Impact: The code change proposal will increase the cost of construction
This proposal provides more testing options for some materials and clarifies the testing requirements that apply to some materials that should not be tested to ASTM E84.

Staff Analysis: The referenced standards, ASTM E 2579, ASTM E 2404 and NFPA 265, are currently referenced in other 2018 I-codes.

Proposal # 4469
RB73-19
IRC®: R302.9.6 (New), ASTM Chapter 44 (New)

Proponent: Marcelo Hirschler, representing GBH International (mmh@gbhint.com)

2018 International Residential Code
Add new text as follows:

R302.9.6 Facings or wood veneers intended to be applied on site over a wood substrate. Facings or veneers intended to be applied on site over a wood substrate shall comply with one of the following:

1. The facing or veneer shall meet the criteria of Section R302.9.4 where tested in accordance with NFPA 286 using the product mounting system, including adhesive, as described in Section 5.9 of NFPA 286.
2. The facing or veneer shall exhibit a Class C flame spread index and smoke-developed index where tested in accordance with ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2404.

Add new standard(s) as follows:

ASTM

E2404-17: Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics

Reason: It has been shown that applying veneers over a wood product will have a significant effect (typically negative) on the fire performance of the product. A specific mounting practice for this has been developed both for ASTM E84 (namely ASTM E2404) and a specific section of NFPA 286 was developed for the purpose also. When a veneer is installed on site over a wood substrate, details are needed for fire testing the veneer. It needs to be tested over a substrate that is consistent with the substrate to be used in the application. If the veneer is to be applied over wood it should be tested over wood but if it is to be applied over gypsum board or a noncombustible substrate, it should be tested over that substrate. If the substrate is combustible testing over a wood substrate is an acceptable alternative.

An alternate proposal addresses the case when manufacturers produce wood panels that have the veneer already applied before being introduced into the building. For that case, a specific mounting practice for ASTM E84 and a specific mounting method for NFPA 286 have been developed. In both cases the requirements involve testing the commercial panel and not the veneer.

This language is consistent with language in the IBC and IRC, except that the requirements are for a Class C in ASTM E84, consistent with the charging paragraph.

This proposal refers to the existing section R302.9.4 but an alternate proposal reorganizes the section and makes that section into R302.9.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

ASTM E84 explains that this is the way that veneers to be applied on site are to be tested.

Staff Analysis: The referenced standard, ASTM E 2402, is currently referenced in other 2018 I-codes.
2018 International Residential Code

Add new text as follows:

R302.9.7 Laminated products factory produced with a wood substrate.
1. Laminated products factory produced with a wood substrate shall comply with one of the following: The laminated product shall meet the criteria of Section R309.2.4 where tested in accordance with NFPA 286 using the product-mounting system, including adhesive, as described in Section 5.8 of NFPA 286.
2. The laminated product shall have a Class C flame spread index and smoke-developed index where tested in accordance with ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2579.

Add new standard(s) as follows:

ASTM

E2579-15: Standard Practice for Specimen Preparation and Mounting of Wood Products to Assess Surface Burning Characteristics

Reason: It has been shown that applying veneers over a wood product will have a significant effect (typically negative) on the fire performance of the product. When manufacturers produce wood panels that have the veneer already applied before being introduced into the building, a specific mounting practice for ASTM E84 and a specific mounting method for NFPA 286 have been developed. In both cases the requirements involve testing the commercial panel and not the veneer. This language is consistent with language in the IBC and IRC, except that the requirements are for a Class C in ASTM E84, consistent with the charging paragraph.

An alternate proposal addresses veneers that are installed on site and not as part of factory produced panels.

This proposal refers to the existing section R302.9.4 but an alternate proposal reorganizes the section and makes that section into R302.9.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposed mounting method is the required one contained in ASTM E84.

Staff Analysis: The referenced standard, ASTM E 2579, is currently referenced in other 2018 I-codes.
**R302.9.8 Textile and expanded vinyl wall covering materials.** Where textile wall covering materials or expanded vinyl wall covering materials are used as interior finish materials they shall be tested for fire performance in accordance with Sections R302.9.8.1, R302.9.8.2 or R302.9.8.3.

**R302.9.8.1 NFPA 286.** Textile wall covering materials and expanded vinyl wall covering materials shall be tested in the manner intended for use in accordance with NFPA 286 using the product-mounting system, including adhesive, and comply with the requirements of Section R302.9.4.

**R302.9.8.2 ASTM E84 or UL 723.** Textile wall covering materials or expanded vinyl wall covering materials shall exhibit a flame spread index not exceeding 200 and a smoke-developed index not exceeding 450 (Class C) where tested in accordance with ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2404.

**R302.9.8.3 NFPA 265.** Textile wall covering materials and expanded vinyl wall covering materials shall be tested in the manner intended for use in accordance with the Method B protocol of NFPA 265 using the product-mounting system, including adhesive. The wall coverings shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremities of the samples on the 8-foot by 12-foot (203 by 305 mm) walls.
3. Flashover, as defined in NFPA 265, shall not occur.
4. The total smoke released throughout the test shall not exceed 1,000 m².

Add new standard(s) as follows:

**ASTM E2404:** Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics (2017)

**NFPA 265:** Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings on Full Height Panels and Walls (2019)

**Reason:** Textile wall covering materials and expanded vinyl wall covering materials are permitted by the IBC.
and the IFC to be fire tested by three methods (they are the only type of product that have that option). They can be tested to ASTM E84 or UL 723, NFPA 286 and NFPA 265. If they are tested to ASTM E84 or UL 723 they need to use a special mounting method, namely ASTM E2404. Both the IBC and the IFC recognize a specific testing method that applies only to textile wall covering materials and expanded vinyl covering materials, namely NFPA 265. Therefore, commercial materials exist that have been tested to NFPA 265 and there is no reason that they should not be allowed into the IRC without further testing. The proposal contains the criteria from the IBC and IFC for testing to NFPA 265.

This proposal does not require the materials to be tested to NFPA 265 or to NFPA 286 but allows materials already tested to NFPA 265 or to NFPA 286 to be used in the IRC.

The NFPA 265 test is a room-corner test similar to NFPA 286, except for a few aspects: (a) the burner flame is less severe (150 kW instead of 160 kW), (b) the location of the burner is different (it is not placed flush against the corner) and (c) the material is not placed on the ceiling. Therefore the burner flame never reaches the ceiling, which makes the test unsuitable for ceiling materials.

An alternate proposal reorganizes the section and renumbers section R302.9.4 as R302.9.1.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The methods proposed here are alternate options but do not affect testing in accordance with the present code. The mounting method for ASTM E84 is contained in the standard.

**Staff Analysis:** The referenced standards, ASTM E 2404-2017 and NFPA 265-2019, are currently referenced in other 2018 I-codes.

Proposal # 4476
2018 International Residential Code

Add new text as follows:

R302.9.9 Textile and expanded vinyl ceiling covering materials. Textile ceiling covering materials or expanded vinyl ceiling covering materials shall be fire tested in accordance with ASTM E84 or UL 723, with the acceptance criteria of Sections R302.9.1 and R302.9.2, or in accordance with NFPA 286, with the acceptance criteria of Section R302.9.4. Where tested in accordance with ASTM E84 or UL 723, specimen preparation and mounting shall be in accordance with ASTM E2404.

Add new standard(s) as follows:

ASTM

E2404: Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facing and Veneers to Assess Surface Burning Characteristics (2017)

Reason: Textile ceiling covering materials and expanded vinyl ceiling covering materials are permitted by the IBC and the IFC to be tested to NFPA 286 or to be tested to ASTM E84 or UL 723. However, when they are tested to ASTM E84 they need to use a special mounting method, namely ASTM E2404. They are not permitted to be tested to NFPA 265 because the flame in the test does not reach the ceiling. Note that this does not require testing to NFPA 286 but it is simply an option, especially for materials that have already been approved by testing that way. This is just being more explicit with regard to what is in the code.

An alternate proposal combines existing sections R302.9.1, R302.9.2 and R302.9.3 into a section R302.9.2 and also converts existing section R302.9.4 into section R302.9.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The revision makes the code more explicit without adding any requirements.

Staff Analysis: The referenced standard, ASTM E 2404-2017, is currently referenced in other 2018 I-codes.

Proposal # 4508
2018 International Residential Code

Add new text as follows:

R302.15 Fire retardant treated wood  Fire-retardant treated wood (FRTW) is any wood product that:

1. is impregnated with chemicals by a pressure process or other means during manufacture;
2. that has a listed flame spread index of 25 or less when tested in accordance with ASTM E84 or UL 723;
3. and that does not show evidence of significant progressive combustion when the test is continued for an additional 20-minute period. In addition, the flame front shall not progress more than 10.5 feet (3200 mm) beyond the center line of the burners at any time during the test.

R302.15.1 Pressure process  For wood products impregnated with chemicals by a pressure process, the process shall be performed in closed vessels under pressures not less than 50 pounds per square inch gauge (psig) (344.7 kPa).

R302.15.2 Other means during manufacture  For wood products produced by other means during manufacture, the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product.

R302.15.3 Testing  For wood products produced by means other than a pressure process during manufacture, all sides of the wood product shall be tested in accordance with and produce the results required in Section R302.15. For structural panels, only the front and back faces shall be required to be tested.

Revise as follows:

R802.1.5 Fire-retardant-treated wood.  Fire-retardant-treated wood (FRTW) is any wood product that, when impregnated with chemicals by a pressure process or other means during manufacture, shall have, when tested in accordance with ASTM E84 or UL 723, a listed flame spread index of 25 or less and does not show evidence of significant progressive combustion where the test is continued for an additional 20-minute period. In addition, the flame front shall not progress more than 10.5 feet (3200 mm) beyond the center line of the burners at any time during the test. Shall comply with Section R302.15.

Delete without substitution:

R802.1.5.1 Pressure process.  For wood products impregnated with chemicals by a pressure process, the process shall be performed in closed vessels under pressures not less than 50 pounds per square inch gauge (psig) (344.7 kPa).

R802.1.5.2 Other means during manufacture.  For wood products produced by other means during manufacture the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product.

R802.1.5.3 Testing.  For wood products produced by other means during manufacture, other than a pressure process, all sides of the wood product shall be tested in accordance with and produce the results required in Section R802.1.5. Testing of only the front and back faces of wood structural panels shall be permitted.

Revise as follows:
R802.1.5.4 Labeling. In addition to the labels required by Section 802.1.1 for sawn lumber and Section 803.2.1 for wood structural panels, each piece of fire-retardant-treated lumber and wood structural panel shall be labeled. The label shall contain:

1. The identification mark of an approved agency in accordance with Section 1703.5 of the International Building Code.
2. Identification of the treating manufacturer.
3. The name of the fire-retardant treatment.
4. The species of wood treated.
5. Flame spread index and smoke-developed index.
7. Conformance to applicable standards in accordance with Sections R802.1.5.5 through R802.1.5.10.
8. For FRTW exposed to weather, or a damp or wet location, the words “No increase in the listed classification when subjected to the Standard Rain Test” (ASTM D2898).

R802.1.5.5 Strength adjustments. Design values for untreated lumber and wood structural panels as specified in Section R802.1 shall be adjusted for fire-retardant-treated wood. Adjustments to design values shall be based on an approved method of investigation that takes into consideration the effects of the anticipated temperature and humidity to which the fire-retardant-treated wood will be subjected, the type of treatment and redrying procedures.

R802.1.5.6 Wood structural panels. The effect of treatment and the method of redrying after treatment, and exposure to high temperatures and high humidities on the flexure properties of fire-retardant-treated softwood plywood shall be determined in accordance with ASTM D5516. The test data developed by ASTM D5516 shall be used to develop adjustment factors, maximum loads and spans, or both for untreated plywood design values in accordance with ASTM D6305. Each manufacturer shall publish the allowable maximum loads and spans for service as floor and roof sheathing for their treatment.

R802.1.5.7 Lumber. For each species of wood treated, the effect of the treatment and the method of redrying after treatment and exposure to high temperatures and high humidities on the allowable design properties of fire-retardant-treated lumber shall be determined in accordance with ASTM D5664. The test data developed by ASTM D5664 shall be used to develop modification factors for use at or near room temperature and at elevated temperatures and humidity in accordance with ASTM D6841. Each manufacturer shall publish the modification factors for service at temperatures of not less than 80 °F (27°C) and for roof framing. The roof framing modification factors shall take into consideration the climatological location.

R802.1.5.8 Exposure to weather. Where fire-retardant-treated wood is exposed to weather or damp or wet locations, it shall be identified as “Exterior” to indicate there is not an increase in the listed flame spread index as defined by the testing specified in Section R802.1.5.15 when subjected to ASTM D2898.

R802.1.5.9 Interior applications. Interior fire-retardant-treated wood shall have a moisture content of not over 28 percent when tested in accordance with ASTM D3201 procedures at 92-percent relative humidity. Interior fire-retardant-treated wood shall be tested in accordance with Section R802.1.5.6 or R802.1.5.7. Interior fire-retardant-treated wood designated as Type A shall be tested in accordance with the provisions of this section.

R802.1.5.10 Moisture content. Fire-retardant-treated wood shall be dried to a moisture content of 19 percent or less for lumber and 15 percent or less for wood structural panels before use. For wood kiln dried after treatment (KDAT) the kiln temperatures shall not exceed those used in kiln drying the lumber and plywood the wood structural panels submitted for the tests described in Section R802.1.5.6 for plywood and wood.
structural panels and R802.1.5.7-R802.1.5.4 for lumber.

**Reason:** This proposal simply moves fire retardant treated wood (much of which is used indoors or for applications that do not involve roofing) away from the roofing section (in Chapter 8) and places it in chapter 3 (section 302) where all the products with improved fire performance are. It does not make any change to requirements and uses the same code language but in a more appropriate chapter of the code. A pointer sends the user from the section the information used to be (in chapter 8) to the new location.

Section R302 contains information on all the materials associated with “fire resistant construction”, including wall and ceiling finishes, insulation and foam plastics. This is where the information on fire retardant treated wood belongs. Chapter 8 is on roof construction and, as stated above, many uses of fire retardant treated wood are for applications that are not roofs. The proposal keeps in chapter 8 the requirements for the wood products themselves, namely lumber and structural panels, to be consistent with cross-laminated timber and engineered rim wood board and so on. It just moves the requirements specific to fire retardant treated wood.

The changes in this proposal do not alter requirements but just move the sections for logical positioning. The only change in language is in relocated section R802.1.5.10 where the word plywood is replaced by wood structural panel, the title of relocated section R802.1.5.6, which is what is being referred to.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal simply relocates the FRTW sections from the roofing section to a new location, dealing with other fire safety issues, without changing requirements.

Proposal # 5084

RB77-19
Proponent: Kevin Gore, Borough of West Chester, representing Borough of West Chester (kgore@westch.ber.com)

2018 International Residential Code

Revise as follows:

R303.3 Bathrooms. Bathrooms, water closet compartments and other similar rooms shall be provided with aggregate glazing area in windows of not less than 3 square feet (0.3 m²), one-half of which shall be openable. Exception: The glazed areas shall not be required where artificial light and a local exhaust system are provided.

Reason: Typically, during winter and summer months or when inclement weather occurs, occupants fail to utilize windows in bathroom spaces to provide for proper ventilation to control moisture and humidity levels. The failure to utilize natural ventilation and the lack of mechanical ventilation in these spaces leads to mold and/or mildew conditions which can ultimately create unsanitary conditions and cause health problems for the occupants. According to the Centers for Disease Control and Prevention (2017), "In 2004 the Institute of Medicine (IOM) found there was sufficient evidence to link indoor exposure to mold with upper respiratory tract symptoms, cough, and wheeze in otherwise healthy people". Additionally, as we continue to improve the International Energy Conservation Code and enhance the energy efficiency of structures, we defeat the purpose of increased energy efficiency by requiring a window to be open in a space which is being heated or cooled.

Cost Impact: The code change proposal will increase the cost of construction

The cost to supply and install a mechanical exhaust fan is approximately $300.00.
2018 International Residential Code

Revise as follows:

R303.4 Mechanical ventilation. Where the air infiltration rate of a dwelling unit is 5 air changes per hour or less where tested with a blower door at a pressure of 0.2 inch w.c (50 Pa) in accordance with Section N1102.4.1.2, the dwelling unit shall be provided with whole-house mechanical ventilation in accordance with Section M1505.4.

**Exception:** Dwelling units in the tropical climate zone complying with Section N1101.13.1.

**Reason:** To address this issue, two companion code changes have been submitted. RE90-19 addresses Section R403.6 of the IECC residential provisions. This change addresses the same issue in the IRC. Air changes per hour (ACH) is a volumetric metric that is useful for air quality measurements in buildings but is not the correct expression of air leakage from an energy or building durability perspective. This proposal introduces the ability to use an alternative cubic foot per minute (CFM) per square foot (ft²) of dwelling unit enclosure area metric for measuring air leakage in a building. In this way, the air leakage measured at 50 Pascals divided by the building surface area is used to assess the airtightness of the construction and building envelope. Unlike ACH, a CFM/ft² of dwelling unit enclosure area metric normalizes the building air leakage per unit of building envelope surface area; the actual location where air is infiltrating or exfiltrating the building. To this end, the proposal also defines “Dwelling Unit Enclosure Area” as the sum of the area of ceiling, floors, and walls separating a dwelling unit's conditioned space from the exterior or from adjacent conditioned or unconditioned spaces. In addition, the definition offers guidance to further understand the measurement that must take place to calculate the dwelling unit enclosure area. This guidance states that the wall height shall be measured from the finished floor of the dwelling unit to the underside of the floor above. Lastly, the proposal ensures that the intent of the code, to ensure that the structure is built tight and ventilated correctly with mechanical ventilation, is maintained. If an additional option is adopted into the code, as proposed, then ventilation must also be ensured regardless of how air tightness of the structure is expressed.

Since 1980, The Energy Conservatory, has not only been a leader in air leakage science, but also one of the prominent manufacturers of the blower door air measurement tool. In their article, “Which Is A Better Metric For Measuring Airtightness: ACH @ 50 Pa Or CFM/ Ft² Of Surface Area @ 50 Pa?”, which is adapted and added to in this reason statement, we get the basis of the argument for the introduction of a new metric into the International Energy Conservation Code for the measurement of air leakage.

To paraphrase, when measuring the airtightness of a building the objective is to learn how much leakage is occurring across the building’s enclosure area. It is analogous to moisture permeability or the measurement of moisture across the building’s enclosure area and thermal transmittance, the rate at which heat is transferred across the building enclosure area. The rate of air leakage or tightness does not depend on the volume of the structure as defined by the building’s enclosure area but does depend on the holes associated with the surface area of the structure. Air permeability of a material is typically measured as the flow per area at a given pressure difference across the material. U value measurements are similar. If we want a metric to use to measure the airtightness quality of construction of the exterior enclosure of buildings it makes sense to use a metric that equates flow to the size and number of holes in the building’s thermal enclosure.
The article continues with an example to help demonstrate how volume is not proportional to surface area:

Comparison between ACH50 and CFM50/ft² for a 2000 ft² home at 3 ACH50

House Is 50 X 40 X 8

Volume = 16,000 ft³

Surface Area = 50 X 40 X 2 + 180 X 8 = 5440 ft²

CFM50 = (3 X 16000)/60 = 800 CFM

CFM50/ft² = 800/5440 = 0.147 CFM50/ft²

Increase height to 2 story at 3 ACH50

House Is 50 X 40 X 16 Volume = 32,000 ft³

Surface area = 50 X 40 X 2 + 180 X 16 = 6880 ft²

CFM50 = (3 X 32000)/60 = 1600 cfm

CFM50/ft² = 1600/6880 = 0.233 CFM50/ft²

In this example, when the volume is doubled, the surface area increased by 26%. And when the ACH50 stays the same, the CFM/ ft² of surface area increased by 58%. I have attached an Excel spreadsheet calculator that further defines the disconnect between ACH and CFM/ ft² of surface area to further elaborate the issue. In the attached calculator you can change the ratio of width and length of the building to see the effect on the resulting expressions of air leakage. An independent yet similar calculator can be found at this Residential Energy Dynamic link http://www.residentialenergydynamics.com/REDCalcFree/Tools/AirLeakageMetrics

The primary purpose of this code change proposal is to introduce the CFM/ft² of surface area metric into the code. Deciding on where to set the minimum allowable leakage rate is difficult largely due to the earlier volume and surface area discussion. Both tests are performed at a pressure differential of 0.2 inch water gauge (50 Pa), which is a the traditional residential testing pressure so an attempt was made to align the introduction of a CFM/ft² of surface area metric with the existing ACH50 matric of 3 and 5 air changes per hour. ACH being a volumetric measurement penalized small volume dwelling units so a decision was made to concentrate on a size range of dwellings between 2500 and 5500 square feet. By doing this and using the attached conditioned floor space to shell area calculator we were able to see that little variation occurred between ACH and CFM/ft² of surface area metric when changing the size ratio of the modeled house within this house size range. By rounding up, the proposal is using .17 CFM/ft² of surface area metric to align with 3 ACH and .28 CFM/ft² of surface area metric to align with 5 ACH. By using these numbers, small volume homes, while not having a volumetric penalty, are allowed to be a little more leaky and large volume homes must achieve just about the same level of tightness if not a slight bit more. As the average home size in the United States is approximately just less than 2500 square feet this code change proposals purpose of introducing a better measurement metric without removing the codes traditional measurement methodology, provid additional flexibility while maintaining
The Energy Conservatory suggests that the use of Air Changes per Hour at 50 Pa (ACH50) started approximately 60 years ago by researchers who were interested in ways to predict the natural infiltration rate of buildings, which at the time was most commonly measured in Air Changes per Hour. At the time air quality in buildings was being studied and the metric made sense. If a pollutant is released in a building, the time for the concentration to decay by a certain percentage depends on the infiltration measured in air changes per hour. The analysis of a tracer gas decay test gives a result in air changes per hour. So, when they started measuring airtightness, for use in estimating natural infiltration in air changes per hour, it made sense to use ACH50 as the metric.

However, as discussed earlier, two homes with the same volume can have very different surface areas and holes associated with the building enclosure area.

Value is gained by including a surface area-based metric in that air-sealing varies directly with the amount of surface area not the amount of volume in the dwelling. Two buildings can have surface areas that differ by 15%, but have the same volume and the current metric offers the same leakage allowance. Therefore, if the purpose of measuring air leakage is to determine something about the construction quality, air leakage rate, energy efficiency and building durability the metric should be associated with the flow of air through holes in the enclosure. To quantify these things ACH is the wrong metric. It does not tell you anything about the quantity and air leakage through holes in the building. Conversely, the CFM/ft² of surface area metric concretely expresses the quantity of air leakage throught the building’s exterior enclosure. When an enclosure is tight more energy is conserved as well as allowing better control and predictability of air flow, thermal flow, and moisture flow.

Many standards are now using square foot of enclosure area instead of ACH. Examples include EnergyStar, US Army Corp of Engineers, LEED, US Passive House and ASHRAE 62.2. This proposal is the first step to bring this better expression of air leakage into the code. It has been created in such a way that options are maintained allowing jurisdictions and building professionals flexibility in defining air leakage requirements.

Link to Energy Conservatory article from which portions of this reason statement have been added:

https://support.energyconservatory.com/hc/en-us/articles/204176240-Which-is-a-better-metric-for-measuring-airtightness-ACH-50-Pa-or-CFM-ft-of-surface-area-50-Pa-

**Why the change to R403.6?**

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to to ensure whole house mechanical ventilation continues to be required and installed

**Why The change to IRC 303.4?**

It was pointed out in the last code cycle, that this metric could have an unintended loophole since it is not used in the IRC. To avoid that, the section was edited to ensure whole house mechanical ventilation continues to be required and installed

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

There should be no cost implication associated with the adoption of this proposed language. Dwellings will continue to need to be tested and testing prices will not change due to an additional option for how to express
the results of the test.
2018 International Residential Code

Revise as follows:

R305.1 Minimum height. Habitable space, hallways and portions of basements containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). Bathrooms, toilet rooms and laundry rooms shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exceptions:

1. For rooms with sloped ceilings, the required floor area of the room shall have a ceiling height of not less than 5 feet (1524 mm) and not less than 50 percent of the required floor area shall have a ceiling height of not less than 7 feet (2134 mm).
2. The ceiling height above bathroom and toilet room fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a ceiling height of not less than 6 feet 8 inches (2032 mm) above an area of not less than 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.
3. Beams, girders, ducts or other obstructions in basements containing habitable space shall be permitted to project to within 6 feet 4 inches (1931 mm) of the finished floor.
4. Beams and girders spaced not less than 4 feet (1219 mm) on-center shall project not more than 6 inches (152 mm) below the required ceiling height.

Reason: The proposed language was removed in the 2009 IRC because the argument was made that a 4-foot space between beams could not be regulated due to no definitive beam size. We are suggesting 5-1/2" width for a beam to allow a 2x6 wall to be utilized for beam support. The original intent of this section was to allow supportive exposed beams between rooms to be lower than 7 feet. With the engineered lumber and spans larger than normal in homes, beams are larger than traditional nominal lumber.

The removal of this language has left the ceiling height unattainable in many situations. If the current code is to be followed, no beams are allowed to fall below 7 feet in any home, except for basements, which we have defined in Section 305.1 exception 3.

By adding relief to the current code will allow the use of engineered lumber for many situations that are not legal under current code. In practice, this section is either ignored by the code official, or they may need to issue a lot of variances. In section R311.2, we allow a minimum of 78 inches (1981 mm) in height for an egress door. By that logic, we should allow 78 inches (1981 mm) for any transitional opening between rooms. By defining this, we can minimize the confusion of what is allowable height on a beam on any floor other than basements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

Adding relief to the current code will allow the use of engineered lumber for many situations that are not legal under current code.
2018 International Residential Code

Revise as follows:

SECTION R307
TOILET, BATH AND SHOWER SPACES, INCLUDING GRAB BAR PROVISION

R307.1 Space required. Fixtures shall be spaced in accordance with Figure R307.1, and in accordance with the requirements of Section P2705.1.

R307.2 Bathtub and shower spaces. Bathtub and shower floors and walls above bathtubs with installed shower heads and in shower compartments shall be finished with a nonabsorbent surface. Such wall surfaces shall extend to a height of not less than 6 feet (1829 mm) above the floor.

Add new text as follows:

R301.3 Grab bars. Grab bars shall be in accordance with Sections R303.3.1 trough R303.3.7.

R307.3.1 Grab Bar Provision. New bathtubs and showers shall be provided with grab bars complying with Section R307.3. Positioning of the grab bars, including stanchion type grab bars in addition to conventional wall mounted grab bars, shall be such that they are within reach of bathtub and shower users where such users are standing within the bathtub or shower and standing within the clearance spaces required by R307.2 as illustrated in Figure R307.1.

R307.3.2 Shower grab bar. A vertical grab bar shall be provided with a length of at least 24 inches (610 mm) positioned with its lower end not higher than 39 inches (990 mm) above the finished floor, its upper end not lower than 60 inches (1525 mm) above the finished floor, and located either inside or outside the shower enclosure and usable by a person entering and exiting the shower enclosure to occupy the clear floor area required by R307.2.

R307.3.3 Vertical bar for bathtub. A vertical grab bar with a minimum length of 36 inches (915 mm) shall be provided at the unobstructed entrance for the end wall of the bathtub, adjacent to the clear floor area required by R307.2 and positioned with its lower end not higher than 27 inches (685 mm) above the finished floor and its upper end not less than 60 inches (1525 mm) above the finished floor. If wall-mounted, the grab bar shall be between 9 inches (230 mm) and 12 inches (305 mm), measured horizontally, from the exterior plane of the bathtub. If provided as a stanchion extending from the ceiling to the floor or bathtub rim, the vertical bar shall be not more than 6 inches (150 mm) horizontally of the outer edge of the bathtub and not more than 30 inches (760 mm), measured horizontally, from the control end wall or from the water delivery spout in the absence of a control end wall.

R307.3.4. Horizontal or diagonal grab bar for bathtub. At the non-access side of the bathtub there shall be a diagonal or horizontal grab bar with a length of at least 24 inches (610 mm) placed not higher than 10 inches (255 mm) above the rim of the bathtub. If horizontally oriented the bar shall be positioned not higher than 10 inches above the rim of the bathtub and one end no more than 12 inches (305 mm), measured horizontally, from the control end or the water spout location if there is no control wall end. If diagonally oriented, the higher
end shall be not more than 12 inches (305 mm) measured horizontally from the control end wall and between 25 inches and 27 inches (685 mm) above the rim of the bathtub.

R307.3.5. Grab bar details. Grab bars shall be circular in cross section with a minimum diameter of 1.25 inches (30mm) and a maximum diameter of 2 inches (50 mm). There shall be a clearance, for hand grasp, of not less than 1.5 inches (40 mm) between the bar and any surface. Grab bars shall be designed and constructed to withstand a load, in any direction, of 250 pounds minimum. Grab bars shall be designed and constructed with their fixings resistant to corrosion from water and to deterioration, from water, of surfaces and structure to which they are attached.

Reason: Reason Statement for IRC R307, new grab bar requirements in the IRC

General Introduction

Grab bars are what are, more generally, called “points of control” which help us maintain our posture and facilitate movement via our bodily contacts with surfaces underfoot and graspable fixed objects for our hands. For example, stair use requires—for minimum safety—one foot taking our body weight on a step (while the other foot moves between steps) and one hand on a handrail if we need lateral support of our upright bodies and/or some pulling assistance for the stair climb.

Thus, from a code point of view, it is widely accepted that stairs require at least one handrail to assure that at almost all times we have two points of control available when using stairs. The same ergonomic or biomechanical standard has not been generally applied to another dangerous act in buildings, entering and exiting a bathing or showering facility. In a home these facilities will typically require stepping over a bathtub wall or a low dam preventing water from draining onto the floor from a shower pan. This step-over behavior is complicated by the quality of the underfoot surfaces, some wet with water and others insecure due to other conditions (such as a dry towel or mat on a dry but very smooth tile surface) that are precursors to a slip. With this brief, fundamental consideration of the problem and its solution in mind, see Figure 1, a matrix which relates points of control to simplified regulatory strategies, namely how many points of control are enough.

Right now, for bathing/showering on wet, slippery surfaces the point of control at our feet is very dubious and unreliable. And, currently, home bathrooms very, very seldom have any grab bars. The effective level of points of control in most home bathrooms is less than one. As already noted, stairs even in homes provide about two points of control (although, with undersized tread depths and dysfunctional decorative railings instead of function handrails, that figure of two might be closer to one). See Figure 1 for a hierarchy of points of control and situations where bathtubs/showers exist currently with very substandard availability of points of control combined with dangerous, hard surfaces to fall against and, thus, exacerbate injuries.
Therefore, in recent years, there has been an international move to providing one or more new points of control for bathtubs and showers, largely to aid in two types of transfer for bathtubs—transfers in a standing position over the tub wall (for all tub uses) and transferring from a standing position to sitting or lying and later transferring from a lying or sitting position to standing. These bathtub transfers require two different points of control in relation to where the hand(s) are needed for the two types of transfers. Thus for all bathtub transfers two upper body points of control are needed either sequentially or simultaneously—the latter being increasingly important as one ages and loses lower body strength and has greater issues with balance generally. Especially as we get older, we rely more and more on bilateral support on stairs with handrails on both sides and bathtubs where there are points of control on both sides of the tub if we have a bath as opposed to showering.

The most basic package of grab bar requirements for transfers by ambulatory means is a single vertical grab bar reachable from the entrance area of a bathtub or a dedicated shower. If a bath is desired in a tub, then a diagonally oriented or horizontal bar on the non-access side of the tub is needed where there is often a wall on which to attach a conventional grab bar. An option is to use a horizontal stanchion (a bar or tube that is attached between surfaces rather than cantilevered from a surface) attached between end walls of a tub enclosure. See the installation photograph at the end of this Reason Statement; the horizontal stanchion is held in place by two large tiles through which the stanchion tube is passed with the tube ends butted against the wall tile with no hole made in the wall tile so there is no chance of water entry behind the wall tile due to this installation. High-grade adhesive is used to hold the assembly in place meeting the 250-pound load criterion easily.

The foregoing was the rationale used to develop the first set of mainstreamed grab bar requirements in a model building code as well as in a companion, safety standard—specifically NFPA 5000 and NFPA 101 in their 2018
editions and retained in the upcoming 2021 editions. The basic set of criteria that were adopted with very little fuss within the NFPA process has now been used to develop a proposal for the IRC, specifically Section R307 which deals with toilet, bath and shower spaces. This was where some people in ICC, during 2018 hearings for Group A code requirements, recommended a new mainstreamed grab bar requirement should be situated. Their advice has been followed in the proposal now submitted for Group B code requirements. (When the proponent started down this road of trying to get grab bar requirements into the I-codes, he was unaware there were various options on where such requirements might best fit. The consensus on this in last year’s Group hearings was “not here” and, for dwelling units, the logical place to be addressed in Group B was the Planning chapter of the IRC, specifically Section R307 on spaces in bathrooms. Hence, proposed here is the basic, minimum or entry level proposal to mainstreamed grab bars for dwelling units, the most likely context for injuries related to bathtubs and showers.

The Problem of Injuries Associated with Bathtubs and Showers

How Bathtub and Shower-related Injuries Compare to Other Injury Sources. Figure 1 provides a quickly appreciated comparison of the relative size of three problems in buildings: fires, stairs and baths/showers.

![Figure 1. Chart of Approximate Relative Occurrence of Serious Injuries Associated with Three Common Dangers in Homes and Other Buildings](image)

One can quickly see that injuries related to baths/showers greatly outnumber those from fire and that baths/showers are in the same league as stairs in terms of injuries. However, note that when exposure is taken into account, baths/showers are more dangerous. (Exposure will also be addressed in the following section where the other major safety culprit in home bathrooms is briefly noted.)
The central and most important point of this code change proposal is to respond to the relatively high risk of injurious falls when entering and exiting a bathing/showering facility. An organization, PIRE (Pacific Institute for Research and Evaluation), in Maryland is the best available source of some very insightful data collections that have been prepared by likely the finest minds on injury data in the world. PIRE has provided the proponent with data sets that have their origins in the US CPSC National Electronic Injury Surveillance System (NEISS) but have been subjected to intelligent analysis and presentation which are shared here, where they can do a lot of good.

First let us examine data on where (occupancy or building context) bathtub and shower injuries occur in the USA in the years 2010-2014. Table 1(a) provides this data set from PIRE along with a related data set, in 1(b) Table for toilets, the third relatively dangerous facility in home bathrooms.

Tables 1(a) Bathtubs & Showers plus 1(b) Toilets:

Injuries by Locale in the US

Some important preliminary lessons from these tables: first homes are, by far, the most common locale for bathroom-related injuries. People can avoid using showers anywhere, but they need to use toilets everywhere.

Next, let us examine data on rates of injuries by age group and the context of professional treatment for those injuries. Again we compare two tables addressing (a) bathing/showering and (b) toileting.
Tables 2(a) Bathtubs & Showers plus 2(b) Toilets:

Injury Rates by Age & Treatment Context

Some important preliminary lessons from these tables: First, note the heightened vulnerability of older adults to injuries—at rates ten to a hundred times higher than for younger and middle-age adults. Second, note for the very oldest people, toilets are especially dangerous because their use—or avoidance of use—is not by choice as is the case for showers and baths. Third, note for the oldest people, injuries tend to be very serious as the rate for minor treatment is close to the rate for hospital admission.

Next, let us examine data on incidence (estimated number) of injuries by age group and the context of professional treatment for those injuries. Again we compare two tables addressing (a) bathing/showering and (b) toileting.
Tables 3(a) Bathtubs & Showers plus 3(b) Toilets:

Injury Incidence by Age & Treatment Context

Some important preliminary lessons from these tables: Note that there are many injuries occurring to younger people so their greater preference for frequent bathing/showering is not reduced by the dangers; they still fall due to factors that go beyond fraility and/or balance issues that increase with older people. Their injuries might be less severe but they are still highly vulnerable to incidents with balance or footing, for example, from which they are less likely to be hurt very badly. In other words, there are problems to be addressed across the life span with bathing/showering.

The societal cost of these injuries was (for 2010) about 20 billion dollars for US bathtubs plus showers and about 93 billion dollars for US stairs with the greatest risk for both being in homes, where bathing/showering is a near daily activity for most people in the US (Data source: Lawrence, B., Spicer, R., Miller, T. A fresh look at the costs of non-fatal consumer product injuries. Injury Prevention, digital publication, August 2014, paper journal publication, 2015:21:23-29.)

Source of the Text of the Proposed New Requirements for IRC Section R307.3

The source of the proposed new requirements is a few sources, first the proponent’s proposals of last year for Group A changes to the IBC (first Means of Egress, Ch. 10 and later Interior Environment, Ch. 12) and the IRC (plumbing). A Comment was submitted only for the IBC knowing already that there were numerous suggestions
that the best place in the IRC was not for a section in Group A; it was the Planning Chapter in Group B.

Other sources include activity in Canada on two separately submitted proposals, from 2007 and 2015, for mainstreamed grab bars, first only in homes and later in all occupancy contexts.

The best source was the proposals that have actually been incorporated in a major set of documents, NFPA 5000 and NFPA 101. The latter, in addition to adopting a package of requirements for mainstreamed grab bars in virtually every non-healthcare occupancy, adopted a new scoping provision (1.1.6): “Injuries from Falls. The Code also addresses reducing injury to occupants from falls.” (NFPA 5000 already had such an expanded scope from its inception.) The proponent for both the successful mainstreamed grab requirements and the new scope statement was the current proponent of the two proposals to the I-Codes in Group A in 2018 and is the proponent of this proposal in Group B during 2019.

To be specific, for a few reasons the proponent elected to pattern the now-proposed requirements, for an expansion of IRC R307.3, on what NFPA has adopted and will soon include in its next code editions, the 2021 editions of NFPA 5000 and NFPA 101. This is not done out of loyalty to NFPA but, more fundamentally, because with all the discussions that have been going on internationally over the last two decades on improved bathroom safety, there is a consensus emerging on what a package of mainstreamed grab bar proposals should contain. So, bottom line, the ICC has a widely considered proposal in Group B for the IRC during 2019. They have had much discussion and, as noted in last year’s proposals, the proponent is a devoted documenter of bathrooms in hotels in many countries due to, first, his attention to detail and, second, the need to document bathroom facilities to near-forensic standards for his 130 nights of travel using a variety of hotels, with rooms in a wide range of price categories, each year.

Finally, the proponent practices what he preaches; see Figure 2 for the bathroom in his dwelling unit; it would readily comply with the proposed IRC requirements.

![Figure 2. Bathroom Retrofitted (in a rental apartment)](image)

with Mainstreamed Grab Bar Set That Would Comply

with the Proposed IRC Requirements for R307.3
Bibliography: An extensive bibliography of about 50 items was provided with all the Group A proposals on grab bars. That can be obtained from cdpAccess archives as well as from the proponent. There was only one citation to the literature in this Group B proposal and all the usual bibliographic information was included in the Reason Statement text.

Cost Impact: The code change proposal will increase the cost of construction
From careful analysis on related code change proposals in Canada (where an Impact Analysis is being required for many proposed changes to the National Building Code of Canada. The bottom line is that the payback period for the few hundred dollars of materials and labour to install two grab bars per shower-bathtub combination in a dwelling, even for two bathrooms in such a dwelling, is on the order of several years. After that, the grab bars just keep preventing and mitigating falls for decades, given the large cost of bathing/showering-related injuries as discussed in the Reason Statement.

Proposal # 5619

RB81-19
RB82-19
IRC®: R308.4.5 (New)

Proponent: Lucas Pump, representing Self (l.pump@cedar-rapids.org)

2018 International Residential Code
Revise as follows:

R308.4.5 Glazing and wet surfaces. Glazing in walls, enclosures or fences containing facing or facing adjacent to hot tubs, spas, whirlpools, saunas, steam rooms, bathtubs, showers and indoor or outdoor swimming pools where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) measured vertically above any standing or walking surface shall be considered to be a hazardous location. This shall apply to single glazing and each pane in multiple glazing.

Exception: Glazing that is more than 60 inches (1524 mm), measured horizontally and in a straight line, from the water’s edge of a bathtub, hot tub, spa, whirlpool or swimming pool or from the edge of a shower, sauna or steam room.

Reason: This code change proposal provides clarification on where safety glazing is required when adjacent to wet surfaces. This section has come up a number of times in our jurisdiction and there is always confusion on whether the adjacent wall next to a tub/shower needs safety glazing, or just the wall “facing” the tub/shower as specifically stated in the code. We believe the intent is similar to that of a landing at the bottom of the stairs, which requires any glazing within a 60 inch arc to be safety glazing. If you step out of a tub/shower, you are just as likely to slip and fall to the side as you are to fall forward. For this reason we believe simply adding the words “adjacent to” will make this more clear. This proposal adds language that would support safety glazing in a window next to a bathtub on the wall adjacent to a bathtub/shower.

Wet Surfaces

Cost Impact: The code change proposal will not increase or decrease the cost of construction
I believe that this wouldn't increase the cost of construction, because most inspectors and contractors are interpreting this area as being required to be safety glazing already.
2018 International Residential Code
Revise as follows:

R308.6.3 Screens, general. For fully tempered or heat-strengthened glass, a retaining broken glass retention screen meeting the requirements of Section R308.6.7 shall be installed below the full area of the glass, except for fully tempered glass that meets either condition 1 or 2 listed in Section R308.6.5.

R308.6.4 Screens with multiple glazing. Where the inboard pane is fully tempered, heat-strengthened or wired glass, a retaining broken glass retention screen meeting the requirements of Section R308.6.7 shall be installed below the full area of the glass, except for either condition 1 or 2 listed in Section R308.6.5. Other panes in the multiple glazing shall be of any type listed in Section R308.6.2.

R308.6.5 Screens not required. Screens shall not be required where laminated glass complying with item 1 of Section R308.6.2 is used as single glazing or the inboard pane in multiple glazing. Screens shall not be required where fully tempered glass is used as single glazing or the inboard pane in multiple glazing and either of the following conditions are met:

1. The glass area is 16 square feet (1.49 m²) or less; the highest point of glass is not more than 12 feet (3658 mm) above a walking surface; the nominal glass thickness is not more than 3/16 inch (4.8 mm); and the other pane or panes are fully tempered, laminated or wired glass.

2. The glass area is greater than 16 square feet (1.49 m²); the glass is sloped 30 degrees (0.52 rad) or less from vertical; and the highest point of glass is not more than 10 feet (3048 mm) above a walking surface.

R308.6.7 Screen characteristics. The screen and its fastenings shall be capable of supporting twice the weight of the glazing; be firmly and substantially fastened to the framing members; be installed within 4 inches (102 mm) of the glass; and have a mesh opening of not more greater than 1 inch by 1 inch (25 mm by 25 mm).

Reason: The current language that states when screens are required below unit skylights glazing has frequently been difficult to interpret by jurisdictions, causing consumers and others concern when they are incorrectly told they need to install a glass retention screen below conforming laminated glass. Skylight manufacturers are asked to intervene far too frequently to ensure that unsightly, unnecessary screens are not installed in these instances. Furthermore, it is believed that many times an optional skylight installation is removed from submitted plans due to misinterpretation at the plan check stage, where the supplier may never know that the issue was raised because the permit applicant chooses to surrender rather than appeal. The current code language addresses qualifying laminated glass by simple omission from the sections dealing with screens. It is this omission that seems to create the confusion within the industry. The proposed additional sentence in Section R308.6.5 states directly that permitted laminated glass does not require screens. This should reduce the frequency of misinterpretations that have been experienced.

Adding the modifier, “broken glass retention” fully describes the screen’s purpose. This is to ensure readers do not confuse them with insect screens or fall protection screens, which are physically different and will not serve
as effective retention screens.

Section R308.6.7 is further clarified to be consistent with the language in IBC Section 2405.3.

None of the proposed changes affect the long-standing requirements; rather, the only expected outcomes are simply better clarity that will then provide more consistent enforcement.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal should have a nominal effect on the cost of construction as the changes presented are not meant to alter the current requirements but simply meant to provide better clarity and more consistent enforcement.

Proposal # 5259

RB83-19
2018 International Residential Code

Revise as follows:

R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions - Exception:

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:
   2.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311.

Reason: This exception was introduced to the 2018 IRC to encourage the installation of fire suppression systems. Egress windows should not be removed from a sleeping area or room. Bedrooms in a basement are unique in the fact they are in a concrete bunker essentially. Should a fire event happen at or near the door you will have no option to self-evacuate if you do not have an egress window. I have heard basements described by fire crews as a large oven as they contain and radiate the heat in a confined space. Putting all the egress expectations on a system with an effective design time of possibly 6 minutes versus an opening which will always be available is a no brainer. Egress windows are also used for rescue and ingress for fire crews to attack the event. Last, unlike the IBC and IFC, IRC systems are not required to be inspected annually and maintenance is dependent on the owner who could remove the head, modify the head or paint over the head effectively hampering or removing this system as an egress option. And, now they have no window either…

Cost Impact: The code change proposal will increase the cost of construction
This change could increase the cost of construction if you were to install a suppression system.

Proposal # 5607
2018 International Residential Code

Revise as follows:

R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions:

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement, story, habitable attic or mezzanine in which the sleeping room is located has one of the following:
   2.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311.

Reason: This proposal suggests an extension of the means of escape window allowance, added last cycle by RB89-16 (which duplicates an IBC exception added by E145-15). The current application, which is limited to basements of sprinklered dwelling units, would be applicable to all levels, provided that each level using the exception has at least one escape window or door in addition to a code-compliant means of egress, such as an interior stair or a door to the outside. It is important to remember that means of escape openings are in the code due to fire concerns and are sized based on a firefighter in full turnout gear going through the opening. Where sprinklers and hard-wired interconnected smoke alarms are present there is minimal prospect of a firefighter having to make entry through or an occupant having to escape via a window opening.

Precedent for extending this exception is well established by the NFPA 101 - Life Safety Code, which allows eliminating ALL required means of escape openings from sprinklered one- and two-family dwellings [24.2.2.1.2(2)], hotels, motels, apartments and similar uses. In addition, the states of New Hampshire and Virginia have both amended R310.1 of their statewide code adoptions by eliminating ALL requirement for means of escape openings when sprinklers are provided. This proposal is more conservative by retaining a requirement for at least one means of escape plus the means of egress from each level.

This proposal offers significant value to builders, architects, homeowners and firefighters. For builders, architects and homeowners, the proposal offers significant design flexibility and choice of where and how to locate windows when a dwelling unit is equipped with a fire sprinkler system. There is particularly beneficial for cases where it is difficult, or perhaps impossible, to provide a complete path from a sleeping room means of escape to a public way due to pathway obstructions created by fences isolating townhouse yards, rooftop solar arrays or other obstacles. For firefighters, it is far safer to respond to a sprinklers home than a non-sprinklered home, and reasonable and appropriate incentives, such as this one, encourage and recognize the value of residential sprinkler installations.
Disclosure: although I am a consultant to the National Fire Sprinkler Association, this proposal is submitted on my own behalf and was not reviewed or endorsed by NFSA prior to submittal.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal adds an option to the code. There is no requirement to utilize this option; however, if it is used, the cost of construction may decrease.
Proponent: Thomas Barrs, City of Scottsdale, representing Self (tbarrs@scottsdaleaz.gov)

2018 International Residential Code

Revise as follows:

R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a minimum 36" wide yard or court that opens to a public way.

Exceptions:

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:
   2.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311.

Reason: 1. The current requirement for yards and courts to “open directly into a public way” or “opens to a public way” does not specify a minimum width.
2. Both the IRC and IBC use the defined terms ‘yards’ and ‘courts’, however only the IBC in Section 1028 for Exit Discharge provides specific language for minimum width of a court as “Egress courts serving Group R-3 and U occupancies shall be not less than 36 inches.” This code change provides uniformity with the IBC, and a minimum level of safety by including a width for both emergency egress and fire department access.
3. Without this code change, developers, designers, and code officials are provided with no width criteria for yards or courts that must be provided as links to the public way from emergency escape and rescue openings.

Note: The graphic is intended to depict a general example of townhouse and a single family dwelling where the 36" width portion of the yard or court may link from a rear yard or court, to a side yard, then link to a public way. Emergency Escape and Rescue Openings may be from various locations, on various stories, from sleeping rooms, basements, etc., which are not depicted here, but are presently required to "open to a public way", or from "yards" or "courts" to a public way.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. By providing a uniform width requirement, jurisdictions which allowed lesser widths may see an increase in costs, however other jurisdictions that required a larger width due to lack of a specified width, may see a reduction in costs.
R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions:

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:
   2.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311 approved detection devices.
3. A yard shall not be required to open directly into a public way where the yard opens to an unobstructed path from the yard to the public way. Such path shall have a width of not less than 36 in. (914 mm).

Reason: The purpose of this code change is to allow an EERO to discharge into a fenced yard that does not directly open onto a public way if a minimum 36” wide path can be provided from the fenced yard to the public way. In many cities, new townhouses are being constructed on infill lots with tight space limitations. Locating an EERO while also wanting to provide fenced yards is becoming tricky. In some cases, a builder may want to construct two rows of townhouses that are tight up to the street but that have fenced backyards for each unit. Under the current code, the builder would either have to construct a window well in the sidewalk to access a basement EERO or in the backyard and forgo the private fenced yards as there will likely not be enough space to provide a 10 foot wide “public way”. The problems with placing an EERO in the front to allow a fenced yard in the back include coordinating the location with entry doors and front steps, coordinating the location with utilities, and providing a cover over the window well that prevents passers-by from dropping trash into the window well or getting high heels stuck in the openings of a grate. The problem with forgoing fenced yards is obviously the loss of privacy.

While a 10-foot wide path between back-to-back fenced yards is almost certainly not feasible, a 3-foot path may be in many cases. The new exception would allow such a path, that occupants could use to get out of their yard after escaping through an EERO or that firefighters could use to access the fenced yard for firefighting and rescue operations without having to bash through or climb over a series of fences. The assumption is that the yard opens via a gate with access to the public way.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The code change does not change the requirement to provide an EERO for sleeping rooms and for basements...
(including each sleeping room in a basement). Thus, there should be no increase in cost as a result of this proposal. There may be a modest savings from the added ability to locate a basement EERO in the rear of the home, where covers may not be required and coordination with utilities is easier.

Proposal # 4734

RB87-19
**2018 International Residential Code**

Revise as follows:

R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

**Exceptions:**

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:
   2.1. One means of egress complying with Section R311 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311.
3. A yard shall not be required to open directly into a public way where an infill property is located next to adjoining neighboring properties without rescue openings that do not open directly into a public way.

**Reason:** The purpose of this code change is to address the condition where infill lots, and single lot new residential construction (i.e. townhomes/rowhouses), do not have the capacity for rescue openings to open directly into a public way. An infill project may not have the ability to comply with the rescue opening requirements by having access to a public way because the front yard may be non-existent, utility lines, steps and other constraints prevent placing an area well in the sidewalk, the side yards are non-existent due to party walls, and the rear yard may already be delineated without access to a public way due to the neighboring conditions, existing historic design of the neighborhood, or landlocked properties. This occurs in particular where fenced-in yards already exist for the neighboring properties.

The problem is that since an infill project is considered new construction, compliance with zoning laws and ordinances, and for some projects historic design criteria, has led to denials of building permits. The code provisions have created a conflict between trying to maintain the architectural character of the neighborhood and meeting what the building code requires for new construction.

If a rear yard is required to open to a public way, and is next to adjoining existing neighboring properties with yards not opening to a public way, the code will affect the viability of the new infill project and where bedrooms can be located within the residence. With no public access in the rear yard or side yards, due to party walls or existing fences, all bedrooms will have to be located at the front of residence as that may be the only unobstructed path to a public way since sleeping areas require an emergency escape rescue opening. Basements may have to be left unfinished or used only for storage and utilities. This potentially reduces the market value of the new infill property relative to its neighbors since the adjoining properties do not have to...
follow the EERO requirements for new construction.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change will not increase or decrease the cost of construction since the new infill construction design intent is to match the neighboring existing properties also without rescue openings not opening directly into a public way.

Proposal # 5075
RB89-19
IRC: R301.1 (New), R310.1

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Residential Code
Revise as follows:

SECTION R310
EMERGENCY ESCAPE AND RESCUE OPENINGS

Add new text as follows:

R310.1 General. Emergency escape and rescue openings shall comply with the requirements of this section.

Revise as follows:

R310.2 Emergency escape and rescue opening Where required. Basements, habitable attics and every sleeping room shall have one or more emergency escape and rescue openings. Where basements contain an opening in accordance with this section, Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room, but shall not be required in adjoining areas of the basement. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions:

1. Basements with a ceiling height of less than 80 inches (2032 mm) shall not be required to have emergency escape and rescue openings.

2. Emergency escape and rescue openings are not required from basements or sleeping rooms that have an exit door or exit access door that opens directly into a public way or to a yard, court or exterior egress balcony that opens to a public way.

3. Storm shelters and basements used only to house mechanical equipment and not exceeding a total floor area of 200 square feet (18.58 m²) shall not be required to have emergency escape and rescue openings.

4. Storm shelters are not required to comply with this section where the shelter is constructed in accordance with ICC 500.

5. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:

   2.5.1 One means of egress complying with Section R311 and one emergency escape and rescue opening.

   2.5.2 Two means of egress complying with Section R311.

Reason: The intent of this proposal is to coordinate with the approved changes to INC (E107-18 AMPC1) and clarify the exceptions.

Adding Section R310.1 is to coordinate with the format modification made by the public comment to E107-18.

There are revisions to the exceptions for where emergency escape and rescue openings are required.
Exceptions 1 and 2 are current exceptions for EEROs in the IBC. New exception 1 is for basements with ceiling so low that they would not typically include normally occupied spaces. New exception 2 is to allow for the option of a door. The current exception 1 has been divided into new exceptions 3 and 4. New exception 3 clarifies that the 200 sq.ft. limit was for basements that only house mechanical equipment. The new exception 4 separates out storm shelters and adds a specific reference for ICC 500 (currently referenced in ICC R323). The current exception 2 is renumbered only.

This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This is a coordination item for exceptions for EEROs already permitted between the codes.

Proposal # 4143

RB89-19
Proponent: Samuel Steele, representing Seattle Department of Construction and Inspection (SDCI)
(samuel.steele@seattle.gov)

2018 International Residential Code

Revise as follows:

R310.1.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge. Window opening control devices on windows serving as a required emergency escape and rescue opening shall be not more than 70" (177.8 cm) above the finished floor and shall comply with ASTM F2090.

Reason: The 70" (177.8 cm) is the sum of the dimensions in the attached example of a single hung egress window having a maximum 44" sill height with a 24" operable leaf. Added to this is 2" to reach the latch to unlock the window which is set at 70". Similarly on a casement window, the lock should also be no higher than 70" (177.8 cm).

Unlike the dimensions for clear area, sill height, and minimum openings, a height has never been determined for the location of window controls for emergency and escape openings. This would make it very clear for all users of the code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
This merely indicates the height of where the control should be. It would not add any cost to the manufacturing and installation.
2018 International Residential Code

Revise as follows:

R310.1.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge. Window opening control devices complying with ASTM F2090 shall be permitted for use on windows serving as a required emergency escape and rescue opening shall comply with ASTM F2090.

Reason: This revision makes the operational and opening control devices provisions in the IRC consistent with the same provisions in the IBC. The proposed language above was approved for the IBC during the last cycle because further clarity regarding the permitted installation of window opening control devices (wocd’s) compliant with ASTM F2090 on EERO windows was determined to be helpful. While allowing the use of F2090 WOCD’s on EERO windows is implied and intended by this section and Section R312.2, and in addition, the purpose of F2090 is specifically for WOCD’s with emergency release mechanisms for use on EERO windows, providing more express language under Section 310.1 will provide further clarification that the installation of F2090 compliant devices is permitted on EERO windows, and again will make this provision consistent with the same in the IBC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. However, it will avoid potential misinterpretation in the field that could be problematic.
Proponent: Jeff Inks, representing Window and Door Manufacturers Association (jinks@wdma.com); Jennifer Hatfield, representing American Architectural Manufacturers Association (jen@jhatfieldandassociates.com)

2018 International Residential Code

Revise as follows:

R310.1.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools, or special knowledge.

Window opening control devices on windows serving as a required emergency escape and rescue opening shall comply with ASTM F2090.

Reason: This proposal removes the term “special knowledge” to be consistent with the same operational constraint provision in the IBC. The term is undefined and ambiguous and is not necessary.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal is intended to make the IRC consistent with the IBC.
2018 International Residential Code

Revise as follows:

R310.1.1  Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools or special knowledge. Window opening control devices and fall prevention devices complying with ASTM F2090 shall be permitted for use on windows serving as a required emergency escape and rescue opening shall comply with ASTM F2090.

Reason: The term "special knowledge" was removed from IBC because the phrase “special knowledge’ is too open for interpretations.

The revision to the last sentence could not require opening control devices or fall prevention devices. This section would just allow for them to be on windows that were also serving as emergency escape and rescue openings. ASTM F2090, Specification for Window Fall Prevention Devices with Emergency Escape (Egress Release Mechanisms), includes criteria for window fall prevention devices and window opening control devices (see Section R312.2). This standard is specifically written for window openings within 75 feet (22 860 mm) of grade and specifically allows for windows to be used for emergency escape and rescue. This standard was updated in 2008 to address window opening control devices. This control device can be released from the inside to allow the window to be fully opened in order to comply with the emergency escape provisions in IRC.

This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is a coordination item for emergency escape and rescue openings.

Proposal # 4144
2018 International Residential Code

Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

Revise as follows:

R310.2 Emergency escape and rescue openings. Emergency escape and rescue openings shall have minimum dimensions as specified in this section in accordance with Sections 310.2.1 through 310.2.3.

R310.2.1 Minimum opening area size. Emergency and escape rescue openings shall have a net clear opening of not less than 5.7 square feet (0.530 m²). The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. The net clear height of the opening shall be not less than 24 inches (610 mm) and the net clear width shall be not less than 20 inches (508 mm):

Exception: Grade floor openings or below grade openings shall have a net clear opening area of not less than 5 square feet (0.465 m²).

Add new text as follows:

R310.2.2 Minimum dimensions. The minimum net clear opening height dimension shall be 24 inches (610 mm). The minimum net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

Revise as follows:

R310.2.2 R310.2.3 Window sill height. Maximum height from floor. Where a window is provided as the emergency escape and rescue opening, it shall have a sill height of not more than the bottom of the clear opening not greater than 44 inches (1118 mm) above the floor; where the sill height is below grade, it shall be provided with a window well in accordance with Section R310.2.3.

R312.2.2 Window opening control devices. Window opening control devices shall comply with ASTM F2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit to less than the area required by Section R310.2.1 and R310.2.2.

Reason: The intent of this proposal is to clarify minimum size, dimensions and height for emergency escape and rescue openings.

R310.2.1 and R310.2.2 - The requirements for size and dimensions have been split into two sections. The exception does not need to say 'below grade' as this could be considered a conflict with the definition (i.e., 44" above or below finished grade).

R310.2.3 - The revision clarifies that the 44" is to the bottom of the opening. The sill can be interpreted a lot of different ways. Window well requirements are in a new section - a reference from here is redundant and not needed.

The change to R312.2.2 is correlation only.
This is one of a series of proposals to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a coordination item for requirements for EEROs already permitted between the codes.

Proposal # 4147

RB94-19
Proponent: donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)

2018 International Residential Code

Revise as follows:

R310.2.2 Window sill-clear opening height. Where a window is provided as the emergency escape and rescue opening, it-the bottom of the clear opening shall have a sill-height of not more than 44 inches (1118 mm) above the floor; where the sill height-the bottom of the clear opening is below grade, it shall be provided with a window well in accordance with Section R310.2.3.

Reason: Remove the word “sill” with respect to windows and rather use the terminology “clear opening” as this is the critical portion of the window from which to measure, to ensure access to, or when requiring fall protection. This change will provide greater consistency within the text since R310 and R312 reference “clear opening” to describe the requirements of the allowable size of a window.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This Code Change will not affect the cost of construction

Proposal # 5053
**2018 International Residential Code**

Revise as follows:

**R310.2.2 Window sill-opening height.** Where a window is provided as the emergency escape and rescue opening, it shall have a sill height of the bottom of the clear opening shall be not more than 44 inches (1118 mm) above the floor; where the sill height the bottom of the clear opening is below grade, it shall be provided with a window well in accordance with Section R310.2.3.

**Reason:** This proposal is to change the existing language back to what was changed in 2012. It was changed to the current language in 2015 (and stayed the same in 2018) with no apparent reason since it was a part of a larger change. This same language was changed for the 2012 (RB41-09/10) to measure to bottom of opening since it is confusing to what a sill is (no definition) and sills can be much lower than the bottom of opening especially with the heights of the window tracks on a lot of current vinyl windows. I am proposing to change this language back to what was in the 2012. This would also match the current language in IBC section 1030.3.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal will not increase or decrease the cost of construction. It will only clarify what the intent of the code is.

Proposal # 4519
2018 International Residential Code

Revise as follows:

R310.2.3 Window wells. The horizontal area of the window well shall be not less than 9 square feet (0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened, and installed safety grates or covers to be fully opened, and remain open without physical assistance to keep them open. The height of the well shall not exceed one (1) foot above the surrounding soil level except as approved.

**Exception:** The ladder or steps required by Section R310.2.3.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the window well.

R310.2.3.1 Ladder and steps. Window wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the window in the fully open position. Ladders or steps required by this section shall not be required to comply with Section R311.7. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the window well.

Add new text as follows:

R310.2.3.2 Window Well Coverings. Window well covers, grates, and similar structures shall meet the following requirements:

1. Safety or security grates or structures and protective covers shall not exceed 25 lbs in total;
2. Grates or structures shall be hinged or otherwise attached such that they will remain open without human support while exiting the well;
3. Locks or other deterrent mechanisms shall not be installed without the ability to release them from inside the well.

Reason: Purpose for Requested Change:

As a home inspector, I see many creative design installations for items required by locally approved ICC new construction building codes. Tying the reason for a code to the design and implementation of the requirement, and then to the effective design functionality of the product created, in this instance leaves me with much concern for the safety of children or adults of limited physical means needing to use the installed escape route through a below grade window or below grade door and up through a well and grate covering.

Assumptions:

1) The minimum age for which the egress opening shall be intuitively functional is age four (4). In other words individuals of age four or greater shall be able to exit the window or door, structure, and well without any training or prior experience;
2) Any occupant in the structure who meets three components of physical capability (agility, balance, and muscular strength) shall be able to exit the window or door, and climb the well, open any grate and cover and escape to safety.
3) Occupants with physical limitations that limit the following abilities - agility, balance, and muscular strength -
may not be able to exit these emergency egress windows and wells, and are cause for further discussion.

**Changes Requested to current installations:**

1) Limit the height of the well above the surrounding grade
2) Limit the combined weight of any installed safety grate and other covering components (i.e. rain protective coverings)
3) Require that if a safety grate is installed, the grate shall be mounted such that it cannot be removed without tools (hinges or other mechanical balance system)
4) Require that any grate or covering material shall not be locked or secured such that it cannot be opened from the interior of the well by an average person
5) Require that any grate or covering shall be able to be pushed to and remain in a safe open position
6) Require that stairs be secured such that they remain secure while initially grabbing and while climbing, and cannot be removed from the well (already in the code but not being implemented)
7) Safety railings can be used in place of a horizontal grate to protect against injury from falling into a well.

**Reasons and Examples for the Changes:**

1) Weight - Current typical weight of the steel grates are upwards of 40 lbs.
2) Height - Some installed wells are built such that reaching the top of the well would requires steps on the exterior of the well to fully escape for some people.
3) Windows & locks - Can the windows be successfully unlocked and opened by a child? Many installed sash or slider windows are installed tight, bind, and are difficult for a fully functional adult to open and climb the 44 inches over the interior ledge.
4) Grates - In areas that are prevalent to break-ins, the grates may have a locking mechanism installed, which would require a key or other way to unlock or unlatch the grate cover.
5) Stairs - Although in the current code, many stairs are found to be hanging loose, are removable, or are dangerously unstable when climbing.

**Cost Impact:** The code change proposal will increase the cost of construction
The requested code changes may impact construction costs for companies that are not following the current code or are minimally designing and constructing egress wells, but may be negligible for companies currently dedicated to constructing safe egress wells. So costs would vary based on design implementations.
Proponent: Timothy Swanson, representing Colorado Chapter of the ICC (tim.swanson@greeleygov.com)

2018 International Residential Code

Revise as follows:

**R310.2.4 Emergency escape and rescue openings under decks, porches and porches, cantilevers.**

Emergency escape and rescue openings installed under decks, porches and porches, cantilevers shall be fully openable and provide a path not less than 36 inches (914 mm) in height to a yard or court.

**Reason:** As with decks and porches, the potential also exists for cantilevers to be located directly over EERO's.

**Bibliography:** None

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

When openings for potential EERO's are detailed for a basement in the planning/design stage, they can be located anywhere at that time. There would be no additional cost at that stage to properly locate the opening away from a cantilever.
2018 International Residential Code

Revise as follows:

R310.2.4 Emergency escape and rescue openings under decks and porches. Access to a yard or court.
Emergency escape and rescue openings installed under decks and porches shall be fully openable and provide an unobstructed path not less than 36 inches (914 mm) in height and 36 inches (914 mm) in width to a yard or court.

Reason: This proposal simplifies the existing code language by eliminating a potential list of items and provides a performance parameter for a clear path to a court or yard to meet egress and ingress requirements. I maintained the minimum height requirement of 36 in and added a minimum width requirement of 36 inches. The code was previously silent on width. I have no technical justification for a 36” minimum width. It just made sense to have a consistent width if you had to crawl any distance with full fire gear and hose or while trying to extract someone who may not be conscious.

I know Titles are not code but felt necessary to change the title to give the reader a brief detail of what this section is about

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This code change will not increase or decrease the cost of construction.

Proposal # 5592
2018 International Residential Code

Add new text as follows:

**R310.4 Area wells.** An emergency escape and rescue opening where the bottom of the clear opening is below the adjacent grade shall be provided with an area well in accordance with Sections R310.4.1 through R310.4.4.

Revise as follows:

**R310.2.3 R310.4.1 Window wells. Minimum size.** The horizontal area of the window area well shall be not less than 9 square feet (0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area size of the window area well shall allow the emergency escape and rescue opening to be fully opened.

**Exception:** The ladder or steps required by Section R310.2.3.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the window area well.

**R310.2.3.1 R310.2.4.2 Ladder and steps.** Window area wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanent ladder or steps. The ladder or steps usable shall not be obstructed by the emergency escape and rescue opening where the window or door is in the fully open position. Ladders or steps required by this section shall not be required to comply with Section R311.7. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the window well.

Add new text as follows:

**R310.4.2.1 Ladders.** Ladders and rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the area well.

Revise as follows:

**R310.2.3.2 R310.2.4.3 Drainage.** Window area wells shall be designed for proper drainage by connecting to the building's foundation drainage system required by Section R405.1 or by an approved alternative method.

**Exception:** A drainage system for window area wells is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1-R405.1.

**R310.4 R310.4.4 Bars, grilles, covers and screens.** Where bars, grilles, covers, screens or similar devices are placed over emergency escape and rescue openings, area wells bulkhead enclosures, or window area wells that serve such openings, the minimum net clear opening size shall comply with Sections R310.2.1 through R310.2.2, and shall be releasable or removable from the inside without the use of a key, tool or special knowledge or force greater than that required for the normal operation of the escape and rescue opening.
R310.3 Emergency escape and rescue doors. Where a door is provided as the required emergency escape and rescue opening, it shall be a side-hinged door or a slider. Where the opening is below the adjacent grade, it shall be provided with an area well. sliding door.

Delete without substitution:

R310.3.1 Minimum door opening size. The minimum net clear height opening for any door that serves as an emergency and escape rescue opening shall be in accordance with Section R310.2.1.

R310.3.2 Area wells. Area wells shall have a width of not less than 36 inches (914 mm). The area well shall be sized to allow the emergency escape and rescue door to be fully opened.

R310.3.2.1 Ladder and steps. Area wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the door in the fully open position. Ladders or steps required by this section shall not be required to comply with Section R311.7. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the exterior stairwell.

R310.3.2.2 Drainage. Area wells shall be designed for proper drainage by connecting to the building’s foundation drainage system required by Section R405.1 or by an approved alternative method.

Exception: A drainage system for area wells is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

Reason: This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings.

The intent of this proposal to clarify and coordinate the requirements for area wells at emergency escape and rescue openings (EERO) that are below grade (current R310.2.3 and R310.3.2). This does NOT delete doors as an option. This recognizes that windows and doors are both types of emergency escape and rescue openings. The term 'area well' will apply for both windows or doors. The IBC correlating change was E111-18(AS)

- IRC R310.4 - This general paragraph clarifies that the bottom of the EERO sets the requirements for the area well.
- IRC R310.4.1 - Revisions for consistent terminology.
- IRC 1030.4.2 - The sentence about the window not obstruction the steps or ladder is a safety feature. The requirements for ladders has moved into a separate section-R310.4.2.1. Requirements for steps are addressed in another proposal since they are new.
- IRC R1030.4.3 - Since the code always allows alternative means, the last phrase is not needed.
- IRC R310.4.4 - Revisions for coordination. The reference to emergency and escape opening size and minimum area well size. The term “special knowledge is removed to be consistent with IBC and IRC R310.1.1 – the term allows for too broad of an interpretation.
- IRC R310.3 - The last sentence in R310.3 is deleted as redundant since the criteria for area wells is specifically addressed later in Section 310.4.
- IRC Section R310.3.2, R310.3.2.1 and R310.3.2.2 – delete the separate area well requirements for doors.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the
ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is a coordination item for requirements for EEROs already permitted between the codes.

Proposal # 4153

RB100-19
Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org)

2018 International Residential Code

Add new text as follows:

**R310.4.2.2 Steps.** Steps shall have an inside width of at least 12 inches (305 mm), a minimum tread depth of 5 inches (127 mm) and a maximum riser height of 18 inches (457 mm) for the full height of the area well.

**Reason:**
The overall plan is to have area wells address in a comprehensive manner. Following the graphics for this proposal is how this option of steps will fit in with this group of changes. Area wells less than less than a 44" depth will NOT have to comply with the step provisions. Area wells with a depth of 44" or greater will continue to have the option of a ladder. If a designer chooses to use steps, it is important safety feature to make sure that the occupants would be able to use those steps to evacuate from the window well.

The current provisions says ladders and steps don’t have to comply with the standard stairway provisions, however, while specific provisions are provided for ladders, no limits are provided for steps. The option here it the same width and distance between steps are permitted for ladders. The tread depth is the minimum width from alternating tread devices and ships ladders.

Following are examples of stepped configurations that are used today.

The Figure 1 and 2 are examples of stepped area wells that would comply with the proposed language.

![Figure 1](image-url)
Figure 2

Figure 3 and 4 are examples of stepped area wells that would **NOT** comply with the proposed language. The large changes in elevation would be difficult for a child or elderly person to negotiate on their own.

Figure 3
The following is the proposed language for areas wells associated with emergency escape and rescue openings.

**R310.5 Area wells.** An emergency escape and rescue opening with the bottom of the clear opening below the adjacent grade shall be provided with an area well in accordance with Sections R310.5.1 through R310.5.4.

**R310.5.1 Minimum size.** The horizontal area of the area well shall be not less than 9 square feet (0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area well shall allow the emergency escape and rescue opening to be fully opened.

Exception: The ladder or steps required by Section R310.5.2.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the area well.

**R310.5.2 Ladder and steps.** Area wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps. The ladder or steps shall not be obstructed by the emergency escape and rescue opening when the window or door is in the open position. Ladders or steps required by this section shall not be required to comply with Section R311.7.

**R310.5.2.1 Ladders.** Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center (o.c.) vertically for the full height of the area well.

**R310.5.2.2 Steps.** Steps shall have an inside width of at least 12 inches (305 mm), shall have minimum treads depth of 5 inches (127 mm) and a maximum riser height of 18 inches (457 mm) for the full height of the area well.

**R310.5.3 Drainage.** Area wells shall be designed for proper drainage by connecting to the building’s foundation drainage system required by Section R405.1.

Exception: A drainage system for area wells is not required where the foundation is on well-drained soil or sand gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

**R310.5.4 Bars, grilles, covers and screens.** Where bars, grilles, covers, screens or similar devices are placed over emergency escape and rescue openings, bulkhead enclosures, or area wells that serve such openings, the minimum net clear opening size shall comply with Sections R310.2 through R310.2.2 and R310.4.1. Such devices shall be releasable or removable from the inside without the use of a key or tool or force greater than that required for the normal operation of the escape and rescue opening.

This is one of a series of proposal to coordinate the requirements for emergency escape and rescue openings in the IBC and IRC. While independent issues, if all the proposals are approved, the IRC section would appear as indicated in the reason for the proposal to revise the definition – emergency escape and rescue openings. The IBC portion was E112-18(AS).
This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This is a design option for window wells that want to use steps instead of ladders.

Proposal # 4156

RB101-19
2018 International Residential Code

Revise as follows:

R310.6 Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing basements undergo alterations or repairs.

   Exception: New sleeping rooms, habitable spaces created in an existing basement shall be provided with emergency escape and rescue openings in accordance with Section R310.1.

Reason: This exception emphasizes the importance of providing an emergency escape and rescue opening (EERO) when sleeping rooms are added to existing basements. However, when a basement is altered to create habitable space, such as a living room or recreational room, many of the same risks will be encountered in an emergency. In addition, when a basement is reconfigured to create multiple rooms, those rooms may not remain for non-sleeping purposes. For example, if a basement office is later converted to a bedroom, owners will rarely seek a permit.

The intention of this code change is to increase the safety of basements when they are converted to habitable space and not just sleeping rooms. This code change would cause an owner to install an EERO when the alteration of a basement causes a basement to become habitable, which would include spaces used for living, sleeping, eating or cooking.

Cost Impact: The code change proposal will increase the cost of construction

This code change could increase the cost of construction due to EEROs being installed in habitable spaces rather than just sleeping rooms. If a basement was undergoing an alteration to create a habitable space other than a sleeping room, an EERO would now be required.
2018 International Residential Code

SECTION R311
MEANS OF EGRESS

Revise as follows:

R311.1 Means of egress. Dwellings shall be provided with a means of egress in accordance with this section. The means of egress shall provide a continuous and unobstructed path of vertical and horizontal egress travel from all portions of the dwelling to the required egress door public way without requiring travel through a garage. The required egress door shall open directly into a public way or to a yard or court that opens to a public way.

Reason: It is important to provide code compliance to the public way. This change provides consistency with the IBC and previous code editions which required compliance to the public way for residential uses.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Any fixture required to be constructed to the public way for example a stairway down a hill would already be needed.
2018 International Residential Code

Revise as follows:

R311.3.2 Floor elevations at other exterior doors. Doors, other than the required egress door, including doors required in Section R302.5.1, shall be provided with landings or floors not more than $7^{3/4}$ inches (196 mm) below the top of the threshold.

Exception: A top landing is not required where a stairway of not more than two risers is located on the exterior side of the door, provided that the door does not swing over the stairway.

Reason: Doors that are required to be installed per Section R302.5.1 often times have a threshold. Some builders feel that they are not required to measure their floor or landing to the top of the threshold because Section R311.3.2 is used for "other exterior doors". Since the doors are part of the building thermal envelope they would be considered exterior doors. This change would eliminate the confusion of this door meeting the requirements of Section R311.3.2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code requires a floor, landing, or stairs on each side of a door. This change addresses a location where doors that are used have a threshold the majority of the time. This section is addresses how the rise of a floor, landing or stair is to be measured when the door has a threshold. By adding this in the code it would cut down on the cost of rebuilding any landings or stairs that were constructed and the top of the threshold was not figured into the rise of the landing or stair.
Proponent: Shaunna Mozingo, City of Westminster, representing Self (smozingo@cityofwestminster.us)

2018 International Residential Code

Revise as follows:

[RB] STAIRWAY. One or more flights of stairs, either interior or exterior, with the necessary landings and connecting platforms to form a continuous and uninterrupted passage from one level to another within or attached to a building, porch or deck.

R311.4 Vertical egress. Egress from habitable levels including habitable attics and basements, and from one level to another within or attached to a building, porch or deck, that are not provided with an egress door in accordance with Section R311.2 shall be by a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

Reason: Does a stair from a deck have to comply with any code requirements? That depends on who you talk to.

R311 talks about residential means of egress and requires one means of egress from a dwelling unit. With stairway provisions included under MOE in 311, does that mean that only stairs for the required egress have to comply and all others do not? 1/3 of those questioned believe this.

The definition of a stairway was changed to include some scoping to show that it includes levels attached to or within the building or porch or deck. Since the definition includes that wording, 1/3 of the people polled believe that all stairs that attach to the building or are within the building must comply.

R311.4 Vertical egress specifically mentions vertical egress being required from habitable spaces and does not mention decks and porches so the last third believe that the requirement is only for stairs of habitable spaces that must comply.

This proposal takes the scoping language out of the IRC definition so that the definition now matches the IBC definition and we added the scoping into the vertical egress section so that the intent of the definition is actually realized in code language.

We would also ask that the word "stairway" be italicized throughout R311 to clear up some of this. We were initially going to just suggest this as the fix but many agreed that the scoping wording in the IRC definition needed to come out and be placed in the body of the code.

Cost Impact: The code change proposal will increase the cost of construction

ICC COMMITTEE ACTION HEARINGS :: April, 2019
Some people will say it increases cost because stairs that were not from habitable space never had to comply. Some will say that it will not increase cost because all stairs within or attached to the building had to always comply.

Proposal # 5583
2018 International Residential Code

Revise as follows:

R311.5 Landing, deck, balcony and stair construction and attachment. Exterior landings, decks, balconies, stairs and similar facilities shall be positively anchored to the primary structure to resist both vertical and lateral forces or shall be designed to be self-supporting. Attachment shall not be accomplished by use of toenails or nails subject to withdrawal. Balcony and stair construction shall be in accordance with Sections R311.5.1, R311.5.2 and R311.5.3.

Add new text as follows:

R311.5.1 Attachment. Landings, decks, balconies, stairs and similar facilities shall be positively anchored to the primary structure to resist both vertical and lateral forces or shall be designed to be self-supporting. Attachment shall not be accomplished by use of toenails or nails subject to withdrawal.

R311.5.2 Stair stringer support. Stair stringers shall be provided with bearing at the upper level for the full cut depth of the stringer against a header or the floor framing and shall be supported with a minimum 2X8 ledger nailed to each stud with 3-8d nails or an approved hanger installed in accordance with the manufacturer’s installation instructions.

Stair stringers shall be provided with support of the full cut depth of the stringer on the lower floor platform or other solid surface at the lower level of the stringer. The toe of the stringer shall be notched and a minimum 2X4 toe board shall be installed at the toe of the stringer in accordance with Figure R311.5.2. The stringer toe board shall be attached to the floor framing or solid blocking with a minimum of eight 16d nails or to a concrete surface with three ½ inch X 3 inch long anchor bolts.

R311.5.3 Stair stringer cutting and notching. A stringer that is cut or notched to form the stair treads and risers shall have a remaining uncut or notched throat depth not less than shown in Table R311.5.3.

<table>
<thead>
<tr>

TABLE R311.5.3
MINIMUM STAIR STRINGER THROAT DEPTH

TABLE R311.5.4 ALLOWABLE STAIR STRINGER SPAN
### Reason:
The International Residential Code has lack any minimum specifications for stairway construction. The proposed new code subsections removes the application of R311.5 from exterior locations only and adds some very basic construction guidelines to establish minimum requirements for attachment, support, cutting and notching and maximum spans of stairway stringers.

### Cost Impact:
The code change proposal will not increase or decrease the cost of construction. There should be little impact to the cost of construction as the proposed subsections only codify what are basic construction methodology.

---

---

![Diagram of stairway construction with text: Let-in 2x nailer. Use eight 16d sinker nails, staggered. Nail into framing members below. For concrete floors, fuse three 1/2" diameter X 3" long anchor bolts.](image-url)
[RB] STAIRWAY. One or more flights of stairs, either interior or exterior, with the necessary landings and connecting platforms to form a continuous and uninterrupted passage from one level to another within or attached to a building, porch or deck.

R311.7 Stairways. Where provided or required by this code, stairways shall comply with this section.

   Exception: stairways not within or attached to a building, porch or deck

R311.8 Ramps. Where provided or required by this code, ramps shall comply with this section.

   Exception: Ramps not within or attached to a building, porch or deck

Reason: Does a stair from a deck have to comply with any code requirements? That depends on who you talk to.
R311 talks about residential means of egress and requires one means of egress from a dwelling unit. With stairway provisions included under MOE in 311, does that mean that only stairs for the required egress have to comply and all others do not? 1/3 of those questioned believe this.

The definition of a stairway was changed to include some scoping to show that it includes levels attached to or within the building or porch or deck. Since the definition includes that wording, 1/3 of the people polled believe that all stairs that attach to the building or are within the building must comply.

R311.4 Vertical egress specifically mentions vertical egress being required from habitable spaces and doesn't mention decks and porches so the last third believe that the requirement is only for stairs of habitable spaces that must comply.

This proposal takes the scoping language out of the IRC definition so that the definition now matches the IBC definition and has added the scoping into the stairway and ramp sections so that the intent of the definition is actually realized in code language.

In CDP Access, R311.7 and8 are put in as sections instead of subsections so it wouldn't let us edit as you can a subsection so we hope you get the idea that the intent is to read as follows:

R311.7 Stairways. When provided or required by this code, stairways shall comply with this section.

   Exception: stairways not within or attached to a building, porch or deck

All remaining subsections of 311.7 unchanged. the same would work for ramps under r311.8.
We would also ask that the word "stairway" be italicized throughout R311 to clear up some of this. We were initially going to just suggest this as the fix but many agreed that the scoping wording in the IRC definition needed to come out and be placed in the body of the code.

**Cost Impact:** The code change proposal will increase the cost of construction
Some people will say it increases cost because stairs that were not from habitable space never had to comply.
some will say that it will not increase cost because all stairs within or attached to the building had to always comply.

Proposal # 5597

RB107-19
Proponent: David Cooper, Stair Manufacturing and Design Consultants, representing Stairbuilders and Manufacturers Association (coderep@stairways.org)

2018 International Residential Code

Revise as follows:

R311.7.1 Width. Stairways shall be not less than 36 inches (914 mm) in clear width at all points above the permitted handrail height and below the required headroom height. The clear width of stairways at and below the handrail height, including treads and landings, shall be not less than 31\(\frac{1}{2}\) inches (787 mm) where a handrail is installed on one side and 27 inches (698 mm) where handrails are installed on both sides. Baseboards and skirtboards shall not project into the clear width of the stairway, as measured above the handrails, more than 4\(\frac{1}{2}\) inches (114 mm) on either side of the stairway. At the sides of stairs with guards that are open above the handrail height the projection shall be measured horizontally from the inside edge of the top of the guard.

Exception: The width of spiral stairways shall be in accordance with Section R311.7.10.1.

Reason: The allowed projection of trim into the width of a stairway is not clearly addressed in the code. Although discussed in the commentary, certain accepted practices that are prevalent in residential stairways are not clarified and often inconsistently interpreted. Further issues arise from the fact that the maximum projection of trim components is not defined in the code.

1. This code change specifically addresses only baseboard at landings and skirtboards at the side of flights.
2. The proposal defines a maximum projection of 4.5 inches that matches that allowed for handrails in R311.7.8.2 Handrail projection.
3. This code change does not change any of the current minimum stairway widths.
4. The projection of baseboard and skirtboards is measured related to the stairway width as determined at the location "above the handrails". This prevents reduction of the minimum widths currently stated "at and below the handrails" by the baseboards and skirtboards.
5. Where the open side of a stairway has a guard and there is no surface to establish a width above the handrails, the projection of the baseboard and skirtboard are measured from the inside edge of the top of the guard. This is important to allow consistent enforcement of what is the most common, cost-effective style of guards used in one and two family homes. Please see Photos 1 - 3 illustrating this style of guard and the necessary projection of the skirtboard. Note how the balusters terminate in the top of the wall and the skirtboard projects into the stairway. This type of guard system is highly utilized because it is easily adapted to low cost carpeted stairways.
6. Please see photo 4 illustrating the measurement of the projection at a guard.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. Although more pervasive use of carpeted stairs with "curb" or "wall cap" guard systems would reduce costs over
finished hardwood stairs and guards it is not possible to estimate.

Proposal # 5216

RB108-19
2018 International Residential Code

R311.4 Vertical egress. Egress from habitable levels including habitable attics and basements that are not provided with an egress door in accordance with Section R311.2 shall be by a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7. Stairways serving attics that do not contain habitable space are not required to meet the requirements of Section R311.7.

Reason: The IRC Contains some Means of Egress requirements, but does not address some constructions that fall outside of exit and egress. The code requires stairways to comply with a series of requirements for landings, stair tread and rise, handrailes, headroom etc. Attics that are not habitable spaces and are thus unoccupiable should be exempt from stairway requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal is consistent with current practice.
Proponent: Jenifer Gilliland, representing Department of Construction and Inspections
(jenifer.gilliland@seattle.gov)

2018 International Residential Code

Revise as follows:

R311.7.3 Vertical rise. A flight of stairs shall not have a vertical rise greater than 12 feet 7 inches (3835 mm) between floor levels or landings.

Reason: The notation in the code change uses feet and inches to describe the vertical rise of a flight of stairs rather than just inches. This change aligns the format of this section of code with other portions of the code (see section 305 requirements) and is easier for readers to apply.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is just a change in the formatting of feet and inches in this section of the code.
RB111-19
IRC®: R311.7.5.1

Proponent: David Cooper, representing Stairbuilders and Manufacturers Association (coderep@stairways.org)

2018 International Residential Code

Revise as follows:

R311.7.5.1 Risers. The riser height shall be not more than $7^{3/4}$ inches (196 mm). The riser height shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than $3/8$ inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. At open risers, openings located more than 30 inches (762 mm), as measured vertically, to the floor or grade below shall not permit the passage of a 4-inch-diameter (102 mm) sphere.

Exceptions:

1. The opening between adjacent treads is not limited on spiral stairways.
2. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1.

Reason: -

Riser or Riser Height:

It is necessary to insert the word height in the second sentence to more clearly state what is being measured. In most cases the riser or more accurately the face of the riser terminates under the tread above and is not the subject of the measurement described. The dimension of the "riser" would be less than the "riser height". There are also instances where there is "no riser" but there is still a riser height, referred to in this section as "open risers". This change would add help to explain that riser a defined term in the IRC is different than "riser height" and aid in the correct application of the code.

Deletion of the Maximum Angle Reference:

The entire phrase - "at an angle not more than 30 degrees (0.51 rad) from the vertical" has been deleted. It is simply unnecessary and only creates confusion.

It is unnecessary to have a maximum angle limit because the maximum nosing projection of 1.25 inches as stated in R311.7.5.3 limits the maximum angle of the riser. See figures 1 and 2 illustrating the angle of the riser slope of typical "slant riser" stairs with the maximum nosing projection.

1. Figure 1 illustrates that the maximum angle of 17 degrees can be obtained in one plane with a 4 inch riser height
2. Figure 2 illustrates that the maximum angle of 10 degrees can be obtained in one plane with a 7 inch riser height

From these two illustrations it is easy to see both the taller riser heights and shorter nosing projections allowed will produce even lower angles. The illustrations prove that the angle of the riser is controlled by the projection of the tread nosing. I have not illustrated shorter riser heights but the angle would not exceed 30 degrees until you approached the implausible riser height of 2 inches.
A similar change was introduced to the IBC in this cycle. There was great confusion over what is a riser and what is a tread nosing. There was concern that eliminating the maximum angle reference would restrict the use of curves or multiple slopes as shown in the A117.1-2017 NOSING Figures, Fig. 504.5B and Fig. 504.5C. That is not the case in the IRC. In the IRC, riser is defined as, Riser. 1. The vertical component of a step or stair., and tread and landing nosings are regulated in R311.7.5.3 Nosings.

Neither the A117.1 nosing profiles shown here nor those commonly used nosing details as regulated by R311.7.5.3 Nosings will be affected by this change. Only a clarity of the regulation, and a better understanding of the design options currently allowed in the code will result.
Cost Impact: The code change proposal will not increase or decrease the cost of construction.
This change does not effect the methods or materials and only offers clarification of the code.

Proposal # 5261

RB111-19
R311.7.5.1 Risers. The riser height shall be not more than $\frac{7}{2} \text{ inches (196.180 mm)}$. The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than $\frac{3}{8} \text{ inch (9.5 mm)}$. Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees ($0.51 \text{ rad}$) from the vertical. At open risers, openings located more than 30 inches (762 mm), as measured vertically, to the floor or grade below shall not permit the passage of a 4-inch-diameter (102 mm) sphere.

Exceptions:

1. The opening between adjacent treads is not limited on spiral stairways.
2. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.5.2 Treads. The tread depth shall be not less than 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread’s leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than $\frac{3}{8} \text{ inch (9.5 mm)}$.

R311.7.5.2.1 Winder treads. Winder treads shall have a tread depth of not less than 11 inches (280 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a tread depth of not less than 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than $\frac{3}{8} \text{ inch (9.5 mm)}$. Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and shall not be required to be within $\frac{3}{8} \text{ inch (9.5 mm)}$ of the rectangular tread depth.

Exception: The tread depth at spiral stairways shall be in accordance with Section R311.7.10.1.

Reason: This proposal shares the Reason Statement for Proposal 5467, which includes the changes proposed on the step rise and tread depth — changing 7.75 inches for the maximum rise to 7 inches and changing the minimum tread depth from 10 inches to 11 inches in Sections R311.7.5.1, R311.7.5.2 and R311.7.5.2.1. Proposal 5467 accomplishes the same change indirectly by deleting almost all the requirements of R311.7 and requiring that stairs comply with NFPA 101-2018 which has the "7-11" requirement applying to dwelling unit stairs (with an exception for certain spiral stairs for which more options are provided in NFPA 101 than in the IRC). Those interested in this proposal should refer to the Reason Statement for Proposal 5467 dealing with all of R311.7. The bottom line is that if the "7-11" rule is applied (as it has for two decades for all other stairs in the IBC) and the dangers of injuries on stairways are mostly in homes, that is where the "7-11" should also be required. The Reason Statement provides very extensive technical and other information that directly confirms the much better performance of the "7-11" geometry relative to the several times more dangerous step dimensions — including the 7.75 - 10 geometry — that have been used in homes where about 90 percent of the stair-related falls occur in the US at a huge cost to everybody — currently on the order of $100 billion dollars annually in societal injury costs in the USA.

Bibliography: A few publication are cited in the Reason Statement for my Proposal # 5467 and nothing beyond
those is needed for this more-limited proposal.

**Cost Impact:** The code change proposal will increase the cost of construction
While cost of construction will increase, that increase (as shown also in the first proposal on this same topic in a 2003 proposal on stairways in the IRC) pales in comparison to the benefits of the "7-11" step geometry for dwelling unit stairs.

From the Reason Statement (which is the Reason Statement for Proposal 5467) covering all of R311, not just rise and tread depth changes, comes the following updated detail on cost impact in relation to step dimensions.

"If we assume, as an approximation, there were about 120 million US households in 2012 (the midpoint in the periods discussed above) and further assume an average of one flight of stairs for each household (with some homes having several flights of stairs and many having none), the average cost of home stairway-related injuries is roughly $700 per stair flight (or household) per year. This average injury cost greatly exceeds the annual cost (e.g., over a 50-year service life) of a stair flight in a home. As currently allowed by the IRC and built into new homes, stairways with such high annual injury costs are an extremely poor investment in terms of costs to society, families and individuals."

Proposal # 5412

RB112-19
2018 International Residential Code

Revise as follows:

R311.7.7 Stairway walking surface. The walking surface of treads and landings of stairways shall be sloped not steeper than one unit vertical in 48 units horizontal (2-percent slope).

   Exception: Where the surface of a landing is required elsewhere in the code to drain surface water, the walking surface of the landing shall be sloped not steeper than 1 unit vertical in 20 units horizontal (5-percent slope) in the direction of travel.

Reason: Landings have been required in more places since the 2009 IRC defined a single riser as a “stair.” This causes difficulties where the MAXIMUM landing slope requirements of R311.7.7 conflict with the MINIMUM drainage slope requirements in the exception of R401.3 (reprinted below).

The picture below shows an example of such a landing. If one or more risers lead from the raised walkway to the paved driveway the landing provision would require a MAX slope of 2 percent in either direction. But the drainage provision in R401.3 would require a MIN slope of 2 percent away from the building. These dueling requirements create a condition that is not exactly a conflict, but it is just as impossible to satisfy them both. The 5-percent slope in the exception was chosen to correlate with the maximum running slope allowed for an accessible route.

Additionally, the word “inches” was changed to “units” for consistency. (See definition of ramp, Section R311.3, R311.8, etc.)
R401.3 Drainage. Surface drainage shall be diverted to a storm sewer conveyance or other approved point of collection that does not create a hazard. Lots shall be graded to drain surface water away from foundation walls. The grade shall fall not fewer than 6 inches (152 mm) within the first 10 feet (3048 mm).

Exception: Where lot lines, walls, slopes or other physical barriers prohibit 6 inches (152 mm) of fall within 10 feet (3048 mm), drains or swales shall be constructed to ensure drainage away from the structure. Impervious surfaces within 10 feet (3048 mm) of the building foundation shall be sloped not less than 2 percent away from the building.

R309.1 Floor surface. Garage floor surfaces shall be of approved noncombustible material. The area of floor used for parking of automobiles or other vehicles shall be sloped to facilitate the movement of liquids to a drain or toward the main vehicle entry doorway.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed change removes the impossible-to-meet requirements for drainage and slope when they both apply to a landing. If anything it would decrease the cost of construction due to failed inspections.
RB114-19

IRC®: R311.7.8.4 (New)

Proponent: Lucas Pump, City of Cedar Rapids, representing Self (l.pump@cedar-rapids.org)

2018 International Residential Code

Revise as follows:

R311.7.8.4 Continuity. Handrails shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals.

Exceptions:

1. Handrail continuity shall be permitted to be interrupted by a newel post at a turn in a flight with winders, at a landing, or over the lowest tread.
2. A volute, turnout or starting easing shall be allowed to terminate over the lowest tread.
3. Offsets or interruptions of six inches or less in total length shall be considered to be continuous.

Reason: This proposal would allow a handrail to terminate at a newel post or a wall section, then start back up. Also, this would allow for more aesthetically pleasing handrail designs, in a residential stairway were wall sections are off-set and would allow for a newel post within the handrail.
Cost Impact: The code change proposal will decrease the cost of construction.
This proposal would decrease the cost of construction because the contractor could eliminate the need for some of the handrail offset fittings and elbows.

Proposal # 3881

RB114-19
**RB115-19**

**IRC®: R311.7.8.4**

**Proponent:** Stephen Thomas, Colorado Code Consulting, LLC, representing Himself (sthomas@coloradocode.net)

**2018 International Residential Code**

Revise as follows:

**R311.7.8.4 Continuity.** Handrails shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals.

**Exceptions:**

1. Handrail continuity shall be permitted to be interrupted by a newel post at a turn in a flight with winders, at a landing, or over the lowest tread.
2. A volute, turnout or starting easing shall be allowed to terminate over the lowest tread.

**Reason:** The term safety terminal is for commercial handrails that need to comply with the projecting elements requirements for the means of egress and accessibility. It is also not a defined term in the IRC. Many people don't know what a safety terminal is. Therefore, the language is not needed in the IRC and should be deleted.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal will have not an impact on the construction. It is deleting language that is not needed in the IRC.

Proposal # 5497
R311.7
Stairways.

Revise as follows:

R311.7.1 Width. Stairways. Stairways shall be not less than 36 inches (914 mm) in clear width at all points above the permitted handrail height and below the required headroom height. The clear width of stairways at and below the handrail height, including treads and landings, shall be not less than 31\(\frac{1}{2}\) inches (787 mm) where a handrail is installed on one side and 27 inches (698 mm) where handrails are installed on both sides.

Exception: The width of spiral stairways shall be in accordance with Section R311.7.10.1.

comply with NFPA 101-2018 Section 24.2.5.

Delete without substitution:

R311.7.2 Headroom. The headroom in stairways shall be not less than 6 feet 8 inches (2032 mm) measured vertically from the sloped line adjoining the tread nosing or from the floor surface of the landing or platform on that portion of the stairway:

Exceptions:

1. Where the nosings of treads at the side of a flight extend under the edge of a floor opening through which the stair passes, the floor opening shall not project horizontally into the required headroom more than 4\(\frac{1}{4}\) inches (121 mm).

2. The headroom for spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.3 Vertical rise. A flight of stairs shall not have a vertical rise larger than 151 inches (3835 mm) between floor levels or landings.

R311.7.4 Walkline. The walkline across winder treads and landings shall be concentric to the turn and parallel to the direction of travel entering and exiting the turn. The walkline shall be located 12 inches (305 mm) from the inside of the turn. The 12-inch (305 mm) dimension shall be measured from the widest point of the clear stair width at the walking surface. Where winders are adjacent within a flight, the point of the widest clear stair width of the adjacent winders shall be used.

R311.7.5 Stair treads and risers. Stair treads and risers shall meet the requirements of this section. For the purposes of this section, dimensions and dimensioned surfaces shall be exclusive of carpets, rugs or runners.

R311.7.5.1 Risers. The riser height shall be not more than 7\(\frac{3}{4}\) inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than 8\(\frac{1}{2}\) inches (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. At open risers;
openings located more than 30 inches (762 mm), as measured vertically, to the floor or grade below shall not permit the passage of a 4-inch-diameter (102 mm) sphere.

**Exceptions:**

1. The opening between adjacent treads is not limited on spiral stairways.
2. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1.

**R311.7.5.2 Treads.** The tread depth shall be not less than 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread’s leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than 3/32 inch (9.5 mm).

**R311.7.5.2.1 Winder treads.** Winder treads shall have a tread depth of not less than 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a tread depth of not less than 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/32 inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and shall not be required to be within 3/32 inch (9.5 mm) of the rectangular tread depth.

**Exception:** The tread depth at spiral stairways shall be in accordance with Section R311.7.10.1.

**R311.7.5.3 Nosings.** Nosings at treads, landings and floors of stairways shall have a radius of curvature at the nosing not greater than 3/8 inch (14 mm) or a bevel not greater than 3/16 inch (12.7 mm). A nosing projection not less than 3/8 inch (19 mm) and not more than 1 3/4 inches (32 mm) shall be provided on stairways. The greatest nosing projection shall not exceed the smallest nosing projection by more than 3/32 inch (9.5 mm) within a stairway.

**Exception:** A nosing projection is not required where the tread depth is not less than 11 inches (279 mm).

Revise as follows:

**R311.7.5.4 Exterior plastic composite stair treads.** Plastic composite exterior stair treads shall comply with the provisions of this section and Section R507.2.2.

Delete without substitution:

**R311.7.6 Landings for stairways.** There shall be a floor or landing at the top and bottom of each stairway. The width perpendicular to the direction of travel shall be not less than the width of the flight served. For landings of shapes other than square or rectangular, the depth at the walk line and the total area shall be not less than that of a quarter circle with a radius equal to the required landing width. Where the stairway has a straight run, the depth in the direction of travel shall be not less than 36 inches (914 mm).

**Exception:** A floor or landing is not required at the top of an interior flight of stairs, including stairs in an enclosed garage, provided that a door does not swing over the stairs.

**R311.7.7 Stairway walking surface.** The walking surface of treads and landings of stairways shall be sloped not steeper than one unit vertical in 48 inches horizontal (2-percent slope).

**R311.7.8 Handrails.** Handrails shall be provided on not less than one side of each flight of stairs with four or more risers.

**R311.7.8.1 Height.** Handrail height, measured vertically from the sloped plane adjoining the tread nosing, or
finish surface of ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

**Exceptions:**

1. The use of a volute, turnout or starting easing shall be allowed over the lowest tread.
2. Where handrail fittings or bendings are used to provide continuous transition between flights; transitions at winder treads, the transition from handrail to guard; or used at the start of a flight, the handrail height at the fittings or bendings shall be permitted to exceed 38 inches (956 mm).

**R311.7.8.2 Handrail projection.** Handrails shall not project more than 4\(\frac{1}{2}\) inches (114 mm) on either side of the stairway.

**Exception:** Where nosings of landings, floors or passing flights project into the stairway reducing the clearance at passing handrails, handrails shall project not more than 6\(\frac{3}{4}\) inches (165 mm) into the stairway, provided that the stair width and handrail clearance are not reduced to less than that required.

**R311.7.8.3 Handrail clearance.** Handrails adjacent to a wall shall have a space of not less than 1\(\frac{1}{4}\) inches (38 mm) between the wall and the handrails.

**R311.7.8.4 Continuity.** Handrails shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals.

**Exceptions:**

1. Handrail continuity shall be permitted to be interrupted by a newel post at a turn in a flight with winders, at a landing, or over the lowest tread.
2. A volute, turnout or starting easing shall be allowed to terminate over the lowest tread.

**R311.7.8.5 Grip size.** Required handrails shall be of one of the following types or provide equivalent graspability:

1. Type I. Handrails with a circular cross section shall have an outside diameter of not less than 4\(\frac{1}{4}\) inches (32 mm) and not greater than 2 inches (51 mm). If the handrail is not circular, it shall have a perimeter of not less than 4 inches (102 mm) and not greater than 6\(\frac{3}{4}\) inches (160 mm) and a cross section of not more than 2\(\frac{3}{4}\) inches (57 mm). Edges shall have a radius of not less than \(0.01\) inch (0.25 mm).

2. Type II. Handrails with a perimeter greater than 6\(\frac{1}{4}\) inches (160 mm) shall have a graspable finger recess area on both sides of the profile. The finger recess shall begin within \(\frac{3}{4}\) inch (19 mm) measured vertically from the tallest portion of the profile and have a depth of not less than \(\frac{5}{16}\) inch (8 mm) within \(\frac{3}{8}\) inch (22 mm) below the widest portion of the profile. This required depth shall continue for not less than \(\frac{3}{8}\) inch (10 mm) to a level that is not less than 4\(\frac{3}{4}\) inches (45 mm) below the tallest portion of the profile. The width of the handrail above the recess shall be not less than 1\(\frac{3}{4}\) inches (32 mm) and not more than 2\(\frac{3}{4}\) inches (70 mm). Edges shall have a radius of not less than \(0.01\) inch (0.25 mm).

**Revise as follows:**

**R311.7.8.6 R311.7.3 Exterior plastic composite handrails.** Plastic composite exterior handrails shall comply with the requirements of Section R507.2.2.
R311.7.9.4 Illumination. Stairways shall be provided with illumination in accordance with Sections R303.7 and R303.8. The illumination system shall be capable of providing a minimum of 10 foot-candles (110 lux), measured at the center of stairway landings and treads, when the stairway is in use.

R311.7.10.5 Special stairways. Spiral stairways and bulkhead enclosure stairways shall comply with the requirements of Section R311.7 except as specified in Sections R311.7.10.1 and R311.7.10.2.

Delete without substitution:

R311.7-10.1 Spiral stairways. The clear width at and below the handrails at spiral stairways shall be not less than 26 inches (660 mm) and the walkline radius shall be not greater than 24\(\frac{1}{2}\) inches (622 mm). Each tread shall have a depth of not less than 6\(\frac{1}{4}\) inches (171 mm) at the walkline. Treads shall be identical, and the rise shall be not more than 9\(\frac{1}{2}\) inches (241 mm). Headroom shall be not less than 6 feet 6 inches (1982 mm).

R311.7-10.2 Bulkhead enclosure stairways. Stairways serving bulkhead enclosures, not part of the required building egress, providing access from the outside grade level to the basement shall be exempt from the requirements of Sections R311.3 and R311.7 where the height from the basement finished floor level to grade adjacent to the stairway is not more than 8 feet (2438 mm) and the grade level opening to the stairway is covered by a bulkhead enclosure with hinged doors or other approved means.

Revise as follows:

R311.7-11.6 Alternating tread devices. Alternating tread devices shall not be used as an element of a means of egress. Alternating tread devices shall be permitted provided that a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required.

The clear width at and below the handrails shall be not less than 20 inches (508 mm).

Exception: Alternating tread devices are allowed to be used as an element of a means of egress for lofts, mezzanines and similar areas of 200 gross square feet (18.6 m²) or less where such devices do not provide exclusive access to a kitchen or bathroom.

R311.7-11.6.1 Treads of alternating tread devices. Alternating tread devices shall have a tread depth of not less than 5 inches (127 mm), a projected tread depth of not less than 8\(\frac{1}{2}\) inches (216 mm), a tread width of not less than 7 inches (178 mm) and a riser height of not more than 9\(\frac{1}{2}\) inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial tread of the device shall begin at the same elevation as the platform, landing or floor surface.

R311.7-11.6.2 Handrails of alternating tread devices. Handrails shall be provided on both sides of alternating tread devices and shall comply with Sections R311.7.8.2 to R311.7.8.6. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

R311.7-14 Ships ladders. Ships ladders shall not be used as an element of a means of egress. Ships ladders shall be permitted provided that a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches.

Exception: Ships ladders are allowed to be used as an element of a means of egress for lofts, mezzanines and similar areas of 200 gross square feet (18.6 m²) or less that do not provide exclusive access to a kitchen or bathroom.
R311.7.12.1 Treads of ships ladders. Treads shall have a depth of not less than 5 inches (127 mm). The tread shall be projected such that the total of the tread depth plus the nosing projection is not less than 8 1/2 inches (216 mm). The riser height shall be not more than 9 1/2 inches (241 mm).

R311.7.12.2 Handrails of ships ladders. Handrails shall be provided on both sides of ships ladders and shall comply with Sections R311.7.8.2 to R311.7.8.6. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm). Section R311.7.1.

Reason: Introduction. Over the last two decades, covering the entire history of the International Residential Code, subsection R311.7 on stairways—which started with some serious defects—has not improved as much as warranted by the home stair-related injury toll, especially the toll's growth over the last two decades. This proponent sees little value in addressing, in detail, all of the IRC's deficits with regards to stairways unless there are major changes in how ICC members and committees understand and address the overarching topic of home step dimensions, handrail requirements, etc., with step dimensions being the most potent set of factors impacting both home stairway usability and safety. Thus the best strategy is to propose a substitution of most of the IRC's stairway requirements with a reference to NFPA 101's Chapter on One and Two-Family Dwellings. The justification for this drastic proposal is technical as well as procedural, with emphasis below on the technical issues. Addressing the procedural issues would mean going into detail on the overarching role of two organizations in the development, to date, of the IRC's stairway requirements, namely the National Association of Home Builders (NAHB) and the Stairway Manufacturers Association (SMA).

Neither of these organizations have been participating actively in all the research conducted over the last five decades in several countries, most notable of which are the USA, the UK, Japan and Canada. Such participation clearly sets the proponent of this substitution apart from the NAHB and SMA, both organizationally and in terms of any individual in these organizations (now and in the past three decades).

The proponent’s participation entails formal research (for 20 years at the National Research Council of Canada), international consulting (for four decades), ergonomics certification (since 1993, with re-certifications in 2010 and 2015), and public health involvement (as the lead, formal/voting representative for the American Public Health Association, APHA, on eight ICC and NFPA committees dating back two decades). His publications record includes about 100 publications on stairway use, safety and design. His record of formal presentations worldwide includes over 100 on stairways beginning in 1974. His record production of educational and documentary videos include over 30 videos and one documentary film, “The Stair Event” (the only such film on stairways, produced 40 years ago).

No individual, organization or any collection of these, can match the proponent’s record of scientific and technical accomplishments since 1967 which has resulted in several awards and an Honorary Doctor of Science degree. These reflect international recognition focused most intensively in three countries, the USA (his longest base of activity), Canada and the UK.

Moreover, the proponent is relatively well known by premises liability attorneys in the US and Canada who represent persons injured on stairways or, in a minority of cases, attorneys representing premises owners and operators. Some of the latter, rather than being defendants, are corporate counsel for very large organizations with multiple facilities where stairway safety has been a major concern and the organization wishes to take a pro-active approach to injury prevention. In Canada, due to the premises liability laws there, the proponent’s litigation-related work focuses much more on one- and two-family dwellings than is the case in the USA where the home stairway dangers are almost as bad as in Canada—especially in relation to stair step dimensions, but there has been less litigation focused on the comparable dangers to stairway users.

Bottom line: much has been learned over the last four decades especially that draws on multiple sources of insight on the real dangers of stairways and the need for model code organizations, adopting authorities and
enforcing officials to recognize just how devastating the home stairway-related injury *endemic* has become. Only NFPA has responded realistically to the home stairway-related endemic. ICC has had the opportunity to do so over the last 20 years but it has failed, very badly, to respond to the public health and safety situation. *This has to change!*

**Analogy connecting stairways and automobiles.** For readers who are put off by technical and other details, please read the following sentences about an apt comparison. Imagine the outcry that would have occurred if, starting decades ago, the automobile industry adopted, and implemented, a policy of only providing brakes for vehicles that were only used by relatively fit, working-age adults. For everyone else—e.g., children and older adults—vehicles would not be provided with functional brakes or steering that worked reliably for people with widely varying strength abilities. Of course the automobile industry—internationally (partly following developments in the USA)—took a different path, a path to cars that were not only safer, for example with brakes and steering systems, but were much more functional. These and other systems served a wide range of drivers and occupants in ALL use conditions, not only crashes, emergency stopping and control but for normal operational usability.

Through the decades, while the automobile industry adopted more progressive policies—*partly dictated by laws and regulations*—the building industry has steadfastly avoided clear evidence that home stairway-related falls were growing faster than population growth and costs of stair-related injuries vastly exceeded the initial costs of stairway construction. Indeed the building industry operated oblivious of scientific knowledge and other evidence.

**APHA Policies on Building Codes.** Since the turn of the century, ICC has diverged from NFPA’s far more evidence-based approach to ALL stairways, notably those in homes, as well as repeated public policies adopted by the American Public Health Association (APHA).

APHA Policy Statement 99-16, Public Health Role of Codes Regulating the Design, Construction and Use of Buildings

APHA Policy Statement 2000-19, Public Health Role of the National Fire Protection Association in Setting Codes and Standards for the Built Environment

APHA Policy Statement 200913, Building Code Development, Adoption, and Enforcement Problems Affecting Injury Prevention in, and Usability of, Homes and Other Buildings.

Here is what the last in this series, the currently active APHA policy 200913, stated:

"From ICC’s beginnings, there were indications that public health was not as high of a priority for the ICC, as was a dominating business presence in the US building regulatory field. This concern regarding the relationship between the ICC and the National Association of Home Builders (NAHB) was first addressed in APHA Policy 99-16 and reiterated in APHA Policy 2000-19. When the longer-established National Fire Protection Association (NFPA), with its very large set of widely used safety standards, decided to develop a competing model building code, APHA adopted policy statement 2000-19 to help influence NFPA in a more public health–oriented approach to model building code development. . . .

Much of what was recommended to NFPA in APHA’s policy 2000-19 was implemented in NFPA codes and standards during the next several years, including, in 2003, mainstreamed safety and usability requirements for the most dangerous element in homes, the stairways. . . ."
The model code development process, especially within ICC’s system of public hearings, is based on a model encouraging adversarial testimony and other formal input to the process. Certain issues typically pit advocates for public health goals (such as safety and accessibility or usability of the built environment) against certain industry representatives whose goals are to have little or no change in established, traditional practices; to experience minimal regulatory interference; and to claim often that housing affordability will be harmed.

As a general rule, there is no epidemiological or etiological basis for the traditional double, lower standard for home stair step geometry or for inferior handrail provision or functional quality; this was a point made explicitly in APHA’s Policy 2000-19. NFPA has taken this issue to heart in its post-2000 revisions to its leading codes; ICC has gone in the opposite direction, increasing the gulf of safety and usability levels between home stairways and those in other settings.

Therefore the APHA recommends:

5. ICC and NFPA should develop and maintain model codes and standards requiring home stairways to be designed and constructed so that stairs and railings provide at least the same level of usability and safety from falls as do stairs and railings in other buildings.”

Now, almost two decades after ICC published first editions of the IBC and IRC, ICC continues to ignore the evidence of stairway safety issues as well as the formally adopted policies of the American Public Health Association, APHA. Here follow highlights of that evidence, including Injury Epidemiology and Etiology.

Injury Epidemiology

Stairways. Since 2002, approximately the time that the IRC began to influence home stairway construction, medically-treated injuries in all settings—sufficient to lead to hospital emergency room visits—increased by about 39 percent as of 2017 in the USA. (This equates to a growth rate of about 2 percent a year over the 15-year period.) During this 15-year period, US population only increased by about 13 percent, that is with a demographic growth only about one-third that of stair-related injuries.

Also during this period there appears to have been an increase in the proportion of stairway related injuries occurring in home settings for which the location data are not as complete. For known locations, the home-based proportion has increased from about 85 percent to about 90 percent or higher over the 15-year period.

Stairs Compared to Fires. During this same 15-year period, fire-related fatalities in all US settings—with homes again being the most common site of fatalities—decreased with the approximate rate, per 100,000 population dropping from about 1.3 to about 0.98 injuries annually per 100,000 US population. Comparison of stair-related injuries with fire-related injuries is complicated by the lack of detail about the nature of treatment needed for the fire-related injuries. For stair-related injuries, that are professionally treated, the treatment rates per 100,000 US population are displayed in Table 1 for the annual averages over the years 2010 to 2014: the average injury rate was about 1,400 per 100,000 population. At about the same time, fire-related injuries (based on 2016 figures from the US Fire Administration) had a rate of about 45 injuries per 100,000 and they were declining. (The resulting ratio of stairways to fire is about 31, a factor depicted in Figure 1.) There were some age differences for fires with rates of 55 for middle-age adults, 25 for children and 45 for older adults, all per 100,000 population. By contrast, during the period 2010-2014, annual rates for stair-related injuries, per 100,000 population, that resulted in professional medical care, are described in more detail in Table 1, right to left: for Doctors Offices or Outpatient Clinics, for Emergency Departments, and for Hospital Admission.

Table 1. Annual US Injury Rates for Stairs
(per 100,000 population), by treatment and age, during 2010-2014
(Source: Pacific Institute for Research and Evaluation, Maryland)

Comparing these stairway-related rates, with their enhanced specificity, in Table 1, with those noted earlier for fires, we should note the much larger public safety problem posed by stairways, compared to fires. From Figure 1 we should recognize that there is great disparity of code response to injury occurrence for stairways, along with other common dangers.
with another badly neglected topic in the IRC, fall prevention for bathtubs and showers (the subject of another set of proposed changes to the IRC).

To fully appreciate the size of the stairway safety problem in the USA, Table 2 provides estimates of incidence, annually, of injuries by treatment type and victim age.

Table 2. Annual US Injury Incidence for Stairs
by treatment and age, during 2010-2014
(Source: Pacific Institute for Research and Evaluation, Maryland)

The overall total, of over 4 million professionally treated injuries annually in the USA (within the period, 2010-2014), related to stairways, is mind blowing as is the huge societal cost of such injuries. During 2010-2014, the average annual societal cost of stairway-related injuries in the USA was estimated as over $92 billion (2009 US dollars) and the vast majority of those injuries were in homes. (Source: Lawrence, B., Spicer, R., Miller, T. A fresh look at the costs of non-fatal consumer product injuries. Injury Prevention, digital publication, August 2014, paper journal publication, 2015:21:23-29.0)

Some Preliminary Cost-Benefit Insights. If we assume, as an approximation, there were about 120 million US households in 2012 (the midpoint in the periods discussed above) and further assume an average of one flight of stairs for each household (with some homes having several flights of stairs and many having none), the average cost of home stairway-related injuries is roughly $700 per stair flight (or household) per year. This average injury cost greatly exceeds the annual cost (e.g., over a 50-year service life) of a stair flight in a home. As currently allowed by the IRC and built into new homes, stairways with such high annual injury costs are an extremely poor investment in terms of costs to society, families and individuals. Why this is the case is discussed in the next section, on etiology, the study of causes (of bad events such as disease, injuries, etc.).

Injury Etiology for Stairways
There is widespread agreement—about the very prominent, indeed central role of stair step dimensions (among several stairway design and construction factors)—among all the experts on stairway safety who have researched the topic and have been lead authors of papers, book chapters, a book or producer of widely viewed, edited video programs. Many have worked at, or for, the leading building science and technology centers in Japan, Britain, Australia, Sweden, Canada and the USA during the last six decades. All of the following individuals, listed alphabetically, have addressed various aspects of stairway use, safety and design; all have published authoritatively on one or more of these topics. Most have had long-term contact with the proponent. All favor improvements in stairway design to reduce the toll of injuries seen internationally over the last several decades.

Both Sides of the “7-11” Proposal for Home Stairs Debated. There are relatively few people who have argued on the reactionary, industry side of the long-running debate about improving the design of stairways. One published example of an extended debate on the topic of improved home step dimensions dates back to 1985 (Dacquisto, D.J. and Pauls, J., 1985, The “7-11” stair: Should it be required for residential construction? The Building Official and Code Administrator, May-June, pp. 16-35.) David Dacquisto represented the National Association of Home Builders in this published debate. Jake Pauls represented scientific plus technical perspectives, e.g., based on research and public health evidence. The “Yes” side of published, 12-page account of the debate, in the BOCA magazine, was based on an 8,000-word position paper by Pauls.

Here follow concluding remarks in both sides’ lengthy arguments, with Pauls’ remarks selected for roughly comparable length and subject focus:
Dacquisto, for the NAHB. “What should be the standard for deciding whether to adopt a code proposal which faces opposition? Both cost and benefit estimates will always be uncertain. A suggested minimum standard is that no regulatory proposal should be finally approved over opposition unless the regulatory body finds it more likely than not that benefits of the proposal will exceed the costs, and believes there is probably no less costly way to achieve the anticipated benefits. The burden of proof should be on the proponent. By this standard, for the reasons presented in this article, the residential 7/11 stair proposal appears unwarranted at the present time.”

Pauls, for many experts and consumers “. . . Clearly, judging from the technical literature, the disagreement among apparently, "reasonable people" is certainly not great enough to give any real comfort to those trying to justify continuation of very poor step geometry standards for residential stairs. Also, despite Mr. Dacquisto's apparent attempts to conceal the fact, literature produced by "reasonable people" generally calls for residential stair geometry that is similar to and sometimes better than, what is expected elsewhere. . . .”

Today, over three decades after the above debate, the evidence has grown significantly, both from epidemiology and etiology, for improving home step dimensions, specifically to the “7-11” standard—with maximum 7-inch rise and minimum 11-inch tread depth or run. Mr. Daquisto’s criterion (for “7-11” adoption) about evidence, “that benefits of the proposal will exceed the costs,” has been repeatedly provided, including being the lead subject in Pauls’ IRC proposal, in 2003, for the “7-11” rule—submitted sixteen years and five editions of the IRC ago—16 years including over 40 million US stair related injuries and about $900 billion in US stair-related, societal injury costs!

During the 16 years, specifically 2010, Jake Pauls attempted a second set of proposals to update both the IBC and the IRC with respect to home stairway safety, specifically the step dimension rules. That led to a formal appeal to ICC after which the ICC Board refused to deliberate on the matter with the appellant and his counsel. ICC’s refusal to properly address the home stairway safety issue extends right to the top of the organization.

This era of three major attempts to change the ICC codes requirements will end with the current proposal in 2019 after which the effort will be moved—painfully for ICC, the building regulatory field, the building industry, and others—increasingly into the litigation arena as has already gained some momentum in Canada where a significant portion of forensic assignments (of the proponent’s, especially in Ontario) are now in home settings in relation to injuries due to defective stairs.

History within ICC — 2003. The first major public proposal in March 2003, by Jake Pauls, to ICC to change the IRC home stair step dimension requirements to the “7-11” standard was over 18,000 words in length. In addition to epidemiology and etiology aspects of the issue, the proposal dealt extensively with benefit-cost and other issues.

Here is the outline of the entire proposal.

- ICC Public Proposal Form identifying proponent, etc.
- Legislative Text of Proposed Changes (to sections similar to those now addressed).
  - R311.5.3 Stair treads and risers.
    - R311.5.3.1 Riser height.
    - R311.5.3.2 Tread depth.
    - R311.5.3.3 Profile.
- Benefit-Cost Analysis for Improved Stairs in the USA
Some of these topics are still as relevant today as they were in 2003 and a brief update on these is provided below. Nearly an identical proposal was submitted to NFPA in parallel with the ICC proposal during 2003. An NFPA task group was set up to advise on the issue; it strongly recommended adoption. A rule about 7-11 stairs across the board—especially in homes—was adopted. NAHB appealed and lost. Since then NAHB has given up trying to get the NFPA dwelling unit requirements to revert to what the IRC has. Rather, NAHB turned its efforts to stopping NFPA and others from improving home safety through model code adoption at state and local levels in the USA. ICC appeared to be a willing partner in this effort. Ethics apparently took a back seat as ICC continued to give NAHB a guaranteed one-third of the relevant IRC committee’s 12 positions and thus needed only two votes to stop any proposal it did not like. Proponents require 7 votes. The math is clear, as is the need for legal intervention where evidence is treated in much higher regard and nobody with a pre-determined position is allowed to serve as a trier of fact, such as a judge or jury member.

**NAHB’s Political Opposition Spanning Over Two Decades.** The 2003 proposal was not accepted by ICC, largely for what will be termed “political considerations” namely that ICC was not prepared to go against NAHB’s bullying (and other forms of power-based influence) against ICC and building officials generally. Indeed, the political power of the NAHB continues, with ICC’s apparent and effective blessing, two decades after NAHB adopted, in 1996, a policy that stated:

“NOW THEREFORE BE IT RESOLVED that the National Association of Home Builders recommends that all state and local governments who adopt the National Building Code (BOCA) and the Council of American Building Officials (CABO) model building codes, postpone the adoption of any new stair geometry,

BE IT FURTHER RESOLVED that the National Association of Home Builders recommends that all state and local governments who automatically adopt BOCA and CABO model building codes, amend the 1996 and 1995 editions respectively to continue the use of the 1993 BOCA and CABO model codes as they relate to stair geometry provisions,

BE IT FURTHER RESOLVED that the National Association of Home Builders urges all state and local affiliated Home Builders’ Associations to contact state and local code authorities and persuade them to postpone the adoption of the new CABO and BOCA stair geometry standard, and

BE IT FURTHER RESOLVED that the National Association of Home Builders continue to vigorously pursue the adoption of a stair geometry standard consistent with the 1993 BOCA Code.”
The 1993 *BOCA National Building Code* still permitted stairs in dwelling units to have a maximum riser height of 8.25 inches (210 mm) and a minimum tread depth of 9 inches (229 mm); this contrasted with the same Code’s requirements for the “7-11”-based standard for other buildings and occupancies.

**Role of Stair Step Dimensions.** This topic is the most researched aspect of stairway safety and it has a history dating back centuries, indeed, a few millennia (as set out in detail in the proponents 2003 proposal to ICC. This history was described in detail in the proponents proposal in 2003 and will not be repeated here (although, if necessary, it will be part of a comment submitted during 2019 for consideration at the Public Comment Hearing this autumn). Staff can provide the appropriate code change committee with that 2003 proposal if there is a demand from committee members. (It can also be provided to ICC by the proponent if necessary as a PDF file.)

**UK Research Findings.** Since the turn of the century, about two decades ago, there was extensive stairway safety research in the UK at the Building Research Establishment (BRE), a UK version of US NIST or NRC Canada’s former Division of Building Research (up to about 1982). It was briefly noted in the proponent’s 2003 and 2010 proposals on the step dimension issue in the IRC. The charts below are based on many charts and other results produced for the BRE’s sponsor the national agency in the UK responsible for its building regulations. BRE’s research included (1) laboratory studies of ten different stair step run (going or tread depth) dimensions and several different rise dimensions and (2) a mail-back survey of home owners home stair dimensions combined with a survey of falls on their stairs in the preceding two years.

Figure 2 shows one of many results based on both objective measures and test subjects’ responses to a multi-item questionnaire used for each combination of experimental stair rise and run.

![Figure 2. Results of BRE Laboratory Testing of Combinations of Step Rise](image)
Figure 2 is the chart for the most valuable question or assertion for which the study team wanted to know extent of agreement by individual subjects using a scale for which the lower score is associated with a more-preferred step geometry combination. The results, shown in Figure 2, are for the statement, “I felt safe walking down the stair.” There is a streaming video of a discussion between the proponent and one of the two co-investigators, Mike Roys, posted at www.bldguse.com. The discussion, in 2017, focused on the relative importance of the two variables—rise and run—influencing the actual and perceived safety of a stair. While step run (tread depth in the IRC) is very important, there is also some notable effect of the rise. Further research, with larger samples of test subject are needed to pin this down (i.e., statistical significance which was established for the run).

The results of the laboratory studies and the field survey were very similar to what is presented in Figure 3. It shows—for run dimension only—the combined results of the BRE mail-back survey and the laboratory testing; this shows the close correspondence of both subjective and objective measures of the increasing danger of falls when the run dimension is smaller. The vertical scale of the graph in Figure 3 was the basis for estimates, below, on relative risk of falls sufficient to warrant a visit to a hospital Emergency Department in the US.

![Figure 3. Combined Results of BRE Laboratory Testing of Combinations of Step Rise plus Run/Going and the Results of a Mail-back Survey about Home Stair Dimensions](chart.jpg)

The proponent, working with original reports of the UK studies as well as numerous meetings with the UK researchers, at BRE and elsewhere, prepared a table which is partly reproduced below, as Table 3, based on a 2013 publication, that described how step run or tread depth (“going” in UK terminology) affected the risk of an injurious fall sufficiently serious to warrant a visit to a hospital Emergency Department. The range of run (tread depth) dimensions in the table ranged from 190 mm (7.5 inches) to 280 mm (11 inches).
(These results and the full table partly reproduced as Table 3 are found in: Pauls, J. and Barkow, B., 2013. Combining risks from two leading factors in stair-related falls. Proceedings of the International Conference on Fall Prevention and Protection, Tokyo, pp. 87-92, Table 2.)

Table 3. Small Portion of Published Table: Estimated relative annual risks per 100,000 population, of US hospital emergency department visits for home stair-related falls with various nominal run (going) dimensions and with various occurrences of Top of Flight Flaw (TOFF) non-uniformity

Injury Consequences of Inferior Stairs Resulting from NAHB’s Policy and ICC’s Refusal to Improve Home Stair Step Dimensions. What these and many other research findings mean today is that, across much of the USA, there is mix of inferior—indeed dangerously inferior—stairs in homes in their second decade (or more) of a several-decade life. Such homes with stair step tread depths or runs of only 9 inches (even an inch or more smaller effectively, with carpet coverings) are injuring home occupants at rates exceeding those achievable with “7-11” step dimensions by a factor of as much as six to eight. In standard epidemiological terms such NAHB-demanded, home stairs are associated with—per 100,000 population—at least 110 stair-related injuries—annually—leading to hospital emergency room (ER) treatment compared with 20 stair-related injuries for stairs meeting the “7-11” standard. (This relationship and the role of dimensions both nominal and with nonuniformities are discussed in detail in the Pauls-Barkow paper, from 2013, cited above in relation to Table 3.)

Injury Costs. As seen in Table 2 (near the front of this substantiation), for the entire US, in 2018, the ER-treated injury toll alone for such NAHB-demanded stairs is estimated to be on the order of 600,000 injuries. Adding other treatment consequences, i.e., doctors offices and clinics along with hospital admissions brings the annual injury toll into the millions in the US with a societal cost on the order of 100 billion dollars or approaching $1,000 per average US household annually. Note that, societal injury costs for such injuries are composed of three components: medical care, work loss and other direct economic losses, plus pain and suffering (quality of life generally) which are, roughly, in the ratio: one : two : seven, respectively. In other words, medical care cost is the smallest of three components responsible for only about 11 percent of total, societal costs. See figure 4.
Benefits of Normal Stairway Use. Moreover, during a year period, there are on the order of one-trillion stair flight uses in the USA, everyone of which has a value to the stair users. Such normal uses have a significant value that must be taken into account in any benefit-cost analysis. This will increasingly be the case as stairs become safer to use—due to design improvements—and thus such uses can be confidently recommended as a good source of exercise our increasingly sedentary populations need for better fitness. Currently, this proponent cannot endorse use of typical US (or Canadian) home stairs for exercise purposes. Exposure to predictable and preventable dangers has to be minimized and this means that a valuable, readily available place to exercise has less value over its lifetime, simply because its design and construction have been dictated largely by two organizations in the USA: NAHB and SMA, using a flawed code-development process maintained (in an otherwise laudable process for example for its openness and use of communication media) by the ICC.

Concluding Remarks

There are two tactics currently being utilized to change the IRC requirements, one uses ‘micro-surgery’ to change the smallest amount of text in IRC Section on Stairways, focused only on the step dimension issue in relation to specifying minimum tread depth (run) and maximum rise. This would change minimum tread depth from 10 inches to 11 inches and would change maximum rise from 7.75 inches to 7 inches. The other tactic takes a more-comprehensive approach, substituting almost all IRC’s requirements for stairways through a mandatory reference to NFPA 101’s requirements on home stairways, specifically for one- and two-family dwellings—the same scope as the IRC has.

In the proponent’s professional opinion, the first tactic addresses a problem largely created and maintained by the NAHB; the other adds issues for which the SMA is largely responsible due to its largely poorly justified tinkering with a wider range of stairway design issues which owe more to tradition than to technology. SMA’s approach has been marked by the attempt to keep building what has been built in the past, without adequate scientific and technical justification. It appears that SMA has faired very poorly in
attempting to do this in the NFPA process where scientific and technical justification carries more weight.

In the proponent’s professional opinion, both the NAHB and SMA bear much responsibility for the sorry state of home stairway safety in facilities built to the IRC. Ultimately it is ICC that has failed, and—unless drastic actions are taken—will continue to fail us with huge injury ramifications that will last for many decades. This raises questions about the Preface to the IRC which states: (ICC) “provides an international forum for discussion and deliberation about building design, construction methods, safety, performance requirements, technological advances and innovative products.” If this were completely true, why do the requirements of the IRC differ so significantly from those adopted by NFPA?

With the “7-11” being, now, a long-established standard for stairway safety—including in the International Building Code for all settings except one- and two-family dwellings, why is the “7-11” not applied to the setting where it is most needed and where it would produce the largest benefit for the cost of implementation—*in homes*?

**Bibliography:** All citations to the published literature are embedded in the Reason Statement

**Cost Impact:** The code change proposal will increase the cost of construction

While cost of construction will increase, that increase (as shown also in the first proposal on this same topic in a 2003 proposal on stairways in the IRC) pales in comparison to the benefits of the “7-11” step geometry for dwelling unit stairs. (From the Reason Statement comes the following updated detail on cost impact.

"If we assume, as an approximation, there were about 120 million US households in 2012 (the midpoint in the periods discussed above) and further assume an average of one flight of stairs for each household (with some homes having several flights of stairs and many having none), the average cost of home stairway-related injuries is roughly $700 per stair flight (or household) *per year*. This average injury cost greatly exceeds the annual cost (e.g., over a 50-year service life) of a stair flight in a home. As currently allowed by the IRC and built into new homes, stairways with such high annual injury costs are an extremely poor investment in terms of costs to society, families and individuals."

Moreover, for all the other changes proposed for Section 311.7, there is actually a reduction of cost for handrails for example as the more functional handrails are also less costly than the ones typically provided for new home stairways. Changes such as lighting of stairways also have a minor impact on costs as, with modern lighting control systems and energy-saving sources, lighting with increased illumination levels that operates as needed, automatically, means this is not costly as in the past.

**Staff Analysis:** The referenced standard, NFPA 101-18, is currently referenced in other 2018 I-codes.

Proposal # 5467
2018 International Residential Code

Revise as follows:

SECTION R310
EMERGENCY ESCAPE AND RESCUE OPENINGS MEANS OF EGRESS

**R310.1 Means of egress.** Dwellings shall be provided with a means of egress in accordance with this section. The means of egress shall provide a continuous and unobstructed path of vertical and horizontal egress travel from all portions of the dwelling to the required egress door without requiring travel through a garage. The required means of egress door shall open directly into a public way or to a yard or court that opens to a public way.

**R310.2 Egress door.** Not less than one egress door shall be provided for each dwelling unit. The egress door shall be side-hinged, and shall provide a clear width of not less than 32 inches (813 mm) where measured between the face of the door and the stop, with the door open 90 degrees (1.57 rad). The clear height of the door opening shall be not less than 78 inches (1981 mm) in height measured from the top of the threshold to the bottom of the stop. Other doors shall not be required to comply with these minimum dimensions. Egress doors shall be readily openable from inside the dwelling without the use of a key or special knowledge or effort.

**R310.3 Floors and landings at exterior doors.** There shall be a landing or floor on each side of each exterior door. The width of each landing shall be not less than the door served. Landings shall have a dimension of not less than 36 inches (914 mm) measured in the direction of travel. The slope at exterior landings shall not exceed $\frac{1}{12}$ unit vertical in 12 units horizontal (2 percent).

**Exception:** Exterior balconies less than 60 square feet (5.6 m²) and only accessed from a door are permitted to have a landing that is less than 36 inches (914 mm) measured in the direction of travel.

**R310.3.1 Floor elevations at the required egress doors.** Landings or finished floors at the required egress door shall be not more than $1\frac{1}{2}$ inches (38 mm) lower than the top of the threshold.

**Exception:** The landing or floor on the exterior side shall be not more than $7\frac{3}{4}$ inches (196 mm) below the top of the threshold provided that the door does not swing over the landing or floor.

Where exterior landings or floors serving the required egress door are not at grade, they shall be provided with access to grade by means of a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

**R310.3.2 Floor elevations at other exterior doors.** Doors other than the required egress door shall be provided with landings or floors not more than $7\frac{3}{4}$ inches (196 mm) below the top of the threshold.
Exception: A top landing is not required where a stairway of not more than two risers is located on the exterior side of the door, provided that the door does not swing over the stairway.

R311.3.3 R310.3.3 Storm and screen doors. Storm and screen doors shall be permitted to swing over exterior stairs and landings.

R311.4 R310.4 Vertical egress. Egress from habitable levels including habitable attics and basements that are not provided with an egress door in accordance with Section R311.2 shall be by a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

R311.6 R310.5 Hallways. The width of a hallway shall be not less than 3 feet (914 mm).

R310.1.1 R310.6 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exceptions:

1. Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²).
2. Where the dwelling or townhouse is equipped with an automatic sprinkler system installed in accordance with Section P2904, sleeping rooms in basements shall not be required to have emergency escape and rescue openings provided that the basement has one of the following:
   2.1. One means of egress complying with Section R311-Sections R310.2 through R310.6 and one emergency escape and rescue opening.
   2.2. Two means of egress complying with Section R311-Sections R310.2 through R310.6.

R310.1.1 R310.6.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge. Window opening control devices on windows serving as a required emergency escape and rescue opening shall comply with ASTM F2090.

R310.2 R310.7 Emergency escape and rescue openings. Emergency escape and rescue openings shall have minimum dimensions as specified in this section.

R310.2.1 R310.7.1 Minimum opening area. Emergency and escape rescue openings shall have a net clear opening of not less than 5.7 square feet (0.530 m²). The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. The net clear height of the opening shall be not less than 24 inches (610 mm) and the net clear width shall be not less than 20 inches (508 mm).

Exception: Grade floor openings or below-grade openings shall have a net clear opening area of not less than 5 square feet (0.465 m²).

R310.2.2 R310.7.2 Window sill height. Where a window is provided as the emergency escape and rescue opening, it shall have a sill height of not more than 44 inches (1118 mm) above the floor; where the sill height is below grade, it shall be provided with a window well in accordance with Section R319.2.3-R310.7.3.

R310.2.3 R310.7.3 Window wells. The horizontal area of the window well shall be not less than 9 square feet.
(0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened.

**Exception:** The ladder or steps required by Section R310.2.3.1-R310.7.3.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the window well.

R310.2.3.1 Ladder and steps. Window wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the window in the fully open position. Ladders or steps required by this section shall not be required to comply with Section R311.7. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the window well.

R310.7.3.2 Drainage. Window wells shall be designed for proper drainage by connecting to the building’s foundation drainage system required by Section R405.1 or by an approved alternative method.

**Exception:** A drainage system for window wells is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

R310.2.4 Emergency escape and rescue openings under decks and porches. Emergency escape and rescue openings installed under decks and porches shall be fully openable and provide a path not less than 36 inches (914 mm) in height to a yard or court.

R310.2.5 Replacement windows. Replacement windows installed in buildings meeting the scope of this code shall be exempt from the maximum sill height requirements of Section R310.2.2-R310.7.2 and the requirements of Section R310.2.1-R310.7.1, provided that the replacement window meets the following conditions:

1. The replacement window is the manufacturer’s largest standard size window that will fit within the existing frame or existing rough opening. The replacement window is of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

2. The replacement window is not part of a change of occupancy.

R310.8 Emergency escape and rescue doors. Where a door is provided as the required emergency escape and rescue opening, it shall be a side-hinged door or a slider. Where the opening is below the adjacent grade, it shall be provided with an area well.

R310.8.1 Minimum door opening size. The minimum net clear height opening for any door that serves as an emergency and escape rescue opening shall be in accordance with Section R310.2.1-R310.7.1.

R310.8.2 Area wells. Area wells shall have a width of not less than 36 inches (914 mm). The area well shall be sized to allow the emergency escape and rescue door to be fully opened.

R310.8.2.1 Ladder and steps. Area wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the door in the fully open position. Ladders or steps required by this section shall not be required to comply with Section R311.7. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the exterior stairwell.

R310.8.2.2 Drainage. Area wells shall be designed for proper drainage by connecting to the building’s foundation drainage system required by Section R405.1 or by an approved alternative method.
Exception: A drainage system for area wells is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

R310.4 Bars, grilles, covers and screens. Where bars, grilles, covers, screens or similar devices are placed over emergency escape and rescue openings, area wells, or window wells, the minimum net clear opening size shall comply with Sections R310.2.1 through R310.7.3, and such devices shall be releasable or removable from the inside without the use of a key, tool, special knowledge or force greater than that required for the normal operation of the escape and rescue opening.

R310.5s Dwelling additions. Where dwelling additions contain sleeping rooms, an emergency escape and rescue opening shall be provided in each new sleeping room. Where dwelling additions have basements, an emergency escape and rescue opening shall be provided in the new basement.

Exceptions:

1. An emergency escape and rescue opening is not required in a new basement that contains a sleeping room with an emergency escape and rescue opening.
2. An emergency escape and rescue opening is not required in a new basement where there is an emergency escape and rescue opening in an existing basement that is accessed from the new basement.

R310.6s Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing basements undergo alterations or repairs.

Exception: New sleeping rooms created in an existing basement shall be provided with emergency escape and rescue openings in accordance with Section R310.1.

SECTION R311
MEANS OF EGRESS STAIRWAYS AND RAMPS

Add new text as follows:

R311.1 Stairways. Stairways shall comply with Sections R311.1.1 through R311.12.2

Revise as follows:

R311.7.1 Width. Stairways shall be not less than 36 inches (914 mm) in clear width at all points above the permitted handrail height and below the required headroom height. The clear width of stairways at and below the handrail height, including treads and landings, shall be not less than 31 1/2 inches (787 mm) where a handrail is installed on one side and 27 inches (698 mm) where handrails are installed on both sides.

Exception: The width of spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.2 Headroom. The headroom in stairways shall be not less than 6 feet 8 inches (2032 mm) measured vertically from the sloped line adjoining the tread nosing or from the floor surface of the landing or platform on that portion of the stairway.

Exceptions:

1. Where the nosings of treads at the side of a flight extend under the edge of a floor opening through which the stair passes, the floor opening shall not project horizontally into the
required headroom more than 4\(\frac{3}{4}\) inches (121 mm).
2. The headroom for spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.3 R311.1.3 Vertical rise. A flight of stairs shall not have a vertical rise larger than 151 inches (3835 mm) between floor levels or landings.

R311.7.4 R311.1.4 Walkline. The walkline across winder treads and landings shall be concentric to the turn and parallel to the direction of travel entering and exiting the turn. The walkline shall be located 12 inches (305 mm) from the inside of the turn. The 12-inch (305 mm) dimension shall be measured from the widest point of the clear stair width at the walking surface. Where winders are adjacent within a flight, the point of the widest clear stair width of the adjacent winders shall be used.

R311.7.5 R311.1.5 Stair treads and risers. Stair treads and risers shall meet the requirements of this section. For the purposes of this section, dimensions and dimensioned surfaces shall be exclusive of carpets, rugs or runners.

R311.7.5.1 R311.1.5.1 Risers. The riser height shall be not more than 7\(\frac{3}{4}\) inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than 3\(\frac{1}{8}\) inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. At open risers, openings located more than 30 inches (762 mm), as measured vertically, to the floor or grade below shall not permit the passage of a 4-inch-diameter (102 mm) sphere.

Exceptions:

1. The opening between adjacent treads is not limited on spiral stairways.
2. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.5.2 R311.1.5.2 Treads. The tread depth shall be not less than 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread’s leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than 3\(\frac{1}{8}\) inch (9.5 mm).

R311.7.5.2.1 R311.1.5.2.1 Winder treads. Winder treads shall have a tread depth of not less than 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a tread depth of not less than 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3\(\frac{1}{8}\) inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and shall not be required to be within 3\(\frac{1}{8}\) inch (9.5 mm) of the rectangular tread depth.

Exception: The tread depth at spiral stairways shall be in accordance with Section R311.7.10.1.

R311.7.5.3 R311.1.5.3 Nosings. Nosings at treads, landings and floors of stairways shall have a radius of curvature at the nosing not greater than 9\(\frac{1}{16}\) inch (14 mm) or a bevel not greater than 1\(\frac{1}{2}\) inch (12.7 mm). A nosing projection not less than 3\(\frac{3}{4}\) inch (19 mm) and not more than 1\(\frac{1}{4}\) inches (32 mm) shall be provided on stairways. The greatest nosing projection shall not exceed the smallest nosing projection by more than 3\(\frac{1}{8}\) inch (9.5 mm) within a stairway.

Exception: A nosing projection is not required where the tread depth is not less than 11 inches (279 mm).
R311.7.5.4 Exterior plastic composite stair treads. Plastic composite exterior stair treads shall comply with the provisions of this section and Section R507.2.2.

R311.7.6 Landings for stairways. There shall be a floor or landing at the top and bottom of each stairway. The width perpendicular to the direction of travel shall be not less than the width of the flight served. For landings of shapes other than square or rectangular, the depth at the walk line and the total area shall be not less than that of a quarter circle with a radius equal to the required landing width. Where the stairway has a straight run, the depth in the direction of travel shall be not less than 36 inches (914 mm).

Exception: A floor or landing is not required at the top of an interior flight of stairs, including stairs in an enclosed garage, provided that a door does not swing over the stairs.

R311.7.7 Stairway walking surface. The walking surface of treads and landings of stairways shall be sloped not steeper than one unit vertical in 48 inches horizontal (2-percent slope).

R311.7.8 Handrails. Handrails shall be provided on not less than one side of each flight of stairs with four or more risers.

R311.7.8.1 Height. Handrail height, measured vertically from the sloped plane adjoining the tread nosing, or finish surface of ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

Exceptions:

1. The use of a volute, turnout or starting easing shall be allowed over the lowest tread.
2. Where handrail fittings or bendings are used to provide continuous transition between flights, transitions at winder treads, the transition from handrail to guard, or used at the start of a flight, the handrail height at the fittings or bendings shall be permitted to exceed 38 inches (956 mm).

R311.7.8.2 Handrail projection. Handrails shall not project more than $4\frac{1}{2}$ inches (114 mm) on either side of the stairway.

Exception: Where nosings of landings, floors or passing flights project into the stairway reducing the clearance at passing handrails, handrails shall project not more than $6\frac{1}{2}$ inches (165 mm) into the stairway, provided that the stair width and handrail clearance are not reduced to less than that required.

R311.7.8.3 Handrail clearance. Handrails adjacent to a wall shall have a space of not less than $1\frac{1}{2}$ inches (38 mm) between the wall and the handrails.

R311.7.8.4 Continuity. Handrails shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals.

Exceptions:

1. Handrail continuity shall be permitted to be interrupted by a newel post at a turn in a flight with winders, at a landing, or over the lowest tread.
2. A volute, turnout or starting easing shall be allowed to terminate over the lowest tread.

R311.7.8.5 Grip size. Required handrails shall be of one of the following types or provide equivalent graspability.
1. Type I. Handrails with a circular cross section shall have an outside diameter of not less than 1 1/4 inches (32 mm) and not greater than 2 inches (51 mm). If the handrail is not circular, it shall have a perimeter of not less than 4 inches (102 mm) and not greater than 6 1/4 inches (160 mm) and a cross section of not more than 2 1/4 inches (57 mm). Edges shall have a radius of not less than 0.01 inch (0.25 mm).

2. Type II. Handrails with a perimeter greater than 6 1/4 inches (160 mm) shall have a graspable finger recess area on both sides of the profile. The finger recess shall begin within 3/4 inch (19 mm) measured vertically from the tallest portion of the profile and have a depth of not less than 5/16 inch (8 mm) within 7/8 inch (22 mm) below the widest portion of the profile. This required depth shall continue for not less than 3/8 inch (10 mm) to a level that is not less than 1 3/4 inches (45 mm) below the tallest portion of the profile. The width of the handrail above the recess shall be not less than 1 1/4 inches (32 mm) and not more than 2 3/4 inches (70 mm). Edges shall have a radius of not less than 0.01 inch (0.25 mm).

**R311.7.8.6 Exterior plastic composite handrails.** Plastic composite exterior handrails shall comply with the requirements of Section R507.2.2.

**R311.7.9 Illumination.** Stairways shall be provided with illumination in accordance with Sections R303.7 and R303.8.

**R311.7.10 Special stairways.** Spiral stairways and bulkhead enclosure stairways shall comply with the requirements of Section R311.7 except as specified in Sections R311.7.10.1-R311.1.10.1 and R311.7.10.2-R311.1.10.2.

**R311.7.10.1 Spiral stairways.** The clear width at and below the handrails at spiral stairways shall be not less than 26 inches (660 mm) and the walkline radius shall be not greater than 24 1/2 inches (622 mm). Each tread shall have a depth of not less than 6 3/4 inches (171 mm) at the walkline. Treads shall be identical, and the rise shall be not more than 9 1/2 inches (241 mm). Headroom shall be not less than 6 feet 6 inches (1982 mm).

**R311.7.10.2 Bulkhead enclosure stairways.** Stairways serving bulkhead enclosures, not part of the required building egress, providing access from the outside grade level to the basement shall be exempt from the requirements of Sections R311.3-R310.3 and R311.7-R311.1 where the height from the basement finished floor level to grade adjacent to the stairway is not more than 8 feet (2438 mm) and the grade level opening to the stairway is covered by a bulkhead enclosure with hinged doors or other approved means.

**R311.7.11 Alternating tread devices.** Alternating tread devices shall not be used as an element of a means of egress. Alternating tread devices shall be permitted provided that a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches (508 mm).

**Exception:** Alternating tread devices are allowed to be used as an element of a means of egress for lofts, mezzanines and similar areas of 200 gross square feet (18.6 m²) or less where such devices do not provide exclusive access to a kitchen or bathroom.

**R311.7.11.1 Treads of alternating tread devices.** Alternating tread devices shall have a tread depth of not less than 5 inches (127 mm), a projected tread depth of not less than 8 1/2 inches (216 mm), a tread width of not less than 7 inches (178 mm) and a riser height of not more than 9 1/2 inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial tread of the device shall begin at the same elevation as the platform, landing or floor surface.
**R311.7.11.2** Handrails of alternating tread devices. Handrails shall be provided on both sides of alternating tread devices and shall comply with Sections R311.7.8.2, R311.1.8.2, to R311.7.8.6, R311.1.8.6. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

**R311.7.12** Ships ladders. Ships ladders shall not be used as an element of a means of egress. Ships ladders shall be permitted provided that a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches.

**Exception:** Ships ladders are allowed to be used as an element of a means of egress for lofts, mezzanines and similar areas of 200 gross square feet (18.6 m²) or less that do not provide exclusive access to a kitchen or bathroom.

**Add new text as follows:**

**R311.2 Ramps.** Ramps shall comply with Sections R311.2.1 through R311.2.3.3.

**Revise as follows:**

**R311.8.1 Maximum slope.** Ramps serving the egress door required by Section R311.2 shall have a slope of not more than 1 unit vertical in 12 units horizontal (8.3-percent slope). Other ramps shall have a maximum slope of 1 unit vertical in 8 units horizontal (12.5 percent).

**Exception:** Where it is technically infeasible to comply because of site constraints, ramps shall have a slope of not more than 1 unit vertical in 8 units horizontal (12.5 percent).

**R311.8.2 Landings required.** There shall be a floor or landing at the top and bottom of each ramp, where doors open onto ramps, and where ramps change directions. The width of the landing perpendicular to the ramp slope shall be not less than 36 inches (914 mm).

**R311.8.3 Handrails required.** Handrails shall be provided on not less than one side of ramps exceeding a slope of one unit vertical in 12 units horizontal (8.33-percent slope).

**R311.8.3.1 Height.** Handrail height, measured above the finished surface of the ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

**R311.8.3.2 Grip size.** Handrails on ramps shall comply with Section R311.7.8.5, R311.1.8.5.

**R311.8.3.3 Continuity.** Handrails where required on ramps shall be continuous for the full length of the ramp. Handrail ends shall be returned or shall terminate in newel posts or safety terminals. Handrails adjacent to a wall shall have a space of not less than 11/2 inches (38 mm) between the wall and the handrails.

**Reason:** This proposal reorganizes two sections R310 and R311. The intent is to consolidate the different types of egress (Egress Doors, Emergency Escape Windows and Emergency Escape Doors) under one section, Means of Egress and separate Stairways and Ramps into their own section. The deletion of section “R311.5 Landing, deck, balcony and stair construction and attachment” removes a section that is addressed better and
in more detail in other sections of the code. Separating Stairs and Ramps into their own section clears up the hierarchy and when to apply the codes. Having to look for stair and ramp requirements under means of egress can imply these requirements do not apply to garage or deck stairs as they are not part of the means of egress.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal reorganizes the code.
2018 International Residential Code

Revise as follows:

R312.1.1 Where required. Guards shall be provided for those portions of open-sided walking surfaces, including floors, stairs, ramps and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a guard.

Reason: The first sentence of the IRC, section R312.1.1, is revised by deleting the phrase “walking surfaces, including” and replacing it with the word “floors.” As amended, guards are required along open-sided floors, stairs, ramps, and landings when they are located more than 30 inches vertically to the floor or grade below. This change is necessary because the term “walking surfaces” is too broad and can be misinterpreted to apply to almost any surface on or in a building or a lot. This requirement could be interpreted to mean that guards are required to be installed around window wells, on the top of retaining walls, along driveways and sidewalks, on landings near window wells, at the edge of swimming pools, and even at the edge of flat roofs. It is reasonable to use terms that are currently defined and that will best convey the intent of the requirement.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. Depending on interpretation, this code clarification may even save costs.
2018 International Residential Code

Revised as follows:

R312.1.2 Height. Required Where installed, guards at open-sided walking surfaces, including stairs, porches, balconies or landings, shall be not less than 36 inches (914 mm) in height as measured vertically above the adjacent walking surface or the line connecting the nosings.

Exceptions:

1. Guards on the open sides of stairs shall have a height of not less than 34 inches (864 mm) measured vertically from a line connecting the nosings.

2. Where the top of the guard serves as a handrail on the open sides of stairs, the top of the guard shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm) as measured vertically from a line connecting the nosings.

R312.1.3 Opening limitations. Required Where installed, guards shall not have openings from the walking surface to the required guard height that allow passage of a sphere 4 inches (102 mm) in diameter.

Exceptions:

1. The triangular openings at the open side of stair, formed by the riser, tread and bottom rail of a guard, shall not allow passage of a sphere 6 inches (153 mm) in diameter.

2. Guards on the open side of stairs shall not have openings that allow passage of a sphere 4 3/8 inches (111 mm) in diameter.

Reason: The way the language is currently written, only required guards need to meet the height and opening limitations. Meaning guards on a low (30 inches or less above grade) deck, installed voluntarily as a design choice, are permitted to be lower than 36-inches and with openings which would allow small children to get caught in. Just like many other code provisions, if a component is installed, whether it is required or not, it should meet the safety requirements of the code instead of providing a false sense of security.

Cost Impact: The code change proposal will increase the cost of construction
This change will likely marginally increase the cost of construction for those elevated walking surfaces that are 30 inches or less that voluntarily choose to install guards.
2018 International Residential Code

Revise as follows:

R312.2.1 Window sills. Lowest part of window openings. In dwelling units, where the top-lowest part of the sill opening of an operable window opening is located less than 24 inches (610 mm) above the finished floor and greater than or more than 72 inches (1829 mm) above the finished grade or other walking surface below the exterior of the building, the operable window shall comply with one of the following below, the lowest part of the window opening shall be not less than 36 inches (914 mm) above the finished floor of the room in which the window is located.

Exceptions:

1. Operable window openings—windows that will not allow a 4-inch- diameter (102 mm) sphere to pass through where the openings are in their largest opened position.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.
3. Operable windows with openings that are provided with window opening control devices that comply with Section R312.2.
4. Replacement windows where the lowest part of the opening is not lower than that of the existing window and the maximum width of the opening of the replacement window does not exceed that of the existing window.

Reason: The first sentence of IRC, section R312.2.1, deletes the IRC language “the lowest part of the clear opening of the window” and replaces it with the phrase “the lowest part of the window opening.” The IRC Technical Advisory Group (TAG) determined that “the lowest part of the window opening” meant the same thing as “lowest part of the clear opening.” The proposed text “lowest part of the window opening” is also consistent with the proposed definition for “sill height” in Code Section 202 (definitions), which clarifies the meaning of sill height pertaining to emergency escape and rescue openings. The first sentence also replaces the phrase “24 inch above finished floor” with “36 inches above the floor.” The 24- and 36-inch dimensions are heights that establish a threshold at which the window fall protection requirements are required. The threshold dimension in the current code is set at 24 inches. The IRC sets this dimension at 24 inches, while the IBC sets this dimension at 36 inches. This threshold dimension must be coordinated between the two codes to provide consistent application and enforcement in residential construction. Windows installed having the lowest part of the window opening below this threshold will require window fall protection compliance. The TAG determined that the 36-inch dimension is reasonable because it will provide increased life safety for occupants since raising the threshold dimension from 24 to 36 inches will require more windows to be fall protection compliant. Requiring more windows to have fall protection devices installed will provide increased life safety to more occupants, especially children. Additionally, these more restrictive requirements are consistent with the intent of codes which require compliance with the standards for window fall protection devices established in the Codes. The proposed exception #4 is added to exempt replacement windows from the window fall protection requirements. The TAG determined that requiring window fall protection devices in replacement windows would mandate retroactive code compliance for existing structures. Typically, the code is not retroactive for existing structures, with the exception of smoke alarms and safety glazing. If homeowners of existing homes are required to add safety devices that must comply with ASTM F 2090, they may not be as likely to replace
windows that trigger this requirement. It is not reasonable to require window fall protection safety devices that may discourage homeowners from replacing old windows that are broken or painted shut.

There will be an increase to the overall cost of windows in a comparable residential unit. Double-hung windows are currently dominant in the market in sizes that would be most likely be affected by adding a window fall protection device would cost about $30.00 per window. On casement windows, which currently have a smaller share of the market, adding a window fall protection device would increase the cost by approximately $100.00 per window.

**Cost Impact:** The code change proposal will increase the cost of construction
Yes there will be a cost increase for some windows depending on the locations where they are installed, however, these more restrictive requirements are being incorporated into the proposed code to provide for increased life safety for the occupants, to coordinate the provisions of the IBC and IRC, and to provide a more consistent application and enforcement between the Codes in Residential construction in both the IBC and the IRC.
2018 International Residential Code

Revise as follows:

R312.2.1 Window sills. opening height. In dwelling units, where the top bottom of the sill clear opening of an operable window opening is located less than 24 inches (610 mm) above the finished floor and greater than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, the operable window shall comply with one of the following:

1. Operable window openings will not allow a 4-inch-diameter (102 mm) sphere to pass through where the openings are in their largest opened position.
2. Operable windows are provided with window fall prevention devices that comply with ASTM F2090.
3. Operable windows are provided with window opening control devices that comply with Section R312.2.2.

Reason: This proposal is to change the language on how to measure when you need to protect for child fall protection. Since there is not a definition of sill and typically a window sill is lower than the actual bottom of window opening the language should reflect measuring to the bottom of the actual window opening. This language was changed in the 2015 as a part of a larger change with no apparent reason for this language. I have written a companion change to IRC Section R310.2.2 for egress window heights. This language will now match the revised language that was approved by membership for section IBC 1015.8 as per code change E80-2021

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal is to help clarify the intent of the code
2018 International Residential Code

Revise as follows:

R312.2.1 Window sills. In dwelling units, where the top of the sill of an operable window opening is located less than 24 inches (610 mm) above the finished floor or any other horizontal surface below that is within the framed opening of the window, and greater than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, the operable window shall comply with one of the following:

1. Operable window openings will not allow a 4-inch-diameter (102 mm) sphere to pass through where the openings are in their largest opened position.
2. Operable windows are provided with window fall prevention devices that comply with ASTM F2090.
3. Operable windows are provided with window opening control devices that comply with Section R312.2.2.

Reason: The National SAFE KIDS campaign indicate that 4,700 children annually in the United States require treatment following a fall from a window. About 18 of these children die from such falls. ASTM F2090 is referenced as a required step in the prevention side with fall protection devices and their installation requirements, but now we need to go a step further. The U.S. Consumer Product Safety Commission studies reported that the majority of child falls occurred from the first and second floors. When the requirement for fall protection came in with the 72 inch above grade or exterior surface below requirement, and the 24 inch interior height above finish floor, there was one thing missing.....Built in Furnishings, such as window seats. We have seen many plans submitted for permits with window seats that are 18 inches maximum above the finished floor. This is a height that a child can climb up onto, and now we have a walking surface with the window sill height only inches above. It is understood that anyone can move a piece of furniture such as a hope chest or table under the window sill, but we are not here to monitor what people will do after the fact, we are here to educate, along with establishing codes that help protect and save lives. We are here to make places where we live, work, educate, assemble, etc. safer. Having this requirement in the body of the code is a step closer to bringing that 4,700 statistic down.

This entire issue hit close to home when an employees child fell from the second floor of a dwelling. My Plumbing Inspectors child had pushed the screen of an opened window toppling out the window and landing in an empty hot tub that was up against the house. This was due to a bed being pushed up against the window. This child was hospitalized for approximately a month with severe head and liver injuries. If the hot tub hadn’t been there, a concrete patio is where he would have landed. The outcome could have been much more grim than it was. Children are curious and they do not recognize danger. They like to climb and explore, and they are top heavy with their center of gravity up near their chest. By inserting this text into section R312.2.1, we are establishing fall protection when window seats or furnishings are constructed below the window. If a window sill happens to be 27 inches above the finish floor and a window seat is constructed at 18 inches above the finish floor, we now have a walking surface with the window sill 9 inches above (see Exhibit A), well below their center of gravity. This is a prime opportunity for a child to get in trouble. By inserting this text in to R312.2.1 for any horizontal surface constructed beneath the window, we are reducing the opportunity for a child to fall. To keep the a child's center of gravity below the windows edge, we have to require the 24 inch requirement from ANY horizontal surface that they can climb upon. I personally know toddlers who can climb up on a 24 inch window seat with no effort at all.
It is very important that we educate the occupants of these dwellings on moving furniture in front of a window. But in addition to that, we can reduce the statistics by not permitting built-in raised walking surfaces within 24 inches of the bottom of the window. Every study from the National Safety Council to Consumer Reports lists one of the main problems is furniture in front of a window. A report from WebMD and the American Academy of Pediatrics in 2011 (attached) mentions several times that a major preventer is keeping furniture away from windows. If this is the case, why would we allow these homes to be built with permanent furniture in front of a window without protection? If permanent furniture is to be built in front of a window, then the windows bottom edge needs to be 24 inches or greater above the permanent furnishings, or fall under the requirements of R312.2.1. We have a hard time enforcing R312.2.1 when window seats are constructed because code states only above the finish floor. Some will say that beings how a toddler can climb up on the seat and walk on it that is a walking surface. This doesn't work because there is no definition for a walking surface in the code. This is easily remedied by adding the text to R312.2.1.

Falls from Windows Injure Nearly 100,000 U.S. Children in 19-Year Period
10/22/2011
During a 19-year period, an estimated 98,145 children were treated in U.S. emergency departments for injuries sustained in falls from windows.

The study, "Pediatric Injuries Attributable to Falls from Windows in the United States in 1990-2008" is the first study to use a nationally representative sample to identify risk factors and trends for pediatric window fall-related injuries treated in US hospital emergency departments. The authors found that windows falls occur more frequently during spring and summer months. The rate of injury is higher for children younger than 5 years of age, and those children were more likely to sustain serious injuries. In addition to young age, a fall height of three stories or higher and a hard landing surface (such as concrete) increased the risk for serious injuries.

Window fall prevention measures for young children should include the use of window guards or window looks and moving furniture away from windows to decrease a young child's access. Another way to reduce injuries is to consider the surface below windows. Simply planting bushes or plant beds under windows can soften the landing surface, reducing impact and the resulting injuries.

5,000 kids a year hurt in falls from windows

The number of children treated in U.S. emergency departments for falls from windows approached 100,000 between 1990 and 2008, says a study in the journal Pediatrics. The research shows that the number of injuries declined during the first decade of the study period, but has since plateaued.

"We still are seeing over 5,000 children a year treated in hospital emergency departments across the country for injuries related to window falls," said Dr. Gary A. Smith, study author and director of the Center for Injury Research and Policy at Nationwide Children's Hospital in Columbus, Ohio. "That's 14 children a day. This continues to be a very common, important problem."

Researchers studied data from the National Electronic Injury Surveillance System, maintained by the U.S. Consumer Product Safety Commission. The group monitors injuries involving consumer products, treated in emergency departments nationwide. Researchers divided data from almost 4,000 patients into two groups: 0-4 years and 5-17 years.

Boys were involved in more falls from windows than girls were. In addition, the younger children made up two-thirds of the injuries. The injury rate was highest at age 2.

"These are kids who don't recognize danger - they're curious, they want to explore and when they see an open window, they are going to investigate," Smith said. "Kids at that age tend to be top heavy. Their center of gravity is up near their chest and so as they lean out of the window to see what's going on, they'll topple."

Many of the young children experienced injuries to their head or face, and, often times, these led to hospitalization or death. On the other hand, children in the older group were more likely to have fractures to their arms or legs.

While a few children did fall from a third story or higher, many more fell from a first- or second-story window.

"What we're finding is that most of these aren't these really high-rise buildings," Smith added. "These are just often homes or apartments that aren't high-rise, where children live. This is a problem that extends to small towns and even rural areas across the country."

He reinforces the message that a screen does not offer protection and should give parents no feeling of comfort.

Smith, who is a pediatric emergency medicine physician, offers the following advice for parents.
Parents of children younger than 5:
- Use window guards or locks
- Do not allow any window to be open more than four inches
- Move furniture away from windows so children cannot climb on it

Parents of children older than 5:
- Educate children and teens of the risk of climbing out of a window or jumping from it

The authors also note that the landing surface made a difference. The patients who ended up on a cushioned surface often fared better than those who ended up on a hard surface.

"Our focus should be on preventing the child from falling in the first place, but cushioning the fall can help," Smith noted.

"If a child falls from a window and they land on bushes or a planted flower bed, that often is enough to cushion the fall so that they'll end up with bruises or scrapes instead of a severe injury," he said.

The study points out that great reductions were seen in New York and Boston after programs were implemented there to combat the problem. The programs involved education in the community and among parents. Window guards were also made available. In New York City, window guards became mandatory in apartments where young children lived.

"We know what works," Smith said. "We need to now go out and implement that."

Smith said there were limitations with the set of data, especially with fatality numbers, and therefore these numbers under represent the problem.

Preventing Window Falls

Laela’s Law, the first statewide window fall prevention legislation, references two ASTM standards

by Richard Wilhelm

On June 16, 2006, Laela Shaugobay, then not quite 2 years old, climbed on a piece of furniture pushed on an insect screen and fell from a fourth-floor apartment window in Franklin, Minn.

Laela was critically injured but survived the fall and has since fully recovered. However, statistics compiled by the National SAFE KIDS campaign indicate that Laela is one of approximately 4,700 children annually in the United States who require treatment following a fall from a window. According to these same statistics, about 18 children per year die from such falls.

Laela’s case inspired action, which resulted in the 2007 passage of a Minnesota state law setting standards for stronger child fall prevention screens and other window fall prevention devices. Laela’s Law, as it is now known, took effect in Minnesota on July 1 of this year.

Both standards were developed by Subcommittee F15.38 on Window Fall Prevention, part of ASTM International Committee F15 on Consumer Products.
Kathryn Coen, product safety engineer, product safety and liability prevention group, Anderson Corp., and current chair of Subcommittee F15.38, says that F2006 and F2090 can be used in legislation and in building codes, as well as by individual parents who can purchase devices to comply to the standards for their own homes. “F15.38 wants to educate adults on the importance of window safety, and our standards play an important role in this,” says Coen.

History of Subcommittee F15.38

Subcommittee F15.38 was formed in 1995 following a roundtable meeting and a report issued by the U.S. Consumer Product Safety Commission that found that children age 5 and younger account for a high percentage of window fall fatalities and injuries.

The first standard approved by the subcommittee, F2006, applies strictly to fall prevention devices that protect against potential falls by children age 5 and under through open windows designated for emergency escape or rescue in installations more than 75 ft. (23 m) above ground level in multiple family dwellings. Windows at these heights are beyond the reach of rescue ladders currently in use.

With its second approved standard, F2090, Subcommittee F15.38 covers window fall prevent devices for windows situated up to 75 ft. (23 m) above ground. At this height level, windows have emergency escape release mechanisms, which needed to be taken into account in the standard.

According to its introduction, F2090 addresses window fall prevention devices that protect against potential falls by children age 5 years and under through open windows. The standard covers a variety of currently available window fall prevention devices, including window opening control devices, window fall prevention screens and some types of window guards, all of which use different strategies to prevent children from falling through open windows.

ASTM F2090 covers the general requirements, installation instructions and performance tests for window fall prevention devices, which are defined in the standard as “any device intended to prevent a young child from passing or falling through an open window.” The definition goes on to note that such devices may be an integral part of a window or may be attached to the window or its frame or the area around the window after the window has been installed. F2090 also includes examples of safety information panels to be used within assembly/installation instructions.

Window Fall Prevention Devices

Three types of window fall prevention devices described in the F15.38 standards are:

- Fall prevention window guard — Device designed to fit into or onto a window to prevent a child from passing or falling through an open window. Typically mounted on the interior frame of window and includes side frames fastened to the sides of a window frame and a plurality of
spaced-apart, transverse, tubular, width-adjustable crosspiece elements to form a grid pattern between the side supports to prevent passage of a child.

- Window fall prevention screen — Screen device designed to fit into or onto a window to prevent a child from passing or falling through an open window. Typically mounted on the exterior surface/frame of a sliding style window and on the interior of a cranking style window and includes screening mesh or material and attachment mechanism(s) of sufficient strength to meet the performance requirements of this standard while preventing passage of a child.

- Window opening control device — Device that limits a window sash to be opened with normal operation of the sash such as to prohibit the free passage of a 4-in. (102-mm) diameter rigid sphere at the lowest opening portion of the window opening, with a release mechanism that shall allow the sash to be opened to a large opening area such as that required for emergency escape and rescue, and that automatically resets when a window is fully closed.

According to Coen, the subcommittee is currently in the process of updating F2090 and invites all interested parties to contribute to future revisions. “We are having ongoing virtual meetings to get everyone on the same page regarding potential updates to the standard,” says Coen.

“There is a wide range of subcommittee members, including parents whose children have been in window fall accidents, injury prevention and fire safety experts, building code officials, homebuilders, window manufacturers, makers of fall prevention devices and CPSC representatives,” says Coen, who notes that the subcommittee is particularly interested in having input from fire safety experts at this time.

Coen is hopeful that the use of F15.38 standards in building codes and in legislation such as Laela’s Law, along with continuing education and information dissemination, will help to lower the incidence of window falls in the future.
About 5,000 Kids Fall From Windows Each Year

Simple Prevention Measures Include Installing Locks, Keeping Furniture Away From Windows

By Jennifer Warner

Aug. 22, 2011 -- Falls from windows injure about 5,100 children on average each year in the U.S., and most could be prevented with simple window safety measures.

A new study shows an estimated 98,415 children were treated in hospital emergency rooms from 1990 to 2008 for injuries caused by falls from windows. Injuries ranged from cuts and bruises to fatal head injuries, and young children were most at risk for serious injuries.

Researchers say it's the first study to look at the risk factors and injuries associated with children's falls from windows. The results suggest that many of these injuries could be prevented with simple steps, such as moving furniture away from windows, installing locks, and placing plant beds or bushes under windows.

Window Fall Risks

In the study, researchers analyzed information from a nationwide database of children treated in hospital emergency rooms over a 19-year period from 1990 to 2008.

Continue Reading Below

The results showed that an estimated 98,415 children were treated for injuries caused by a fall from a window during this period, an average of 5,180 per year.

Researchers found the following factors were associated with window falls:

- Boys were more likely than girls to fall out of windows and accounted for 58% of window fall injuries.
- Falls from windows were more common in spring and summer months.
- One-fourth of the window fall-related injuries required hospitalization.
- Children under 5 years were more likely to suffer serious injuries from a window fall and three times more likely to suffer a head injury.

The study also showed that the type of landing surface plays a major role in the severity of head injuries caused by window falls. Children who landed on a hard surface, such as concrete, were twice as likely to suffer head injuries, be hospitalized, or die from their injuries compared with those who landed on cushioned surfaces.

How to Improve Window Safety
Researchers say placing bushes or plant beds underneath windows can create a cushioned landing surface and reduce the impact of falls from windows for children of all ages.

WebMD Health News Reviewed by Laura J. Martin, MD on August 22, 2011

Other steps to increase window safety include reducing access to windows by moving furniture away from windows and installing window guards or locks that prevent the window from opening more than 4 inches.

Although information about whether furniture was placed near the window was not available for 95% of the falls, researchers found 4% of window falls involved children rolling off beds or climbing on furniture before falling out a window.

Similarly, there was little information about whether a screen was in place at the time of the fall. But when this information was available, 83% reported that a screen was in place.

“Findings from other studies demonstrate that screens often are in place (up to 76% of the time) but do not provide adequate protection against window falls involving children,” researcher Vaughn A. Harris, of the Center For Injury Research and Policy, The Research Institute at Nationwide Children’s Hospital, in Columbus, Ohio, and colleagues write in *Pediatrics*. “Parents and other child caregivers should be counseled not to depend on screens to prevent children from falling out windows.”

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There would be minimal to no cost impact on this change.

Proposal # 3973
2018 International Residential Code

Revise as follows:

SECTION R312

GUARDS AND WINDOW FALL PROTECTION

R312.2 Window fall protection. Window fall protection shall be provided in accordance with Sections R312.2.1 and R312.2.2.

R312.2.1 Window sills. In dwelling units, where the top-bottom of the sill-clear opening of an operable window opening is located less than 24 inches (610 mm) above the finished floor and greater than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, the operable window shall comply with one of the following:

1. Operable window openings will not allow a 4-inch-diameter (102 mm) sphere to pass through where the openings are in their largest opened position.
2. Operable windows are provided with window opening control devices or fall prevention devices that comply with ASTM F2090.
3. Operable windows are provided with window opening control devices that comply with Section R312.2.2.

R312.2.2 Window opening control devices. Emergency escape and rescue openings. Window opening control devices shall comply with ASTM F2090. The Where an operable window serves as an emergency escape and rescue opening, the window opening control device or fall prevention devices, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit to less than the area required by Section R310.2.1.

Reason: ASTM F2090, Specification for Window Fall Prevention Devices with Emergency Escape (Egress Release Mechanisms), includes criteria for window fall prevention devices and window opening control devices (see Section R312.2). This standard is specifically written for window openings within 75 feet (22 860 mm) of grade and specifically allows for windows to be used for emergency escape and rescue. This standard was updated in 2008 to address window opening control devices. This control device can be released from the inside to allow the window to be fully opened in order to comply with the emergency escape provisions in IRC. Section 312.2.2.1 - The change to the first sentence is to clarify where the measurement for the bottom of the window should be taken. Exception 2 and 3 are combined since ASTM F2090 includes information on both opening control devices and fall prevention devices.

Section 312.2.2 - The revision does not require opening control devices or fall prevention devices. This section would just allow for them to be on windows that were also serving as emergency escape and rescue openings. This is coordinated with the proposals for emergency escape and rescue openings.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included
members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is a clarification with no technical changes.

Proposal # 4145

RB123-19
312.3 Roof guards. Guards shall be provided where various components that require service are located within 10 feet (3048 mm) of a roof edge or open side of a walking surface and such edge or open side is located more than 30 inches (762 mm) above the floor, roof or grade below. The guards shall extend not less than 30 inches (762 mm) beyond each end of such components. The guard shall be constructed so as to prevent the passage of a sphere 21 inches (533 mm) in diameter.

Guards shall be provided where the roof hatch opening is located within 10 feet (3048 mm) of a roof edge or open side of a walking surface and such edge or open side is located more than 30 inches (762 mm) above the floor, roof or grade below. The guard shall be constructed so as to prevent the passage of a sphere 21 inches (533 mm) in diameter.

Exception: Guards are not required where permanent fall arrest/restraint anchorage connector devices that comply with ANSI/ASSE Z 359.1 are affixed for use during the entire roof covering lifetime. The devices shall be reevaluated for possible replacement when the entire roof covering is replaced. The devices shall be placed not more than 10 feet (3048 mm) on center along hip and ridge lines and placed not less than 10 feet (3048 mm) from the roof edge or open side of the walking surface

Reason: To create parity with the IRC and the IBC, IMC, IFC, and the SRCC requirements for guards. This exception to the requirement for guards is currently in these codes. We are looking to create parity with the requirements and have the same requirement in the IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

No cost impact. The installation of the ANSI/ASSE Z 359.1 devices offset any increase in construction costs.
2018 International Residential Code

Revise as follows:

SECTION R314
SMOKE ALARMS AND HEAT DETECTION

R314.1 General. Smoke alarms, heat detectors, and heat alarms shall comply with NFPA 72 and Section R314.

R314.1.1 Listings. Smoke alarms shall be listed in accordance with UL 217. Heat detectors and heat alarms shall be listed for the intended application. Combination smoke and carbon monoxide alarms shall be listed in accordance with UL 217 and UL 2034.

R314.2 Where required. Smoke alarms, heat detectors, and heat alarms shall be provided in accordance with this section.

R314.2.1 New construction. Smoke alarms shall be provided in dwelling units. A heat detector or heat alarm shall be provided in new attached garages.

R314.2.2 Alterations, repairs and additions. Where alterations, repairs or additions requiring a permit occur, the individual dwelling unit shall be equipped with smoke alarms located as required for new dwellings.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, the addition or replacement of windows or doors, or the addition of a porch or deck.
2. Installation, alteration or repairs of plumbing or mechanical systems.

Add new text as follows:

R314.2.3 New attached garages. A heat detector or heat alarm rated for the ambient outdoor temperatures and humidity shall be installed in new garages that are attached to or located under new and existing dwellings. Heat detectors and heat alarms shall be installed in a central location and in accordance with the manufacturer’s instructions.

Exception: Heat detectors and heat alarms shall not be required in dwellings without commercial power.

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
3. On each additional story of the dwelling, including basements and habitable attics and not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full
4. Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by this section.

R314.3.1 Installation near cooking appliances. Smoke alarms shall not be installed in the following locations unless this would prevent placement of a smoke alarm in a location required by Section R314.3.

1. Ionization smoke alarms shall not be installed less than 20 feet (6096 mm) horizontally from a permanently installed cooking appliance.
2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3048 mm) horizontally from a permanently installed cooking appliance.
3. Photoelectric smoke alarms shall not be installed less than 6 feet (1828 mm) horizontally from a permanently installed cooking appliance.

Revise as follows:

R314.4 Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling unit in accordance with Section R314.3, the alarm devices shall be interconnected in such a manner that the actuation of one alarm will activate all of the alarms in the individual dwelling unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm.

Exception: Smoke alarms and alarms installed to satisfy Section R314.4.1 shall not be required to be interconnected to existing smoke alarms where such existing smoke alarms are not interconnected or where such new smoke alarm or alarm is not capable of being interconnected to the existing smoke alarms.

Add new text as follows:

R314.4.1 Heat detection interconnection. Heat detectors and heat alarms shall be connected to an alarm or a smoke alarm that is installed in the dwelling. Alarms and smoke alarms that are installed for this purpose shall be located in a hallway, room, or other location that will provide occupant notification.

R314.5 Combination alarms. Combination smoke and carbon monoxide alarms shall be permitted to be used in lieu of smoke alarms.

Revise as follows:

R314.6 Power source. Smoke alarms, alarms, and heat detectors shall receive their primary power from the building wiring where such wiring is served from a commercial source and, where primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. Smoke alarms shall be permitted to be battery operated where installed in buildings without commercial power.
2. Smoke alarms installed in accordance with Section R314.2.2 shall be permitted to be battery powered.

R314.7 Fire alarm systems. Fire alarm systems shall be permitted to be used in lieu of smoke alarms and shall comply with Sections R314.7.1 through R314.7.4.
R314.7.1 General. Fire alarm systems shall comply with the provisions of this code and the household fire warning equipment provisions of NFPA 72. Smoke detectors shall be listed in accordance with UL 268.

R314.7.2 Location. Smoke detectors shall be installed in the locations specified in Section R314.3.

R314.7.3 Permanent fixture. Where a household fire alarm system is installed, it shall become a permanent fixture of the occupancy, owned by the homeowner.

R314.7.4 Combination detectors. Combination smoke and carbon monoxide detectors shall be permitted to be installed in fire alarm systems in lieu of smoke detectors, provided that they are listed in accordance with UL 268 and UL 2075.

Reason: An estimated 9,000 residential garage fires are reported to United States fire departments each year and cause an estimated 50 deaths, 400 injuries, and $557 million in property loss (NFPA Research Report: Home Structure Fires, September 2017). Fires that originate in residential garages are normally larger, spread farther, and cause more damage than fires that start in other areas of a home. This is largely due to garages not having any means of smoke or heat detection. By the time a smoke detector in the dwelling detects the fire, or the home owner or a neighbor notices the fire, it is often too late, and the fire has begun to burn through the fire separation between the garage and the dwelling. At this point, the fire rapidly spreads through wall cavities and begins to attack the structural parts of the home. Unfortunately, smoke alarms installed in garages may lead to nuisance alarms due to vehicle exhaust fumes.

Installing a heat detector or heat alarm in these unprotected areas of a home will significantly reduce fire related deaths, injuries, and property loss.

Bibliography:
3. USFA Prevent Home Garage Fires.

**Cost Impact:** The code change proposal will increase the cost of construction

- An interconnected heat detector or heat alarm will increase the cost of construction by about $100, which includes installation.
- If a new garage is attached to an existing dwelling that has only battery powered smoke alarms installed, the heat detector or heat alarm will require the installation of an interconnected alarm or smoke alarm to be installed in the dwelling for the purposes of providing occupant notification. Under this scenario, the total cost will increase to about $200.

Proposal # 4850

RB125-19
RB126-19
IRC®: R314.2 (New), R314.3, R315.3

Proponent: Gregory Wickline, Snohomish county, representing self (gwickline@comcast.net)

2018 International Residential Code
Revise as follows:

R314.2 Where required. Smoke alarms shall be provided in accordance with this section.

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
3. On each additional story of the dwelling, including basements and habitable attics and not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.
4. Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by this section.
5. In attics where fuel-fired appliances are installed.

R315.3 Location. Carbon monoxide alarms in dwelling units shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms. Where a fuel-burning appliance is located within a bedroom or its attached bathroom, a carbon monoxide alarm shall be installed within the bedroom. Where a fuel fired appliance is located in and attic, a carbon monoxide alarm shall be installed within the attic.

Reason: More and more I see furnaces being installed in attics and if it was to catch fire, no one would ever know

Cost Impact: The code change proposal will increase the cost of construction
20 bucks

Proposal # 3549

RB126-19
RB127-19
IRC®: R314.3

Proponent: Timothy Pate, Colorado Chapter Code Change Committee, representing City and County of Broomfield (tpate@broomfield.org)

2018 International Residential Code
Revise as follows:

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
3. On each additional story of the dwelling, including basements and habitable attics and not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.
4. Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by this section.
5. In dwelling units where the ceiling height of a room open to a hallway serving bedrooms exceeds that of the hallway by 24 inches (610 mm) or more smoke alarms shall be installed in the hallway and in the room open to the hallway.

Reason: The proposed added language existing on one of the legacy codes and did not make it into the IRC or the IBC. It is not clear why it did not. In the case of a floor plan that has a taller ceiling immediately outside the hallway that leads to the bedrooms smoke from a fire would move to the upper level of the taller ceiling first and then have to build up to get down to the level of the hallway that leads to the bedrooms and where the required smoke alarm is placed. It makes sense to put a smoke alarm at the taller ceiling so as to signal smoke from a fire quicker in order to notify the occupants of a problem. This would not be a significant cost addition since it would be a small amount or wiring along with one more smoke alarm. It is proven that smoke alarms do save lives. This would be even more important for the many jurisdictions that have amended out the residential fire sprinkler requirements.

Cost Impact: The code change proposal will increase the cost of construction
There will be additional cost for wiring and smoke alarms

Proposal # 4521

RB127-19
RB128-19

IRC®: R314.3 (New), R315.3

Proponent: Lisa Simmons, Dorchester County, representing Dorchester County (lsimmons2@dorchestercountysc.gov)

2018 International Residential Code

Revise as follows:

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
3. On each additional story of the dwelling, including basements and habitable attics and not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.
4. Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by this section.
5. Inside each room located on the second floor of a detached garage or accessory structure where supplied with power.

R315.3 Location. Carbon monoxide alarms in dwelling units shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms. Where a fuel-burning appliance is located within a bedroom or its attached bathroom, a carbon monoxide alarm shall be installed within the bedroom. Carbon monoxide alarms shall be installed inside each room located on the second floor of a detached garage or accessory structure where supplied with power.

Reason: This area could be occupied as habitable space or used for sleeping purposes.

Cost Impact: The code change proposal will increase the cost of construction
The cost impact would be one additional smoke/carbon monoxide alarm combo.

Proposal # 419
R314.3.1 Installation near cooking appliances. Smoke alarms shall not be installed in the following locations unless this would prevent placement of a smoke alarm in a location required by Section R314.3.

1. Ionization smoke alarms shall not be installed less than 20 feet (6096 mm) horizontally from a permanently installed cooking appliance.
2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3048 mm) horizontally from a permanently installed cooking appliance.
3. Photoelectric smoke alarms shall not be installed less than 6 feet (1828 mm) horizontally from a permanently installed cooking appliance.
4. Smoke alarms listed and marked “helps reduce cooking nuisance alarms” shall not be installed less than 6 feet (1828 mm) horizontally from a permanently installed cooking appliance.

Reason: This proposal recognizes that smoke alarms listed to the new edition of UL 217 (with an effective date of May 29, 2020) are required to pass tests designed to reduce nuisance alarms caused by residential cooking. The proposal provides an additional option for the types of smoke alarms that can be used near cooking appliances, without changing additional options.

The wording is based on the following 2019 NFPA 72 language:

29.11.3.4 (6) Effective January 1, 2022, smoke alarms and smoke detectors installed between 6 ft (1.8 m) and 20 ft (6.1 m) along a horizontal flow path from a stationary or fixed cooking appliance shall be listed for resistance to common nuisance sources from cooking.

There is no need to reference the 2022 effective date in NFPA 72 because if smoke alarms are listed to the new requirements prior to that date they should be allowed to be used as an option to the other technologies provided in Items 1 to 3.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will increase the cost of construction. The increased cost will be for providing carbon monoxide detection when classrooms in Group E occupancies are covered by these code sections.

Proposal # 4309
2018 International Residential Code

Revise as follows:

R315.2.2 Alterations, repairs and additions. Where alterations, repairs or additions requiring a permit occur, the individual dwelling unit shall be equipped with carbon monoxide alarms located as required for new dwellings.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck.
2. Installation, alteration or repairs of plumbing or non-fuel fired mechanical systems.

Reason: Mechanical systems, including forced air units, dryers, water heaters, stoves, etc., are often fuel burning and therefore subject to leakage, should not be exempt from the requirement for carbon monoxide alarms.

Cost Impact: The code change proposal will increase the cost of construction. Will increase the cost of construction by modifying the current exemption to mechanical systems to include mechanical systems that are fuel-fired to have carbon monoxide detection and only exempt non fuel-fired mechanical systems.
R316.2.1 Mark on polystyrene foam insulation without flame retardants. Polystyrene foam insulation boards manufactured without flame retardants shall be marked in accordance with this section.

1. Each board shall be marked on both faces every 8 square feet in red 1/2" text with the following information:

- **WARNING - FIRE HAZARD**
- This product must only be installed below a minimum 3.5-inch thick concrete slab on grade.
- **NOT FOR VERTICAL OR ABOVE GRADE APPLICATIONS**
- This product contains NO flame retardants
- Not tested for flame spread or smoke development requirements of the model building codes

2. Each package shall be marked on at least two sides in red 1/2" text with the following information:

- **WARNING – COMBUSTIBLE MATERIAL**
- Keep away from ignition sources
- Maintain code required separation between product storage and structures under construction (minimum 30 feet).

Revise as follows:

R316.3 Surface burning characteristics. Unless otherwise allowed in Section R316.5, foam plastic, or foam plastic cores used as a component in manufactured assemblies, used in building construction shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 when tested in the maximum thickness and density intended for use in accordance with ASTM E84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

**Exception**: Exceptions:
1. Foam plastic insulation more than 4 inches (102 mm) thick shall have a flame spread index of not more than 75 and a smoke-developed index of not more than 450 where tested at a thickness of not more than 4 inches (102 mm), provided that the end use is approved in accordance with Section R316.6 using the thickness and density intended for use.

2. Polystyrene foam insulation boards with a maximum thickness of 2 inches (51 mm) where installed below a minimum 3.5-inch (89 mm) thick concrete slab-on-grade.

**Reason: Purpose of Proposal**

Polystyrene insulation (EPS and XPS) is commonly used in buildings to improve energy efficiency. To meet fire test building code requirements in the US and Canada all such insulation currently must contain flame retardant chemicals. In many cases, the tests do not accurately assess the fire safety of insulation.\(^1\) Research has shown that flame retardants used in polystyrene insulation below a slab-on-grade do not provide a significant fire-safety benefit. However, across their lifecycle these chemicals can harm human and ecosystem health.\(^2\)

This code change proposal would allow, but not require, the use of polystyrene insulation without flame retardants when installed below a concrete slab-on-grade at least 3-1/2 inches thick. The proposal was developed in response to the demand for healthier building materials from designers, developers and builders.

This proposed code change is nearly identical to the code change developed and advanced by the California Office of the State Fire Marshal for both the California Residential and the California Building Codes.

**Figure 1. Typical application where the proposed code change would apply.**

**Justification for Proposal**

Academic research and expert opinion that flame retardants are unnecessary for insulation below a slab-on-grade...
Neither an ignition source nor sufficient oxygen are present below a concrete slab-on-grade to support combustion. This proposal stipulates that flame retardant-free insulation and packaging be labeled with red 1/2” text lettering to ensure safe transport, storage, and proper installation.

Flammable liquids and gases, engineered wood products, and ABS pipe are all commonplace on construction sites. Other flame retardant-free polystyrene products such as cups and plates, packaging, and ice chests are stored and transported safely. Existing fire safety requirements in the fire and building codes, and in transportation regulations, adequately address necessary design and safety precautions for flame retardant-free polystyrene insulation.

Through the process described below, the California Office of the State Fire Marshal determined that chemical flame retardants provide no fire safety benefit for polystyrene insulation below a concrete slab-on-grade.

On the other hand, considerable peer-reviewed research has found that flame retardants used in building insulation are harmful to human and ecosystem health. Flame retardants have been linked to neurological impairment, hormone disruption, and aquatic toxicity. The flame retardant currently used in polystyrene insulation, PolyFR, is a brominated chemical that has not been well-studied nor proven safe. The manufacture, installation, demolition, landfilling, incineration, and recycling of flame-retarded polystyrene insulation can lead to environmental release of flame retardants and their toxic combustion by-products including brominated dioxins and furans. These chemicals can harm the health of construction workers and others exposed throughout the product life-cycle.

Human and ecosystem health and safety are within the ICC’s scope of concern. The language of intent of the 2018 IRC in Section R102.3 states: “The purpose of this code is...to safeguard the public safety, health and general welfare...from...hazards attributed to the built environment.” Action has been taken in ICC codes to limit exposure to lead, carbon monoxide, ozone depleting substances, volatile organic compounds, toxic compounds, and formaldehyde based on scientific evidence demonstrating that these materials present human health and environmental hazards.

**History of Proposal Development**

The California Office of the State Fire Marshal developed the language in this IRC proposal in collaboration with a large, multi-stakeholder Working Group on flammability standards for building insulation materials from 2014-2016. The Working Group recommended testing to determine the fire safety benefit of adding flame retardants to polystyrene insulation below a slab-on-grade.

The Office of the State Fire Marshal commissioned Oklahoma State University (OSU) to compare the flammability of polystyrene insulation in a subgrade installation with and without flame retardants. The CAL Fire/OSU Phase II Working Group reviewed and provided input on the testing criteria and results. Members of the Working Group representing multiple stakeholder perspectives were present for the testing. This group included scientists, NGOs, and representatives of flame-retardant manufacturers. Standard testing protocols had not been previously developed for combustible materials below a concrete slab-on-grade due to a lack of fire hazard in this application. Therefore, the Working Group, in collaboration with the OSU researchers, developed the specific tests and testing configurations.

The OSU researchers found:

- When installed below-slab, insulation without flame retardants presents no risk of fire spread to the building and will not endanger occupants or first responders.
- Adding flame retardants to polystyrene insulation does not significantly reduce peak heat release rates.
The time to ignition of flame-retardant free polystyrene was comparable to other combustible materials commonly found at construction sites.

Based on the result of the independent testing and following review by the California Building Standards Commission’s Code Advisory Committee and public comment, the Office of the State Fire Marshal proposed code changes to the California Building Standards Commission which are technically identical to this proposal for the IRC.

In summary, the California Office of the State Fire Marshal concluded, based on extensive stakeholder input, prior research, and transparent and independent testing by OSU, that flame retardant-free polystyrene foam insulation below slab-on-grade presents no fire risk, and the addition of flame retardants provides no fire-safety benefit. Flame retardant-free polystyrene insulation boards would create no more of a fire hazard than other combustible materials commonly found on construction sites, existing codes and standards that cover fire safety during construction.

**Precedent in Scandinavian countries**

Code updates in Norway have allowed polystyrene insulation board without flame retardants in buildings. A report by the Norwegian government in 2011 stated insulation placed underneath the concrete slab is considered to be the most fire safe solution. In the finished foundation, the insulation material is well protected from fire exposure. There is no advantage of using fire resistant materials or materials with flame retardants in this construction."

Similarly, a Risk Management Evaluation for EPS and XPS foam insulation stated: "By using thermal barriers it is possible to fulfill fire safety requirements in most uses in construction and buildings with EPS and XPS without a fire retardant do not represent a higher cost to the manufacturer. Our research of available data from these countries found no evidence of increased fire risk, insulation fires, or rollbacks of these code changes. Thus, this proposed code change has a significant precedent without increased fire risk.

**Summary Statement**

The proponents urge you to support this common-sense proposal. Human and ecosystem health will be improved. Fire fighters, building officials, and architects agree that builders should be able to choose flame retardant-free polystyrene insulation below a slab-on-grade.

**Bibliography:**

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Because this code change is not mandatory, there would be no required increased or decreased costs.

Proposal # 4622

RB131-19
IRCC®: R316.3, R316.3.1 (New), R316.3.2 (New)

Proponent: John Woestman, representing Extruded Polystyrene Foam Association (jwoestman@kellencompany.com)

2018 International Residential Code

Revise as follows:

R316.3 Surface burning characteristics. Unless otherwise allowed in Section R316.5, foam plastic, or foam plastic cores used as a component in manufactured assemblies, used in building construction shall comply with Section R316.3.1 or Section R316.3.2. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke developed index.

Add new text as follows:

R316.3.1 Foam plastic insulation 4” thick or less. Foam plastic insulation installed at 4” thickness or less shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 where tested in the maximum thickness and density intended for use in accordance with ASTM E84 or UL 723.

R316.3.2 Foam plastic insulation more than 4” thick. Foam plastic insulation installed at more than 4 inches (102 mm) thickness shall have a flame spread index of not more than 75 and a smoke-developed index of not more than 450 where tested at a thickness of not more than 4 inches (102 mm) in accordance with ASTM E84 or UL723, provided that the end use is approved in accordance with Section R316.6 using the thickness and density intended for use.

Reason: Proposed Section R316.3.2 is currently written as an exception. This exception allows foam plastic insulation intended to be installed in thickness greater than 4” to be tested in the Steiner Tunnel (ASTM E84) at a 4” thickness. This addresses the concern that Steiner Tunnels are generally physically limited to fire testing materials of not more than about 4” thickness. Rearranging and revising this section clarifies what fire testing is required.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

No technical changes are proposed.

Proposal # 5221
R316.3 Surface burning characteristics. Unless otherwise allowed in Section R316.5, foam plastic, or foam plastic cores used as a component in manufactured assemblies, used in building construction shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 when tested in the maximum thickness and density intended for use in accordance with ASTM E84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

Exception: Exceptions:

1. Foam plastic insulation more than 4 inches (102 mm) thick shall have a flame spread index of not more than 75 and a smoke-developed index of not more than 450 where tested at a thickness of not more than 4 inches (102 mm), provided that the end use is approved in accordance with Section R316.6 using the thickness and density intended for use.

2. Spray foam plastic insulation more than 4 inches (102 mm) in thickness shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450 where tested at a thickness of not less than 4 inches (102 mm), and at the density intended for use, provided that the spray foam plastic is separated from the interior of a building by an approved thermal barrier in accordance with Section R316.4.

Reason: Multiple successful NFPA 286 tests with a variety of spray foam plastic insulations with a 25 or less Flame Spread and thicknesses far exceeding 4 inches have demonstrated that any thickness will pass when covered with a prescriptive thermal barrier. Test have been burned with as much as 16 inches of spray foam in the NFPA 286 assembly (approx R-value over 100) and passed. The assembly construction is needlessly complicated to accommodate these excess thickness of foam, and only adds unnecessary expense to the test procedure. With the extensive available data, ICC Evaluation Services recognized there was no usefulness in full-scale testing of foam plastics with FS ±25 when covered with a prescriptive thermal barrier. ICC-ES began issuing code compliance evaluation reports using AC377 that permit these foam plastic insulations to be installed at any thickness when covered with a prescriptive thermal barrier. This provision is in the draft ICC 1100 Standard for Spray-applied Polyurethane Foam Plastic Insulation, which is in the final stages of approval for publication and has been approved for reference in the 2021 IBC (Code Proposal FS 155-18).

Cost Impact: The code change proposal will decrease the cost of construction
The proposal adds options to the code.
2018 International Residential Code

Revise as follows:

R316.4 Thermal barrier. Unless otherwise allowed in Section R316.5, foam plastic shall be separated from the interior of a building by an approved thermal barrier of not less than 1/2-inch (12.7 mm) gypsum wallboard; 23/32-inch (18.2 mm) wood structural panel or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

Reason: Thermal barriers are intended to protect foam plastics in case of fire from two hazards: (1) the foam plastic should not catch fire and reach flashover in 15 minutes when exposed to a fire similar to what can be expected in a room and (2) the foam plastic should not breach the thermal barrier for a period of 15 minutes so as to transmit high temperatures, fire and smoke from the concealed space (where the foam plastic is located) to the room (or vice versa). The NFPA 275 contains two tests that thermal barriers need to pass to demonstrate that they provide that protection: the temperature transmission fire test (which is a small scale ASTM E119 test conducted for 15 minutes) and the integrity fire test (that can be conducted using NFPA 286, FM 4880, UL 1715 or UL 1040). One of the key criteria of the integrity fire test is that the thermal barrier not reach flashover and not burn completely. If the integrity fire test is conducted as NFPA 286, the same criteria are used as shown in section 302 of the IRC for NFPA 286 (and equivalent criteria are used for the other tests).

It has been shown that a 0.5 inch gypsum wallboard is equivalent to a material that meets the test requirements of NFPA 275 and provides the appropriate fire protection from both fire penetration and fire integrity. On the other hand, tests conducted to NFPA 286 show clearly that a 23/32 inch wood structural panel burns and is not equivalent: it clearly reaches flashover and will lead to the foam plastic insulation burning. Therefore, it does not provide equivalent protection to a thermal barrier or to a 0.5 inch gypsum board.

Note that the language in the code states that the thermal barrier must be an approved material but gives two exceptions to a material that passes NFPA 275, clearly suggesting that they are equivalent: a 0.5 inch gypsum board (which are equivalent) and a thin wood product, which is easily combustible and clearly not equivalent to gypsum board.

Thermal barriers are required in the IRC to protect building occupants from fires associated with foam plastics (as separated from the building interior, R302.8 and R316) and structural insulated panels (SIPs) in walls (R610.5.6). The IBC (section 2603.4) describes a thermal barrier and also allows a wood product as an untested alternate, but the exception in IBC is heavy timber and not a thin wood panel.

Cost Impact: The code change proposal will increase the cost of construction
This will prohibit the use of thin wood as a thermal barrier.
Proponent: Mike Fischer, Kellen Company, representing The Center for the Polyurethanes Industry of the American Chemistry Council (mfischer@kellencompany.com)

2018 International Residential Code

Revise as follows:

R316.5.13 Floors. The thermal barrier specified in Section R316.4 is not required to be installed on the walking surface of a structural floor system that contains foam plastic insulation where the foam plastic is covered by not more less than a nominal 1/2-inch-thick (12.7 mm) wood structural panel or equivalent. The thermal barrier specified in Section R316.4 is required on the underside of the structural floor system that contains foam plastic insulation where the underside of the structural floor system is exposed to the interior of the building.

Reason: The current code contains an error by specifying a maximum thickness for wood structural panel used to cover foam plastic insulation in floor systems. The code should establish a minimum thickness for protection.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal fixes an editorial flaw in the current text.

Proposal # 5611
2018 International Residential Code

Revise as follows:

R317.1 Location required. Protection of wood and wood-based products from decay shall be provided in the following locations by the use of naturally durable wood or wood that is preservative-treated in accordance with AWPA U1.

1. Wood joists or the bottom of a wood structural floor where closer than 18 inches (457 mm) or wood girders where closer than 12 inches (305 mm) to the exposed ground in crawl spaces or unexcavated area located within the periphery of the building foundation.

2. Wood framing members that rest on concrete or masonry exterior foundation walls and are less than 8 inches (203 mm) from the exposed ground.

3. Sills and sleepers on a concrete or masonry slab that is in direct contact with the ground unless separated from such slab by an impervious moisture barrier.

4. The ends of wood girders entering exterior masonry or concrete walls having clearances of less than 1/2 inch (12.7 mm) on tops, sides and ends.

5. Wood siding, sheathing and wall framing on the exterior of a building having a clearance of less than 6 inches (152 mm) from the ground or less than 2 inches (51 mm) measured vertically from concrete steps, porch slabs, patio slabs and similar horizontal surfaces exposed to the weather.

6. Wood structural members supporting moisture-permeable floors or roofs that are exposed to the weather, such as concrete or masonry slabs, unless separated from such floors or roofs by an impervious moisture barrier.

7. Wood furring strips or other wood framing members attached directly to the interior of exterior masonry walls or concrete walls below grade except where an approved vapor retarder is applied between the wall and the furring strips or framing members.

8. Portions of wood structural members that form the structural supports of buildings, balconies, porches or similar permanent building appurtenances where those members are exposed to the weather without adequate protection from a roof, eave, overhang or other covering that would prevent moisture or water accumulation on the surface or at joints between members.

Exception: Sawn lumber used in buildings located in a geographical region where experience has demonstrated that climatic conditions preclude the need to use naturally durable or perservative-treated wood where the structure is exposed to the weather.

Delete without substitution:

R317.1.3 Geographical areas. In geographical areas where experience has demonstrated a specific need, approved naturally durable or pressure preservative treated wood shall be used for those portions of wood members that form the structural supports of buildings, balconies, porches or similar permanent building appurtenances where those members are exposed to the weather without adequate protection from a roof, eave, overhang or other covering that would prevent moisture or water accumulation on the surface or at joints between members. Depending on local experience, such members typically include:

1. Horizontal members such as girders, joists and decking.
2. Vertical members such as posts, poles and columns.
3. Both horizontal and vertical members.
**R317.1.5 Exposed glued-laminated timbers.** The portions of glued-laminated timbers that form the structural supports of a building or other structure and are exposed to weather and not properly protected by a roof, eave or similar covering shall be pressure treated with preservative, or be manufactured from naturally durable or preservative-treated wood.

**Reason:** The proposed change does several things:
First, the existing section R317.1.3 (Geographical areas) seems to require wood members exposed to the weather to be treated or naturally durable only if a need is demonstrated. It makes more sense to require them to be protected outright and have an exception for arid geographical regions where it has been demonstrated that the protection is not needed. Relocating it to the list of locations in R317.1 and providing an exception to the item will be clearer. The text of R317.1.3 was moved to the new item 8, except for the descriptors about horizontal and vertical members in the three items at the end of the current section, which seem more appropriate for the commentary to the code.

The wording of the proposed exception to new item 8 is the same as the wording of the parallel exception in Section 2304.12.2.3 of the IBC, with the addition of the words "Sawn lumber used in" at the beginning and replacing the words "durable materials" with "naturally durable or preservative-treated wood" for better language without changing the meaning. The proposal limits the “geographic areas” exception to sawn lumber and excludes engineered wood products such as glued-laminated timber. Under the current code structure, glued-laminated timbers are covered under their own section R317.1.5 and it is commonly understood that the provisions of current Section R317.1.3 are not applicable to them anyway. Presumably all engineered wood products using adhesives should be protected when exposed to the weather regardless of climate or geographic locations, and manufacturers' recommendations would require it.

It is intended to be a new item 8 with the same hierarchy as the current seven items preceding it, and the Exception is intended to be indented under new item 8 so that it only applies to item 8.

Finally, since the proposed item 8 is broad enough to include the current requirement in R317.1.5 for glued-laminated timber, R317.1.5 can also be deleted.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The application of the current code section may vary depending on interpretation. It is not intended to change the requirements from the most common interpretations, therefore there will be no difference in cost of construction.

Proposal # 4687
RB137-19
IRC®: R317.1, R317.1.4
Proponent: Paul Coats, representing American Wood Council (pcoats@awc.org)

2018 International Residential Code
Revise as follows:

R317.1 Location required. Protection of wood and wood-based products from decay shall be provided in the following locations by the use of naturally durable wood or wood that is preservative-treated in accordance with AWPA U1.

1. Wood joists or the bottom of a wood structural floor where closer than 18 inches (457 mm) or, wood girders where closer than 12 inches (305 mm) to the exposed ground, in crawl spaces or unexcavated area located within the periphery of the building foundation, wood joists or the bottom of a wood structural floor where closer than 18 inches (457 mm) to exposed ground, wood girders where closer than 12 inches (305 mm) to exposed ground, and wood columns where closer than 8 inches (204 mm) to exposed ground.
2. Wood framing members, including columns, that rest on concrete or masonry exterior foundation walls and are less than 8 inches (203 mm) from the exposed ground.
3. Sills and sleepers on a concrete or masonry slab that is in direct contact with the ground unless separated from such slab by an impervious moisture barrier.
4. The ends of wood girders entering exterior masonry or concrete walls having clearances of less than 1/2 inch (12.7 mm) on tops, sides and ends.
5. Wood siding, sheathing and wall framing on the exterior of a building having a clearance of less than 6 inches (152 mm) from the ground or less than 2 inches (51 mm) measured vertically from concrete steps, porch slabs, patio slabs and similar horizontal surfaces exposed to the weather.
6. Wood structural members supporting moisture-permeable floors or roofs that are exposed to the weather, such as concrete or masonry slabs, unless separated from such floors or roofs by an impervious moisture barrier.
7. Wood furring strips or other wood framing members attached directly to the interior of exterior masonry walls or concrete walls below grade except where an approved vapor retarder is applied between the wall and the furring strips or framing members.
8. Wood columns in contact with basement floor slabs unless supported by concrete piers or metal pedestals projecting at least 1 inch (25 mm) above the concrete floor and separated from the concrete pier by an impervious moisture barrier.

Delete without substitution:

R317.1.4 Wood columns. Wood columns shall be approved wood of natural decay resistance or approved pressure preservative-treated wood.

Exceptions:

1. Columns exposed to the weather or in basements where supported by concrete piers or metal pedestals projecting 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth and the earth is covered by an approved impervious moisture barrier.
2. Columns in enclosed crawl spaces or unexcavated areas located within the periphery of the building where supported by a concrete pier or metal pedestal at a height more than 8 inches (203 mm) from exposed earth and the earth is covered by an impervious moisture barrier.
3. Deck posts supported by concrete piers or metal pedestals projecting not less than 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth.

**Reason:** Current Section R317.1.4 on wood column protection is unnecessarily confusing and contains errors in syntax, making it difficult to apply.

Current Exceptions 1 and 2: Current Exception 1 seems to exempt all columns exposed to the weather, which is not the intent. The rest of Exception 1 has criteria which conflicts with the current IBC and also seems to conflict with Exception 2—does the elevation of concrete piers and metal pedestals need to be 6 inches or 8 inches? It may be confusing when comparing the exceptions. In addition, the parallel section in the IBC, Section 2304.12.2.2, says nothing about covering the exposed ground in the crawl space with an impervious moisture barrier as a criterium for column protection, and sets the clearance for the bottom of the column at 8 inches above exposed earth, the same as is required for framing on exterior walls.

Current Exception 3: Current Exception 3 seems to exempt any deck posts that are supported by piers or pedestals extending 1 inch above concrete or 6 inches above exposed earth. But it would seem good policy that any deck post exposed to the weather should be treated regardless of clearance to a slab or ground.

Current charging language: The charging language in R317.1.4 requires all columns, regardless of location, to be treated unless they fit into an exception. Interior columns completely protected from the weather, such as heavy timber columns in the interior of the building or built-up columns in walls, are technically required to be treated since they don’t fit into any exception. This is not the intent of the code.

This proposal attempts to incorporate wood columns in the general “location” items of R317.1 and eliminate the separate confusing columns section altogether:

Revisions to R317.1 item 1: Similar to floor framing and girders, columns are given a required clearance from exposed earth in crawl spaces, a clearance which is generally consistent with current Exception 2 except the requirement to cover the exposed ground with an impervious moisture barrier is dropped. The reason this requirement was dropped is because there is no such requirement in the parallel sections of the IBC (2304.12.2.2), and it seems that as long as a conservative clearance is required, provisions for moisture barriers over exposed earth in a crawl space should be governed by the crawl space section of the code (R408 Under-Floor Spaces, which has provisions for moisture barriers). The wording of item 1 is rearranged to retain readability with the addition of the new provision for columns.

Revision to R317.1 item 2: Including columns here specifically with other “wood framing members” seems prudent since the columns section is proposed for deletion. However, it may not be necessary since wood columns would normally be considered a wood framing member.

New item 8 to R317.1: This new item is necessary to preserve the reduced clearance for columns above basement floor slabs. It provides for as little as 1 inch of clearance if on a metal pedestal (consistent with current Exception 1 to R317.1.4), and 1 inch of clearance on a concrete pier if it is separated from the pier by an impervious moisture barrier, since concrete is porous and will allow wicking of moisture more readily (this consistent with current Exception 1 of R317.1.4 and also with IBC Section 2304.12.2.2 Exception 2).

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. These proposed revisions correct errors to match how the code is currently applied. Therefore, no cost increase is anticipated.
2018 International Residential Code

Delete and substitute as follows:

R317.1.4 Wood columns. Wood columns shall be approved wood of natural decay resistance or approved pressure-preservative-treated wood.

Exceptions:

1. Columns exposed to the weather or in basements where supported by concrete piers or metal pedestals projecting 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth and the earth is covered by an approved impervious moisture barrier.

2. Columns in enclosed crawl spaces or unexcavated areas located within the periphery of the building where supported by a concrete pier or metal pedestal at a height more than 8 inches (203 mm) from exposed earth and the earth is covered by an impervious moisture barrier.

3. Deck posts supported by concrete piers or metal pedestals projecting not less than 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth.

R317.1.4 Posts or columns Posts and columns supporting permanent structures and supported by a concrete or masonry slab or footing that is in direct contact with the earth shall be of naturally durable or preservative-treated wood.

Exceptions:

1. Are not exposed to the weather, or are protected by a roof, eave, overhang, or other covering where exposed to the weather.

2. Are supported by concrete piers or metal pedestals projected not less than 1 inch (25 mm) above the slab or deck and the posts and columns are separated from the concrete pier by an impervious moisture barrier.

3. Are located not less than 8 inches (203 mm) above exposed earth.

Reason: This proposal completely replaces the current text of R317.1.4 with the current provisions of Section 2304.12.2.2 from the IBC. The proposed text is exactly what appears in the current section 2304.12.2.2 of the IBC. The current IRC Section R317.1.4 on wood column protection is unnecessarily confusing and contains errors in syntax, making it difficult to apply. Current charging language requires all wood columns to be preservative treated and the exceptions are inadequate. Current Exception #1 erroneously references "columns exposed to the weather", which is not the intent. Rather it should read "Columns NOT exposed to weather...". The rest of Exception 1 has criteria which conflicts with the current IBC and also may conflict with Exception 2. The parallel section in the IBC says nothing about impervious moisture barriers on exposed ground. In addition, Exception 3 would seem to permit deck posts exposed to the weather to be untreated, as long as they are elevated off of the ground. Also, the current section does not contain an adequate exception for interior columns.

This proposal is one alternative to correcting the errors in this section.
**Bibliography:** None.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
These proposed revisions correct errors to match how the code is currently applied. Therefore, no cost increase is anticipated.

Proposal #: 5141

RB138-19
Proponent: Steven Mickley, representing American Institute of Building Design (steve.mickley@aibd.org)

2018 International Residential Code

SECTION R320
ACCESSIBILITY

Revise as follows:

R320.1 Scope. Where there are four or more dwelling units or sleeping units in a single structure, the provisions of Chapter 11 of the International Building Code for Group R-3 shall apply. For the purpose of applying the requirements of Chapter 11 of the International Building Code, guestrooms shall be considered to be sleeping units.

Exceptions:

1. A multistory dwelling unit that is not provided with elevator service is not required to comply with this section.
2. Owner-occupied lodging houses with five or fewer guestrooms constructed in accordance with the International Residential Code are not required to comply with this section.

Delete without substitution:

R320.1.1 Guestrooms. A dwelling with guestrooms shall comply with the provisions of Chapter 11 of the International Building Code for Group R-3. For the purpose of applying the requirements of Chapter 11 of the International Building Code, guestrooms shall be considered to be sleeping units.

Exception: Owner-occupied lodging houses with five or fewer guestrooms constructed in accordance with the International Residential Code are not required to be accessible.

Add new definition as follows:

MULTISTORY UNIT. A dwelling unit or sleeping unit with habitable space located on more than one story.

Reason: Chapter 11 of the IBC exempts owner-occupied lodging houses with no more than five sleeping units and multistory dwelling units not provided with elevator service. IRC, Section 320 currently only mentions lodging houses being exempt. Therefore, this proposed amendment is intended to clarify, without the designer having to refer to both Section 320 of the IRC and Chapter 11 of the IBC, multistory dwelling units not provided with elevator service are not required to comply.

The following illustration from the Fair Housing Act Design Manual visually depicts which units are "covered" by the act, and which are "not covered." It also depicts the scope of Chapter 11 of the IBC and the intent of this amendment.
**Bibliography:** International Building Code, International Code Council, published in September 2018

**Cost Impact:** The code change proposal will decrease the cost of construction
This proposal will decrease the cost of design and construction by eliminating potential misinterpretation and unnecessary regulation.

---

**Proposal # 5528**

RB139-19
LIVE/WORK UNIT. A dwelling unit or sleeping unit in which a significant portion of the space includes a nonresidential use that is operated by the tenant.

SLEEPING UNIT. A single unit that provides rooms or spaces for one or more persons, includes permanent provisions for sleeping and can include provisions for living, eating and either sanitation or kitchen facilities but not both. Such rooms and spaces that are also part of a dwelling unit are not sleeping units.

Revise as follows:

SECTION R320
ACCESSIBILITY

R320.1 Scope. Where there are four or more dwelling units or sleeping units in a single structure, the provisions of Chapter 11 of the International Building Code for Group R-3 shall apply.

   Exception: Owner-occupied lodging houses with five or fewer guestrooms are not required to be accessible.

Delete without substitution:

R320.1.1 Guestrooms. A dwelling with guestrooms shall comply with the provisions of Chapter 11 of the International Building Code for Group R-3. For the purpose of applying the requirements of Chapter 11 of the International Building Code, guestrooms shall be considered to be sleeping units.

   Exception: Owner-occupied lodging houses with five or fewer guestrooms constructed in accordance with the International Residential Code are not required to be accessible.

Add new text as follows:

R320.2 Live/work units. In live/work units, the nonresidential portion shall be accessible in accordance with Sections 419.7 and 419.9 of the International Building Code. In a structure where there are four or more live/work units, the dwelling portion of the live/work unit shall comply with Section 1107.6.2.1 of the International Building Code.

Reason: The accessibility provisions have not kept up with the revised scope of the IRC. This is the scope - R101.2 Scope. The provisions of this code shall apply to the construction, alteration, movement, enlargement, replacement, repair, equipment, use and occupancy, location, removal and demolition of detached one- and two-family dwellings and townhouses not more than three stories above grade plane in height with a separate means of egress and their accessory structures not more than three stories above grade plane in height.

Exception: The following shall be permitted to be constructed in accordance with this code where provided with a residential fire sprinkler system complying with Section P2904:
1. Live/work units located in townhouses and complying with the requirements of Section 419 of the International Building Code.

2. Owner-occupied lodging houses with five or fewer guestrooms.

3. A care facility with five or fewer persons receiving custodial care within a dwelling unit.

4. A care facility with five or fewer persons receiving medical care within a dwelling unit.

5. A care facility for five or fewer persons receiving care that are within a single-family dwelling.

The scope in the IRC of the transient lodging is limited to owner occupied with 5 or fewer guestrooms, so there will be no larger facilities. Guestrooms are sleeping units which is covered in R320.1, so a separate section that start by applying to something that is not permitted just to get the exception is not needed. You can just apply the exception to R310.1. This does coordinate with IBC Section 1103.2.11.

1103.2.11 Residential Group R-1. Buildings of Group R-1 containing not more than five sleeping units for rent or hire that are also occupied as the residence of the proprietor are not required to comply with this chapter.

For Live work units, the IBC has

419.7 Accessibility. Accessibility shall be designed in accordance with Chapter 11 for the function served.

419.9 Plumbing facilities. The nonresidential area of the live/work unit shall be provided with minimum plumbing facilities as specified by Chapter 29, based on the function of the nonresidential area. Where the nonresidential area of the live/work unit is required to be accessible by Section 1107.6.2.1, the plumbing fixtures specified by Chapter 29 shall be accessible.

1107.6.2.1 Live/work units. In live/work units constructed in accordance with Section 419, the nonresidential portion is required to be accessible. In a structure where there are four or more live/work units intended to be occupied as a residence, the residential portion of the live/work unit shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

It is proposed to add a reference to this language to the IRC for consistency for accessibility requirements for Live/work units.

Since the terms ‘sleeping units’ and ‘live/work units’ are used in the IRC, in this section and others. It is proposed to add the definitions currently found in the IBC.

This proposal is submitted by the ICC Building Code Action Committee (BCAC). BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org_codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This will make the IRC requirements consistent with the IBC for owner-occupied lodging houses and live/work
units.
R309.3 Flood hazard areas. For buildings located in flood hazard areas as established by Table R301.2(1), garage floors shall be one of the following:

1. Elevated to or above the design flood required lowest floor elevation as determined in accordance with Section R322.
2. Located below the design flood required lowest floor elevation provided that the floors are at or above grade on not less than one side, are used solely for parking, building access or storage, meet the requirements of Section R322 and are otherwise constructed in accordance with this code.

R322.1.6 Protection of mechanical, plumbing and electrical systems. Electrical systems, equipment and components; heating, ventilating, air-conditioning; plumbing appliances and plumbing fixtures; duct systems; and other service equipment shall be located at or above the elevation required in Section R322.2 or R322.3. If replaced as part of a substantial improvement, electrical systems, equipment and components; heating, ventilating, air-conditioning and plumbing appliances and plumbing fixtures; duct systems; and other service equipment shall meet the requirements of this section. Systems, fixtures, and equipment and components shall not be mounted on or penetrate through walls intended to break away under flood loads.

Exception: Locating electrical systems, equipment and components; heating, ventilating, air-conditioning; plumbing appliances and plumbing fixtures; duct systems; and other service equipment is permitted below the elevation required in Section R322.2 or R322.3 provided that they are designed and installed to prevent water from entering or accumulating within the components and to resist hydrostatic and hydrodynamic loads and stresses, including the effects of buoyancy, during the occurrence of flooding to the design flood required elevation in accordance with ASCE 24. Electrical wiring systems are permitted to be located below the required elevation provided that they conform to the provisions of the electrical part of this code for wet locations.

R322.2.1 Elevation requirements.

1. Buildings and structures in flood hazard areas, including flood hazard areas designated as Coastal A Zones, shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.
2. In areas of shallow flooding (AO Zones), buildings and structures shall have the lowest floor (including basement) elevated to a height above the highest adjacent grade of not less than the depth number specified in feet (mm) on the FIRM plus 1 foot (305 mm), or not less than 3 feet (915 mm) if a depth number is not specified.
3. Basement floors that are below grade on all sides shall be elevated to or above base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.

Exception: Enclosed areas below the design flood elevation required in this section, including basements with floors that are not below grade on all sides, shall meet the requirements of Section R322.2.2.
R322.2.2 Enclosed area below design flood-required elevation. Enclosed areas, including crawl spaces, that are below the design flood elevation required in Section R322.2.1 shall:

1. Be used solely for parking of vehicles, building access or storage.
2. Be provided with flood openings that meet the following criteria and are installed in accordance with Section R322.2.2.1:
   2.1. The total net area of nonengineered openings shall be not less than 1 square inch (645 mm²) for each square foot (0.093 m²) of enclosed area where the enclosed area is measured on the exterior of the enclosure walls, or the openings shall be designed as engineered openings and the construction documents shall include a statement by a registered design professional that the design of the openings will provide for equalization of hydrostatic flood forces on exterior walls by allowing for the automatic entry and exit of floodwaters as specified in Section 2.7.2.2 of ASCE 24.
   2.2. Openings shall be not less than 3 inches (76 mm) in any direction in the plane of the wall.
   2.3. The presence of louvers, blades, screens and faceplates or other covers and devices shall allow the automatic flow of floodwater into and out of the enclosed areas and shall be accounted for in the determination of the net open area.

R322.2.2.1 Installation of openings. The walls of enclosed areas shall have openings installed such that:

1. There shall be not less than two openings on different sides of each enclosed area; if a building has more than one enclosed area below the design flood elevation, each area shall have openings.
2. The bottom of each opening shall be not more than 1 foot (305 mm) above the higher of the final interior grade or floor and the finished exterior grade immediately under each opening.
3. Openings shall be permitted to be installed in doors and windows; doors and windows without installed openings do not meet the requirements of this section.

R322.3.2 Elevation requirements.

1. Buildings and structures erected within coastal high-hazard areas and Coastal A Zones, shall be elevated so that the bottom of the lowest horizontal structural members supporting the lowest floor, with the exception of piling, pile caps, columns, grade beams and bracing, is elevated to or above the base flood elevation plus 1 foot (305 mm) or the design flood elevation, whichever is higher.
2. Basement floors that are below grade on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.
5. Walls and partitions enclosing areas below the design flood elevation required in this section shall meet the requirements of Sections R322.3.5 and R322.3.6.

R322.3.5 Walls below design flood-required elevation. Walls and partitions are permitted below the elevated floor elevation required in Section R322.3.2, provided that such walls and partitions are not part of the structural support of the building or structure and:

1. Electrical, mechanical and plumbing system components are not to be mounted on or penetrate through walls that are designed to break away under flood loads; and
2. Are constructed with insect screening or open lattice; or
3. Are designed to break away or collapse without causing collapse, displacement or other structural damage to the elevated portion of the building or supporting foundation system. Such
walls, framing and connections shall have a resistance of not less than 10 (479 Pa) and not more than 20 pounds per square foot (958 Pa) as determined using allowable stress design; or

4. Where wind loading values of this code exceed 20 pounds per square foot (958 Pa), as determined using allowable stress design, the construction documents shall include documentation prepared and sealed by a registered design professional that:

4.1. The walls and partitions below the design flood required elevation have been designed to collapse from a water load less than that which would occur during the base flood.

4.2. The elevated portion of the building and supporting foundation system have been designed to withstand the effects of wind and flood loads acting simultaneously on structural and nonstructural building components. Water-loading values used shall be those associated with the design flood. Wind-loading values shall be those required by this code.

5. Walls intended to break away under flood loads as specified in Item 3 or 4 have flood openings that meet the criteria in Section R322.2.2, Item 2.

R322.3.6 Enclosed areas below design flood required elevation. Enclosed areas below the design flood elevation required in Section R322.3.2 shall be used solely for parking of vehicles, building access or storage.

R322.3.7 Stairways and ramps. Stairways and ramps that are located below the lowest floor elevations specified in Section R322.3.2 shall comply with one or more of the following:

1. Be designed and constructed with open or partially open risers and guards.
2. Stairways and ramps not part of the required means of egress shall be designed and constructed to break away during design flood conditions without causing damage to the building or structure, including foundation.
3. Be retractable, or able to be raised to or above the lowest flood elevation, provided that the ability to be retracted or raised prior to the onset of flooding is not contrary to the means of egress requirements of the code.
4. Be designed and constructed to resist flood loads and minimize transfer of flood loads to the building or structure, including foundation.

Areas below stairways and ramps shall not be enclosed with walls below the design flood elevation required in Section R322.3.2 unless such walls are constructed in accordance with Section R322.3.5.

Reason: The primary aspect of elevated homes in flood hazard areas that contributes to reducing damage is the elevation of the lowest floor (R322.2.1) or lowest horizontal structural member of the lowest floor in Zone V and Coastal A Zones (R322.3.2) relative to the base flood elevation. The higher the floor, the lower the risk (and the lower are NFIP flood insurance premiums). To ensure the same level of protection is applied to all aspects of dwellings, Section R322.1.6 requires mechanical, plumbing and electrical equipment to be located at or above the required elevations, and R322.1.8 requires use of flood damage-resistant materials below the required elevations. This same level of protection should apply to enclosures and walls below the required elevations. Currently, the level of protection for enclosures and walls is at the design flood elevation, which may be lower than the lowest floor elevations required in R322.2.1 and R322.3.2. This proposal is consistent with ASCE 24, in which each table specifying elevations refers not to the elevation of the flood, but the required elevation of the lowest floor (ow lowest horizontal structural member of the lowest floor). This proposal is consistent with the NFIP regulations which, in Section 60.3(c)(5) specifies... “fully enclosed areas below the lowest floor…” and Section 60.3(e)(5) which specifies..."space below the lowest floor either free of obstruction or constructed with non-supporting breakaway walls ...".

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Most enclosures below elevated buildings in flood hazard areas are constructed with all elements required for enclosures applied below the elevated lowest floor, thus no change in cost of construction. There may be a
slight increase in cost in those rare situations where someone determines the DFE/BFE and “precisely” applies the regulations up to that elevation rather than up to the actual elevation of the lowest floor.

Proposal # 4437

RB141-19
2018 International Residential Code

Revise as follows:

R322.2.1 Elevation requirements.

1. Buildings and structures in flood hazard areas, not including flood hazard areas designated as Coastal A Zones, shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.

2. In areas of shallow flooding (AO Zones), buildings and structures shall have the lowest floor (including basement) elevated to a height above the highest adjacent grade of not less than the depth number specified in feet (mm) on the FIRM plus 1 foot (305 mm), or not less than 3 feet (915 mm) if a depth number is not specified.

3. Basement floors that are below grade on all sides shall be elevated to or above base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.

Exception: Enclosed areas below the design flood elevation, including basements with floors that are not below grade on all sides, shall meet the requirements of Section R322.2.2.

Reason: Two successful changes were approved in the 2015 code development cycle. One change modified the elevation requirement by adding 1 foot (freeboard) uniformly into R322, and one change made buildings in designated Coastal A Zones subject to the requirements of R322.3. The clear intent of the second change is to require buildings in Coastal A Zones to comply with R322.3. This is also clear in both R322.2 and R322.3. However, the combination of the two changes approved for R322.2.1 resulted in misleading phrasing. As written, buildings in flood hazard areas designated as Coastal A Zones are subject to the elevation requirements of both R322.2.1 (item #1) and R322.3.2. This proposal adds the word "not" in the first item, removing confusion by explicitly stating buildings in flood hazard areas designated as Coastal A Zones are not addressed by R322.2.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

No additional cost. This proposal does not change any requirements for buildings in flood hazard areas designated as Coastal A Zones, which must comply with R322.3.
2018 International Residential Code

Revise as follows:

R322.2.3 Foundation design and construction. Foundation walls for buildings and structures erected in flood hazard areas shall meet the requirements of Chapter 4. Plain masonry walls are not permitted unless designed to account for flood loads.

**Exception:** Unless designed in accordance with Section R404:

1. The unsupported height of 6-inch (152 mm) plain masonry walls shall be not more than 3 feet (914 mm).
2. The unsupported height of 8-inch (203 mm) plain masonry walls shall be not more than 4 feet (1219 mm).
3. The unsupported height of 8-inch (203 mm) reinforced masonry walls shall be not more than 8 feet (2438 mm).

For the purpose of this exception, unsupported height is the distance from the finished grade of the under-floor space to the top of the wall.

**Reason:** Section R322.2 applies in flood hazard areas other than coastal high hazard areas (Zone V) and coastal A zones. These are flood hazard areas along waterways, around lakes, and inland of the Zone V or Limit of Moderate Wave Action (if delineated). This proposal removes the exception to allow prescriptive heights for unsupported masonry walls and therefore requires all foundations in flood hazard areas to meet the requirements of Chapter 4. The proposal also would not allow plain masonry walls. The proposal also clarifies that all foundations, not just foundation walls, must meet Chapter 4 requirements.

The wall height limitations in R322.2.3 are based on analyses performed in 1998 for a range of flood depths and flood velocities. FEMA re-examined those limitations in 2013 after observing foundation damage documented in FEMA’s post-disaster Mitigation Assessment Team reports which identified failure of unreinforced masonry (URM) walls under flood loads (see FEMA P-765, Midwest Floods of 2008 in Iowa and Wisconsin) and design wind loads (see FEMA P-908, Spring 2011 Tornadoes). MAT teams deployed after Hurricane Sandy documented numerous examples of failed unreinforced and lightly reinforced walls sections in areas shown on Flood Insurance Rate Maps as Zone A, both with and without evidence of moderate waves. Analyses performed in 2013 for a range of wall types and heights, and a range of flood conditions, demonstrated the importance of reinforcement. If this proposal passes, FEMA will provide commentary with guidance for foundations in special flood hazard areas where velocities may exceed 5 fps.

When wind and flood loads are applied under Allowable Stress Design (ASD) Load Combination 7 per ASCE 7-10 Section 2.4.2 (2), net tension results at the top of the foundation wall from the minimum ASCE 7-10 basic wind speed of 115 mph (Exposure Category B). Higher design wind speeds result in greater uplift. The design criteria of ACI-530 Section 2.2.4 specifies that the tensile strength of unreinforced masonry shall be neglected when subjected to axial tension forces. Accordingly, unreinforced wall sections analyzed with net axial tension at
the top of wall from the combined effects of wind and flood loading have been disallowed. ACI-530 commentary to Section 2.2.4 further stipulates, “Net axial tension in unreinforced masonry walls due to axially applied load are not permitted. If axial tension develops in walls due to uplift of connected roofs or floors, the walls must be reinforced to resist the tension. Compressive stress from dead load can be used to offset axial tension.”

**Cost Impact:** The code change proposal will increase the cost of construction

The code change proposal will increase the cost of construction for a limited set of buildings that might have perimeter wall foundations that would fall within the height and wall thickness limits in the exception. However, the likelihood of failure of those foundations under anticipated flood loads will be reduced, and thus decreases future costs associated with rebuilding after flood and flood/high wind events.
2018 International Residential Code

Revise as follows:

R322.3.2 Elevation requirements.

1. Buildings and structures erected within coastal high-hazard areas and Coastal A Zones shall be elevated so that the bottom of the lowest horizontal structural members supporting the lowest floor, with the exception of piling, pile caps, columns, grade beams and bracing, is elevated to or above the base flood elevation plus 1 foot (305 mm) or the design flood elevation, whichever is higher. Where stem wall foundations in Coastal A Zones meet the requirements of R322.3.3, the bottom of the lowest horizontal structural member supporting the lowest floor is the bottom of the capping slab.

2. Basement floors that are below grade on all sides are prohibited.

3. The use of fill for structural support is prohibited.

4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.

5. Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.5 and R322.3.6.

Reason: Section R322.3.2 requires the bottom of the lowest horizontal structural member supporting the lowest floor to be at or above a specific elevation. The basic foundation requirement, in Section R322.3.3, specifies pilings or columns, which minimize obstructions and allow floodwater to pass under elevated buildings. When Coastal A Zones, where designated, were added to Section R322.3 in recognition of the damage even moderate waves can cause, along with scour, the exception to permit backfilled stem wall foundations was added to Section R322.3.3. Unlike open piling and column foundations, it is not clear where the lowest horizontal structural member is to be measured on a stem wall foundation. This proposal clarifies the bottom of the lowest horizontal structural member is the bottom of the capping slab.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal provides clarification to an existing requirement.
2018 International Residential Code

Revise as follows:

**R322.3.3 Foundations.** Buildings and structures erected in coastal high-hazard areas and Coastal A Zones shall be supported on pilings or columns and shall be adequately anchored to such pilings or columns and shall comply with the following:

1. **columns.** The space below the elevated building shall be either free of obstruction or, if enclosed with walls, the walls shall meet the requirements of Section R322.3.5.

2. Pilings shall have adequate soil penetrations to resist the combined wave and wind loads (lateral and uplift). Water loading values used shall be those associated with the design flood. Wind loading values shall be those required by this code. Pile and pile embedment shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the piling.

3. Columns and their supporting foundations shall be designed to resist combined wave and wind loads, lateral and uplift, and shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the columns. Pile systems design and installation shall be certified in accordance with Section R322.3.9. Spread footing, mat, raft or other foundations that support columns shall not be permitted where soil investigations that are required in accordance with Section R401.4 indicate that soil material under the spread footing, mat, raft or other foundation is subject to scour or erosion from wave-velocity flow conditions. If permitted, spread footing, mat, raft or other foundations that support columns shall be designed in accordance with ASCE 24.

4. Flood and wave loads shall be those associated with the design flood. Wind loads shall be those required by this code.

5. Foundation designs and construction documents shall be prepared and sealed in accordance with Section R322.3.9.

**Exception:** In Coastal A Zones, stem wall foundations supporting a floor system above and backfilled with soil or gravel to the underside of the floor system shall be permitted provided that the foundations are designed to account for wave action, debris impact, erosion and local scour. Where soils are susceptible to erosion and local scour, stem wall foundations shall have deep footings to account for the loss of soil.

**Reason:** Section R322.3.3 allows the use of pilings or columns, but the way the requirements are phrased makes it appear they apply only to pilings, without equivalent specificity for columns. Columns must also be designed to account for wave and wind loads and the effects of scour. The primary object of this proposal is to provide that specificity. Second, the current text is long, so the proposal breaks it into distinct numbered items which makes it easier to read.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. No cost impact associated with the added text for columns because the text is clarifying only and column foundations already are required to be designed by registered design professionals who should always evaluate whether sites have erodible soils subject to scour as part of the design process.

Proposal # 4443
2018 International Residential Code

Add new definition as follows:

**STORM SHELTER.** A building, structure or portion thereof, constructed in accordance with ICC 500 and designated for use during a severe wind storm event, such as a hurricane or tornado.

Add new text as follows:

**R106.1.5 Information on storm shelters.** Construction documents for storm shelters shall include the information required in ICC 500.

**SECTION R323 STORM SHELTERS**

Revise as follows:

**R323.1 General.** This section applies to storm shelters where constructed as separate detached buildings or where constructed as safe rooms within buildings for the purpose of providing refuge from storms that produce high winds, such as tornados and hurricanes. In addition to other applicable requirements in this code, storm shelters shall be constructed in accordance with ICC_NSSA-500.

Add new text as follows:

**R323.1.1 Sealed documentation.** The construction documents for all structural components and impact-protective systems of the storm shelter shall be prepared and sealed by a registered design professional indicating that the design meets the criteria of ICC-500.

**Exception:** Storm shelters, structural components and impact-protective systems that are listed and labeled to indicate compliance with ICC-500.

**Reason:** This proposal is submitted by the National Storm Shelter Association (NSSA) and the ICC 500 Storm Shelter Standard Development committee. The ICC 500 Standards Development committee is responsible for the development of the ICC/NSSA Standard for the Design and Construction of Storm Shelters. The committee is currently working on the development of the 2020 edition. In 2017 the ICC 500 committee held 7 open conference calls. In addition, there were numerous Working Group meetings and conference calls, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/standards-development/is-stm.

NSSA was responsible for the development of the original standard for storm shelters in 2001, which ICC 500 replaced through an agreement between ICC and NSSA. Representing General, User and Producer interest categories, NSSA is a technical organization that is committed to promoting consistent quality in both residential and community storm shelters.
The term “storm shelter” is used throughout ICC-500 and is defined in the IBC but is not defined in the IRC. The definition proposed in this code change matches the definition in the IBC.

This proposed modification removes the words “as safe rooms” because that language is not necessary and is not defined.

The standard is ICC-500, not ICC/NSSA-500.

Currently, IRC R323.1 requires designs of storm shelters comply with ICC/NSSA-500. However, the National Storm Shelter Association (NSSA) has received reports of failures around the country and even a death in Mayflower, Arkansas associated with residential storm shelters that are not designed in accordance with ICC/NSSA-500. Impact-protective systems of non-engineered systems that builders call residential storm shelters have failed prematurely when they did not meet the testing requirements of ICC/NSSA-500. Additionally, non-engineered systems that builders call residential storm shelters have floated above ground (Figure 2) when they aren’t designed for the required load and resistance factors defined by ASCE 7, which is referenced by ICC/NSSA-500. It is important to note that the NSSA indicates that none of these failures have occurred in residential shelters manufactured by NSSA producer members, which have their shelters engineered before NSSA will provide them with a seal for their residential storm shelter. The provisions of ICC/NSSA-500 cannot be met by any prescriptive methods in the IRC and therefore require the expertise of a registered design professional.
Figure 1: Photograph of the residential shelter after a tornado caused a death in Mayflower, Arkansas
As an example of where the IRC has a similar requirement that a registered design professional provide documentation indicating compliance with a standard in a similar circumstance: The current language in the IRC requires that “the construction documents shall include documentation that is prepared and sealed by a registered design professional” indicating that the design complies with certain criteria in R322.3.9 for coastal high-hazard areas.

The proposed exception allows building officials to waive the requirement for a design professional to provide documentation indicating compliance with the design requirements of ICC/NSSA-500 where an approved agency has listed a product such as an entire storm shelter (e.g. an underground shelter with stated conditions for where it can be used) or portions of a storm shelter (e.g. a prefabricated shelter that is to be bolted onto a garage floor with a foundation to be designed by a design professional).

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This does not change construction requirements.

Proposal # 4846

RB146-19
**2018 International Residential Code**

Revise as follows:

**R324.3 Photovoltaic systems.** Photovoltaic systems shall be designed and installed in accordance with Sections R324.3.1 through R324.7.1, NFPA 70 and the manufacturer’s installation instructions. The electrical portion of solar PV systems shall be designed and installed in accordance with NFPA 70.

**R324.6 Roof access and pathways.** Roof access, pathways and setback requirements shall be provided in accordance with Sections R324.6.1 through R324.6.2.1. Access and minimum spacing shall be required to provide emergency access to the roof, to provide pathways to specific areas of the roof, provide for smoke ventilation opportunity areas, and to provide emergency egress from the roof.

**Exceptions:**

1. Detached, nonhabitable structures, including but not limited to detached garages, parking shade structures, carports, solar trellises and similar structures, shall not be required to provide roof access.
2. Roof access, pathways and setbacks need not be provided where the code official has determined that rooftop operations will not be employed.
3. These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (17-percent slope) or less.
4. Building integrated photovoltaic (BIPV) systems listed in accordance with Section 690.12(B)(2) of NFPA 70, where the removal or cutting away of portions of the BIPV system during firefighting operations have been determined to not expose a firefighter to electrical shock hazards.

**Reason:** This proposal correlates sections of the IRC with proposals that were approved by the IFC Committee for the 2021 International Fire Code under Group A.

The change to Section R324.3 is editorial only, and correlates the reference to NFPA 70 with the language from IFC Section 1204.1.

New Exception 4 in IRC Section R324.6 is based on new Exception 3 for 2021 IFC Section 1204.2, as created under Proposal F197-18 approved unanimously by the IFC Committee in Group A.

The technology of solar roofs has been advancing with new materials and methods, particularly in the area of BIPV. Unlike conventional PV panel systems mounted above the roof surface, BIPV systems are integrated into the finished roof surface, and do not present significant trip hazards or physical obstacles to equipment such as ladders that typically exist with other systems. Portions of these systems, and soon the entire roof system, may be listed to meet the NEC safety thresholds for firefighters upon rapid shutdown activation. There are BIPV systems available today that have been shown through testing to not present electrical hazards to firefighters even when cutting into them during ventilation operations. In order to build confidence in the safety features and performance of these systems an evaluation by a NRTL should be required.
These systems eliminate the hazard to firefighters for large portions of the roof, or in some cases the entire roof where BIPV is installed, eliminating the need to provide for access and pathways.

This proposal is intended to provide recognition of those safety levels by adding exceptions to the access and pathways portion of the IFC PV requirements.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This proposal correlates with Group A language changes and will not increase or decrease cost of construction.
2018 International Residential Code

Revise as follows:

**R324.3.1 Equipment listings.** Photovoltaic panels and modules shall be listed and labeled in accordance with UL 1703. Inverters shall be *listed* and *labeled* in accordance with UL 1741. Systems connected to the utility grid shall use inverters *listed* for utility interaction. *Mounting systems listed and labeled* in accordance with UL 2703 shall be installed in accordance with the manufacturer’s installation instructions and their listings.

**Reason:** This proposal provides direction on the use of mounting systems listed and labeled in accordance with UL 2703. These specially designed systems provide an alternative method for mounting.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There are numerous listed mounting systems available, and provides an alternative method for mounting the PV panels.
2018 International Residential Code

Revise as follows:

R324.5 Building-integrated photovoltaic systems. Building-integrated photovoltaic (BIPV) systems that serve as roof coverings shall be designed and installed in accordance with Section R905.

R324.5.1 Photovoltaic shingles. Photovoltaic shingles shall comply with Section R905.16.

R324.5.2 Fire classification. Building-integrated photovoltaic systems shall have a fire classification in accordance with Section R902.3.

Add new text as follows:

R324.5.3 BIPV roof panels. BIPV roof panels shall comply with Section R905.17.

Reason: Section R905.17 was added to the IRC in the last code cycle for BIPV roof panels, but a specific pointer to that section was not included in Section R324. This proposal provides that pointer and this is similar to what is being done for photovoltaic shingles in Section 324.5.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no cost impact as this is only adding a specific pointer to a section within the code.
2018 International Residential Code

Add new text as follows:

**R324.5.3 Markings at BIPV roof coverings.** Where Building Integrated Photovoltaic (BIPV) roof coverings are installed in a manner that creates areas with electrical hazards to be hidden from view, markings shall be provided to identify the hazardous areas to avoid. The markings shall be reflective and shall be visible from grade.

**Exception:** BIPV systems listed in accordance with Section 690.12(B)(2) of NFPA 70, where the removal or cutting away of portions of the BIPV system during firefighting operations have been determined to not expose a firefighter to electrical shock hazards.

**Reason:** This proposal intends to correlate provisions in the IRC with the successful proposal F200-18 in the IFC.

When Building Integrated Photovoltaic (BIPV) Systems are installed as the roof covering, the areas containing electrical hazards can be hidden from view of firefighters and other responders seeking to access the roof for emergency operations. With at least one manufacturer the entire roof surface has the same appearance—photovoltaic and non-photovoltaic tiles have the same finish, preventing any awareness of where the system is located.

The purpose of this proposal is to require markings warning firefighters and others that access the roof of where the areas are they must avoid for safety purposes. The marking must be readily visible day and night and visible from grade to avoid ground ladder placement at an area with an electrical hazard.

The exception for this requirement is consistent with the language approved by the IFC Committee in proposal F200-18.

**Cost Impact:** The code change proposal will increase the cost of construction

The increase of cost of construction is specific to BIPV systems and only includes additional marking or labeling.
RB151-19
IRC®: R324.6.2.2

Proponent: Joseph H. Cain, Solar Energy Industries Association (SEIA), representing Solar Energy Industries Association (SEIA) (JoeCainPE@gmail.com); Kevin Reinertson, Riverside County Fire Department, representing California Fire Chiefs Association (kevin.reinertson@fire.ca.gov)

2018 International Residential Code
Revise as follows:

R324.6.2.2 R324.6.3 Emergency escape and rescue openings. Panels and modules installed on dwellings shall not be placed on the portion of a roof that is below an emergency escape and rescue opening. A pathway not less than 36 inches (914 mm) wide shall be provided to the emergency escape and rescue opening.

Exception: BIPV systems listed in accordance with Section 690.12(B)(2) of NFPA 70, where the removal or cutting away of portions of the BIPV system during firefighting operations have been determined to not expose a firefighter to electrical shock hazards.

Reason: The technology of solar roofs has been advancing with new materials and methods, particularly in the area of BIPV. Unlike conventional PV panel systems mounted above the roof surface, BIPV systems are integrated into the finished roof surface, and do not present significant trip hazards or physical obstacles to equipment such as ladders that typically exist with other systems. Portions of these systems, and soon the entire roof system, may be listed to meet the NEC safety thresholds for firefighters upon rapid shutdown activation. There are BIPV systems available today that have been shown through testing to not present electrical hazards to firefighters even when cutting into them during ventilation operations. In order to build confidence in the safety features and performance of these systems an evaluation by a NRTL should be required. These systems eliminate the hazard to firefighters for large portions of the roof, or in some cases the entire roof where BIPV is installed, eliminating the need to provide for access and pathways.

This proposal is intended to provide recognition of those safety levels by adding exceptions to the access and pathways portion of the IFC PV requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal only provides a BIPV exception to access pathways to emergency escape & rescue openings, and will not increase or decrease the cost of construction.

Proposal # 5088
2018 International Residential Code

Revise as follows:

R325.6 Habitable attic. A habitable attic shall not be considered to be a story above grade plane, a story where complying with all of the following requirements:

1. The occupiable floor area is not less than 70 square feet (17 m²), in accordance with Section R304.
2. The occupiable floor area has a ceiling height in accordance with Section R305.
3. The occupiable space is enclosed by the roof assembly above, knee walls (if applicable) on the sides and the floor-ceiling assembly below.
4. The floor of the occupiable space shall not extend beyond the exterior walls of the floor below.

Reason: The topic of habitable attics in the International Residential Code was discussed at length in previous hearings. During our code development process in New York State (which is based on the I-Codes), we have realized that allowing a habitable level above the third story above grade plane that is not considered a “story”, creates both an inconsistency between the IRC and the IBC and a potential threat to the life and safety of occupants living in dwellings regulated under this code. This same change has been proposed to the New York State Uniform Building Code Council for consideration.

1. The current allowance for a “habitable attic” in the IRC creates an inconsistency within the I-Codes.

In its introduction, the IRC states the IRC is “fully compatible with all the International Codes® (I-Codes®) published by the International Code Council® (ICC®), including the International Building Code® (IBC®).” The IRC also states in the section entitled “Effective Use of the International Residential Code” the following:

“All buildings within the scope of the IRC are limited to three stories above grade plane. For example, a four-story single-family house would fall within the scope of the International Building Code® (IBC®), not the IRC.”

Traditionally, the scope of the Residential Code has been limited to three-stories. The IRC currently allows additional habitable spaces within one- and two-family dwellings and townhouses that enlarge the size of a dwelling while still considering it a “three-story”: a habitable attic and story below grade plane (a basement). With a habitable attic not considered a story, a dwelling can now have 5 habitable levels, which we believe conflicts with the scope and intent of the Residential Code. It should be noted that there is no limit to the area of a habitable attic. The occupiable floor area and ceiling height requirements in Items 1 and 2 of Section R325.6 are just minimums required for habitable space. For example, a modest footprint three story dwelling with a cape cod style roof, could easily accommodate two bedrooms and a bathroom on the fourth habitable level above grade plane. A larger estate size dwelling could have as much space on that fourth habitable attic level as a small ranch style house.

As justification for this position, consider that the 2015 International Building Code® Illustrated Handbooks contains the following definition of an attic:

**ATTIC.** Several provisions apply to the attic area of a building, such as those relating to ventilation of the attic space. In order to fully clarify that portion of a building defined as an attic, Chapter 2 identifies an attic as that space between the ceiling beams at the top story and the roof rafters. An attic designation is appropriate only if
the area is not considered occupiable. Where this area has a floor, it would be defined as a story. A common misuse of IBC terminology is the designation of a space as a habitable or occupiable attic. Such a designation is inappropriate insofar as once such a space is utilized for some degree of occupancy; it is no longer deemed an attic.

While this handbook is not enforceable, it acts as a commentary on the IBC and provides guidance as to how the IBC views individual provisions and definitions. As stated above, the IBC considers a space an attic when it “is not considered occupiable”. When a space becomes “habitable or occupiable” it is considered a story in the IBC. Hence, a three story one-family dwelling with a habitable attic would be considered a four-story building in the IBC.

There appears to be a conflict between how the IBC and the IRC views the same space. This conflict is allowing the creation of a space under the IRC which would require additional safety measures if built under the IBC. The IBC currently does not have a definition for a “habitable attic” nor any provisions that would allow this space to not be considered a story. Historically, the I-Codes have treated an attic that is habitable as a story.

2. Allowing the creation of a habitable attic, but not considering it an additional story, is allowing a structure that potentially creates unmitigated life-safety hazards.

The IRC currently restricts one- and two-family dwellings and townhouses to be three-stories above grade plane with an unlimited area. For comparison purposes, this is consistent with the R-3 occupancy classification of the IBC. The Tables 504.3 and 504.4 of the 2018 IBC limit the building heights on R-3 occupancies to 40 feet or three stories for buildings equipped with a NFPA 13D automatic sprinkler system and 60 feet or four-stories for buildings equipped with a NFPA 13R automatic sprinkler system, respectively. It is noted that these tables were updated in the 2018 version of the IBC by a Code Action Committee of the ICC to address the consistency of the IBC (Refer to Code Change Proposal G133-15).

For a three-story, one-family dwelling with habitable space in the attic, the maximum story height is limited to 11'-7" in both the IRC and the IBC. Using both a typical story height (8'-0" ceiling height with a 1'-0" structural space) and the maximum story height, the following figures illustrate some possible building heights that can be achieved. Along with this comparison, Table 1 highlights some life-safety features that would result when these structures are constructed under either the IRC or the IBC. It should also be noted that the code currently does not bring into consideration habitable attics that include dormers or various roof styles (such as a mansard roof) that could easily blur the lines of the current definitions and create spaces that appear to miss the intentions of the original code change proposal.

<th>IBC Requirements</th>
<th>Occupancy Group R-3</th>
</tr>
</thead>
<tbody>
<tr>
<td>• 2018 IRC considers this a 3-Story Dwelling with a Habitable Attic</td>
<td></td>
<td>• 4-story Dwelling</td>
<td></td>
</tr>
<tr>
<td>• 2018 IRC Section R313.2 requires a Section P2904 or NFPA 13D sprinkler system, which results in a 10-minute sprinkler duration (P2904.5.2)</td>
<td></td>
<td>• IBC Table 504.4 would require a NFPA 13R sprinkler system, with a minimum 30-minute sprinkler duration for 4-stories (NFPA 13R Section 9.2)</td>
<td></td>
</tr>
<tr>
<td>• EERO required in the Habitable Attic (R310.1)</td>
<td></td>
<td>o Alternative: Type IV or higher rated construction with</td>
<td></td>
</tr>
</tbody>
</table>
• 35’ ladder reaches 3rd story EERO, but may fail to reach the Habitable Attic (4th Level) EERO in Fig. 1, and fails to reach the Habitable Attic (4th Level) EERO in Fig. 2

an NFPA 13D system

• EERO not required above the 3rd story due to their ineffectiveness at that height (IBC Section 1030.1)
• 35’ ladder reaches 3rd story EERO, but may fail to reach the Habitable Attic (4th Level) EERO in Fig. 1, and fails to reach the Habitable Attic (4th Level) EERO in Fig. 2

As is shown in Table 1, the result of applying either the IRC or the IBC would result in different safety levels for the same structure.

Figure 3: Walkout basement (not considered a story above grade plane) with typical story height, floor-to-floor, of 9'-0'
To correct this inconsistency, we recommend altering the IRC to consider a habitable attic a story above grade plane, as has been the historical interpretation of the IRC, and is the current practice of the IBC. The change would require new dwellings that exceed the three-story limit permitted under the IRC to be constructed to meet the structural and life-safety standards of the IBC. This will increase the safety of these tall dwellings and bring greater consistency across the I-Codes. We also recommend deleting the qualifying Items 1 through 4 because, once the habitable attic level is considered a story above grade plane, the qualifiers are not necessary.

We recommend the definition of, “Attic, Habitable” should remain unchanged because it differentiates that area of a building which contains “habitable space” from a typical “attic” as defined. The definition stating that a habitable attic can be finished or unfinished takes away the arguments made by those who would seek to disqualify the area in question because it is unfinished in some way. If the area is being used as habitable
space, all other requirements necessary for a space to be considered habitable must be provided.

On the other hand, if the area is being used for non-habitable space such as for equipment or storage, then the owner should not be required to provide EEROs, egress stairs and other items required for habitable space, just because it has the minimum area and ceiling height requirements of a habitable space. Code enforcement officers could condition the Certificate of Occupancy for such a dwelling as a three-story structure with attic storage not approved for use as habitable space.

**Cost Impact:** The code change proposal will increase the cost of construction
This code change, by returning to the historical interpretation and application of the IRC, would increase the cost of construction only when a habitable attic is above a third story, creating a fourth-story above grade plane. This change would potentially force some dwellings to be constructed under the IBC rather than the IRC, which would trigger height limitations and the need for higher types of construction and additional life-safety measures, including the potential to install a NFPA 13R system rather than a NFPA 13D system. This cost increase reflects the need to offset the increased risk of these structures.

2018 International Residential Code

SECTION R202
DEFINITIONS

Delete without substitution:

[B] BATTERY SYSTEM, STATIONARY STORAGE. A rechargeable energy storage system consisting of electrochemical storage batteries, battery chargers, controls and associated electrical equipment designed to provide electrical power to a building. The system is typically used to provide standby or emergency power, an uninterruptable power supply, load shedding, load sharing or similar capabilities.

Add new definition as follows:

[B] Energy Storage Systems (ESS). One or more devices, assembled together, capable of storing energy in order to supply electrical energy at a future time.

Revise as follows:

SECTION R327
STATIONARY-ENERGY STORAGE BATTERY-SYSTEMS

R327.1 General. Stationary storage battery systems ESS shall comply with the provisions of this section.

R327.2 Equipment listings. Stationary storage battery systems ESS shall be listed and labeled for residential use in accordance with UL 9540.

Exceptions:

1. Where approved, repurposed unlisted battery systems from electric vehicles are allowed to be installed outdoors or in detached sheds located not less than 5 feet (1524 mm) from exterior walls, property lines and public ways.
2. Battery systems that are an integral part of an electric vehicle are allowed provided that the installation complies with Section 625.48 of NFPA 70.
3. Battery systems less than 1 kWh (3.6 megajoules).

R327.3 Installation. Stationary storage battery systems ESS shall be installed in accordance with the manufacturer's instructions and their listing, if applicable, and shall not be installed within the habitable space of a dwelling unit.

R327.4 Electrical installation. Stationary storage battery systems ESS shall be installed in accordance with
NFPA 70. Inverters shall be *listed* and *labeled* in accordance with UL 1741 or provided as part of the UL 9540 listing. Systems connected to the utility grid shall use inverters listed for utility interaction.

**R327.5 Ventilation.** Indoor installations of *stationary storage battery systems (ESS)* that include batteries that produce hydrogen or other flammable gases during charging shall be provided with ventilation in accordance with Section M1307.4.

Add new text as follows:

**R327.6 Commissioning.** ESS shall be commissioned as follows:

1. Verify that the system is installed in accordance with the approved plans and manufacturer’s instructions and is operating properly.
2. Provide a copy of the manufacturer’s installation, operation, maintenance, and decommissioning instructions provided with the listed system.
3. Provide training on the proper operation and maintenance of the system to the system owner.
4. Provide a label on the installed system containing the contact information for the qualified maintenance and service providers.

**R327.6.1 Installation prior to closing.** Where the system is installed in a one- or two-family dwelling or townhouse that is owned by the builder and has yet to be sold, commissioning shall be conducted as outlined in Section R327.6, and the builder shall then transfer the required information in Section R327.6 to the home owner when the property is transferred to the owner at the closing.

Revise as follows:

**R327.6 R327.7 Protection from impact.** *Stationary storage battery systems (ESS)* installed in a location subject to vehicle damage shall be protected by approved barriers.

**Reason:** The purpose of this proposal is two fold. First it replaces the term Stationary Battery Storage System with Energy Storage Systems (ESS) throughout the document. The existing term is from older editions of the IFC and legacy codes and based on older concepts. The new term suggested is the industry recognized term and is what both the IFC and NFPA 855 Energy Storage Systems use to identify these systems. The second item is the addition of R327.6 for commissioning requirements as part of the installation of ESS. These systems are new technology and intricate. Commissioning is necessary to ensure a proper installation and proper operation of the systems once installed. This requirement is consistent with requirements added to the IFC for R-3 and R-4 Group occupancies and NFPA 855 requirements for one- and two-family homes and townhouses.

Usually these systems are added to an existing dwelling by the current owner. In the rare case a system is installed as part of construction of a custom home, new Section R327.6.1 provides for the nadoff of the commissioning paperwork to the new owner after closing. This is consistent with what is done for the manufacturer’s paperwork for other appliances and for fire alarms systems.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposed change does not impact the cost of construction of one- or two-family dwellings and townhouses. ESS are specialty systems typically installed in an existing dwelling by the current owner. In the rare case that a new custom home owner desires installation of ESS as part of the construction of the custom home, these requirements impact the cost of the ESS portion of the installation not the home itself. These requirements will increase the cost of installation of ESS.

Proponent: Robert Davidson, Davidson Code Concepts, LLC, representing Tesla, USA (rjd@davidsononcodeconcepts.com); Kevin Reinertson, representing Riverside County Fire Department (kevin.reinertson@fire.ca.gov); Jack Applegate, representing City of Clatskanie, Oregon (jacka@nwcodepros.com)

2018 International Residential Code

SECTION R202
DEFINITIONS

Delete without substitution:

[RB] BATTERY SYSTEM, STATIONARY STORAGE. A rechargeable energy storage system consisting of electrochemical storage batteries, battery chargers, controls and associated electrical equipment designed to provide electrical power to a building. The system is typically used to provide standby or emergency power, an uninterruptable power supply, load shedding, load sharing or similar capabilities.

Add new definition as follows:

[RB] ENERGY STORAGE SYSTEM (ESS). One or more devices, assembled together, capable of storing energy in order to supply electrical energy at a future time.

Revise as follows:

SECTION R327
STATIONARY-ENERGY STORAGE BATTERY SYSTEMS

R327.1 General. Stationary storage battery system shall comply with the provisions of this section. ESS shall be installed and maintained in accordance with Sections R327.2 through R327.4. The temporary use of an owner or occupant's electric powered vehicle as an ESS shall be in accordance with Section R327.5.

R327.2 Equipment listings. Stationary storage battery systems ESS 1 kWh or greater in maximum stored energy shall be listed and labeled for residential use in accordance with UL 9540.

Exceptions:

1. Where approved, repurposed unlistered battery systems from electric vehicles are allowed to be installed outdoors or in detached sheds located not less than 5 feet (1524 mm) from exterior walls, property lines and public ways.

2. Battery systems that are an integral part of an electric vehicle are allowed provided that the installation complies with Section 625.48 of NFPA 70. ESS listed and labeled in accordance with UL 9540 solely for utility or commercial use installed in accordance with Section 1206 of the International Fire Code.

3. Battery systems less than 1 kWh (3.6 megajoules).

R327.3 Installation. Stationary storage battery systems ESS shall be installed in accordance with the
manufacturer’s instructions and their listing, if applicable, and shall not be installed within the living space or habitable space of a dwelling unit.

Add new text as follows:

**R327.3.1 Spacing.** Individual units shall be separated from each other by at least three feet of spacing unless smaller separation distances are documented to be adequate as approved by the code official based on large scale fire testing complying with Section 1206.1.5 of the International Fire Code.

**327.3.2 Location.** ESS shall only be installed in the locations listed in items 1 through 4.

1. Detached garages and detached accessory structures.
2. Attached garages separated from the dwelling unit living space and sleeping units in accordance with Section R302.6.
3. Outdoors on exterior walls or on the ground located a minimum 3 ft. from doors and windows.
4. Enclosed utility closets or spaces, or enclosed storage closets within dwelling units.

**R327.3.3 Energy ratings.** Individual ESS units shall have a maximum stored energy of 20 kWh. The aggregate rating within or outside the structure shall not exceed:

1. 40 kWh within utility closets and storage or utility spaces.
2. 80 kWh in attached or detached garages and detached accessory structures.
3. 80 kWh on exterior walls.
4. 80 kWh outdoors on the ground.

ESS installations exceeding the permitted individual or aggregate ratings shall be installed in accordance with Section 1206 of the International Fire Code.

Revise as follows:

**R327.4 R327.3.4 Electrical installation.** Stationary storage battery systems ESS shall be installed in accordance with NFPA 70. Inverters shall be listed and labeled in accordance with UL 1741 or provided as part of the UL 9540 listing. Systems connected to the utility grid shall use inverters listed for utility interaction.

**R327.5 R327.3.5 Ventilation.** Indoor installations of stationary storage battery systems ESS that include batteries that produce hydrogen or other flammable gases during charging normal operation shall be provided with ventilation in accordance with Section M1307.4. M1307.4.2.

**R327.6 R327.3.6 Protection from impact.** Stationary storage battery systems ESS installed in a location subject to vehicle damage shall be protected by approved barriers.

Add new text as follows:

**R327.3.7 Fire separation** When located within a garage, utility closet or space, or storage closet, the garage, room or space shall be separated as required by Table R327.3.7. Attachment of gypsum board shall comply with Table R702.3.5. The wall separation provisions of Table R327.3.7 shall not apply to garage walls that are perpendicular to the adjacent dwelling unit wall.

<table>
<thead>
<tr>
<th>SEPARATION</th>
<th>MATERIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the residence and attics</td>
<td>Not less than 1/2-inch gypsum board or equivalent applied to the garage, room or space side</td>
</tr>
</tbody>
</table>
From habitable rooms above the garage, room or space | Not less than 5/8-inch Type X gypsum board or equivalent
---|---
Structure(s) supporting floor/ceiling assemblies used for separation required by this section | Not less than 1/2-inch gypsum board or equivalent
Garages located less than 3 feet from a dwelling unit on the same lot | Not less than 1/2-inch gypsum board or equivalent applied to the interior side of exterior walls that are within this area

R327.3.7.1 **Openings.** Openings from a garage, room or space directly into a room used for sleeping purposes shall be prohibited.

R327.3.7.2 **Penetrations.** Penetration protection shall be provided at openings in walls, ceilings and floors around vents, pipes, ducts, cables and wires, with an approved material to resist the free passage of flame and products of combustion. The material filling this annular space shall not be required to meet the ASTM E136 requirements.

R327.3.8 **Fire detection.** Interconnected smoke alarms shall be installed throughout the dwelling in accordance with Section R314, including in the room or area within the dwelling or attached garage in which the ESS are installed. A heat detector listed and interconnected to the smoke alarms shall be installed in the room or area within the dwelling or attached garage in which the ESS is installed where smoke alarms cannot be installed based on their listing.

R327.4 **Toxic and highly toxic gas.** ESS that have the potential to release toxic or highly toxic gas during charging, discharging and normal use conditions shall be installed outdoors.

R327.5 **Electric vehicle use.** The temporary use of an owner or occupant’s electric powered vehicle to power a dwelling unit while parked in an attached or detached garage or outside shall comply with the vehicle manufacturer’s instructions and NFPA 70. The batteries on electric vehicles shall not contribute to the aggregate energy limitations in Section R327.4.3.

R327.5.1 **Temporary.** The temporary use of the dwelling unit owner’s or occupant’s electric-powered vehicle to power the dwelling while parked in an attached or detached garage or outside shall not exceed 30 days.

**Reason:** Last cycle the portion of the International Fire Code dealing with Stationary Battery Storage Systems was heavily rewritten by the Energy Storage Work Group of the ICC Fire Code Action Committee to address changes in technology and application of battery storage systems. When that work was accepted by the IFC Committee and the voting membership, new Section R327 was added to the International Residential Code to provide for some core requirements when the systems are installed in one- and two-family dwellings and townhouses.

Simultaneous to that work, NFPA created a new NFPA 855 Energy Storage Systems Standard for a comprehensive document addressing the hazards of energy storage systems. The ICC FCAC Energy Storage Work Group continued to work on the topic in coordination with the work being done by the NFPA 855 committee to keep the technical details of the documents as coordinated as possible. As a result, the new requirements in the 2018 edition of the IFC have been heavily updated as to structure and the topics covered.

This proposal is an outgrowth of work done by the NFPA 855 Committee specific to one- and two-family dwellings and townhouses as well as new language added to the IFC for the 2021 edition addressing R-3 and R-4 Group Occupancies.

The concerns identified for one and two-family dwellings and townhouses dealt with:

- Where the ESS units could be located.
• Energy rating maximum of individual units.
• Aggregate energy ratings when more than one unit is installed.
• Linkage to the fire code when energy limitations are exceeded.
• Fire separation.
• Fire detection.
• ESS that may produce toxic or highly toxic gases during operation.
• Temporary use of electric vehicle as ESS for the dwelling.

The breakdown of the suggested changes are as follows:

**New definition:** The definition for Energy Storage Systems (ESS) from the IFC has been brought over to the IRC for consistency of terminology between the IFC and NFPA 855.

**R327 generally:** The term Energy Storage Systems has replaced the term Stationary Storage Battery Systems.

**R327.1:** Has been modified to identify the sections ESS shall comply with and to add a separate pointer for the section applicable to the temporary use of an electric vehicle as an ESS.

**R327.2:** Has been modified to pull the exception for the systems with less than 1 kWh and provide it as the energy rating level trigger for cleaner application of the requirements. Exception 2 has been deleted since the use of electric vehicles is covered by the new section R327.5. In its place language has been added providing for the installation of utility or commercial listed systems (not listed for residential use) to be outside the dwelling and to be in accordance with the IFC. Exception 3 is deleted since that topic is now covered by the initial language at the start of R327.2.

**R327.3:** Has been modified to replace the current terminology with ESS, and a restriction against installation in “living space” has been added to address concerns that there are other locations such as hallways that are not covered by the existing restriction for habitable spaces. That addition provides consistency with language added to NFPA 855.

**New R327.3.1:** Adds a separation requirement of 3 feet between ESS units unless large scale testing has documented that an event in one unit will not propagate to the next unit.

**New R327.3.2:** Adds a listing of specific installation locations consistent with the IFC R-3 and R-4 locations and NFPA 855.

**New R327.3.3:** Provides a limitation on the maximum energy rating of an individual unit as well as an aggregate energy rating for specific installation locations. The size of an event is directly correlated to the amount of energy stored. It then provides that if increased energy above these limits is desired the installation shall be done in accordance with the IFC.

**R327.3.4 (Prior R327.4):** Has been modified to replace the current terminology with ESS.

**R327.3.5 (Prior R327.5):** Has been modified to replace the current terminology with ESS. The term “charging” has been replaced with the phrase “normal operation”. It doesn’t matter at what point the gases are produced, they need to be exhausted. Section M1307.4 was changed to Section 1307.4.2 to clarify this is a mechanical exhaust system that is required.

**R327.3.6 (Prior R327.6):** Has been modified to replace the current terminology with ESS.
New R327.3.7: This section has been added to address the need for fire separation. When an event occurs, it cannot always be extinguished with water. Exposures would be wetted while the unit burns itself out. For that reason, separation is needed to assist in preventing fire spread. The language from existing Section 302.6 was taken for consistency and editorially modified slightly to fit this area of the code.

New R327.3.7.1: Adds the first sentence of existing Section R302.5.1 to keep rooms or spaces with ESS from opening into areas for sleeping purposes. (The remainder of R302.5.1 concerning doors and closures is part of a separate proposal).

New R327.3.7.2: Adds language from existing Section R302.11, Item 4, (as referenced by existing R302.5.3), with editorial changes to fit this application.

New R327.3.8: Adds a requirement that when ESS is installed the dwelling must have an interconnected smoke alarm system with a smoke alarm installed in the room or space the ESS is located for early warning of an event. If the space is not conducive to the installation of a smoke alarm a listed heat alarm can be installed and interconnected to the smoke alarm system.

New R327.4: Provides that an ESS that has the potential to release toxic or highly toxic gases during normal use shall be installed outdoors.

New R327.5: Provides for the temporary use of an electric vehicle as an ESS to power the dwelling provide it is done in compliance with the NEC and the manufacturer’s instructions. The requirement for the manufacturer’s instruction compliance ensures that only electric vehicles designed and manufactured for use as an ESS are utilized as compared to someone adding non-approved electrical connections to an existing electric vehicle not designed for this purpose. Temporary is further defined as 30 days with new Section R327.5.1.

These changes will provide for correlation with the new language added to the IFC as well as enhancements made when the language was added to NFPA 855. This correlation provides for consistency or requirements across codes and standards.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposed change does not impact the cost of construction of one- or two-family dwellings and townhouses. ESS are specialty systems typically installed in an existing dwelling by the current owner. In the rare case that a new custom home owner desires installation of ESS as part of the construction of the custom home, these requirements impact the cost of the ESS portion of the installation not the home itself. The separation requirements were intentionally matched to the existing private garage separation requirements for correlation with construction of the home. These requirements will increase the cost of installation of ESS.
Add new definition as follows:

**ENERGY STORAGE SYSTEM (ESS).** One or more devices that are assembled together and capable of storing electric energy for future use.

Revise as follows:

**SECTION R327**

**STATIONARY ENERGY STORAGE BATTERY SYSTEMS**

R327.1 General. Stationary Energy storage battery systems shall comply with the provisions of this section.

R327.2 Equipment listings. Stationary Energy storage battery systems shall be listed and labeled for residential use in accordance with UL 9540.

**Exceptions:**

1. Where approved, repurposed unlisted battery systems from electric vehicles are allowed to be installed outdoors or in detached sheds located not less than 5 feet (1524 mm) from exterior walls, property lines and public ways.
2. Battery systems that are an integral part of an electric vehicle are allowed provided that the installation complies with Section 625.48 of NFPA 70.
3. Battery systems less than 1 kWh (3.6 megajoules).

R327.3 Installation. Stationary Energy storage battery systems shall be installed in accordance with the manufacturer’s instructions and their listing, if applicable, and shall not be installed within the habitable space of a dwelling unit.

Add new text as follows:

**R327.3.1 Opening protection.** Openings from a garage or energy storage system room or space directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage, or between a room or space containing an energy storage system and the living space or habitable space of a dwelling unit shall be equipped with solid wood doors not less than 1 3/8 inches (35 mm) in thickness, solid or honeycomb core steel doors not less than 1 3/8 inches (35 mm) thick, or 20-minute fire-rated doors. Such doors shall be equipped with a self-closing or automatic-closing device.

Revise as follows:
R327.4 R327.3.2 Electrical installation. Stationary-Energy storage battery systems shall be installed in accordance with NFPA 70-Chapters 34 through 43. Inverters shall be listed and labeled in accordance with UL 1741 or provided as part of the UL 9540 listing. Systems connected to the utility grid shall use inverters listed for utility interaction.

R327.5 R327.3.3 Ventilation. Indoor installations of stationary-energy storage battery systems that include batteries that produce hydrogen or other flammable gases during charging shall be provided with ventilation in accordance with Section M1307.4. M1307.4.2.

R327.6 R327.3.4 Protection from impact. Stationary-Energy storage battery systems installed in a location subject to vehicle damage shall be protected by approved barriers.

R327.3 Installation. Stationary storage battery systems shall be installed in accordance with the manufacturer’s instructions and their listing, if applicable, and shall not be installed within the habitable space of a dwelling unit.

Reason: This proposal addresses three items.
1 - The proposal brings over the definition of Energy Storage Systems from the International Fire Code and the term Stationary Battery Storage Systems has been modified to instead use the Energy Storage Systems term. This will provide consistency with the fire code and the current industry terminology for such systems.

2 - A new section R327.3.1 on openings is added. The proposed language restricts openings from spaces where ESS are installed to protect the dwelling and occupants if a thermal runaway event occurs and applies the same requirements for door type and closure that is utilized for attached private garages. The language was obtained from existing section R302.5.1 with minor editorial modification to fit this new location.

R302.5.1 Opening protection.

Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence shall be equipped with solid wood doors not less than 13/8 inches (35 mm) in thickness, solid or honeycombcore steel doors not less than 13/8 inches (35 mm) thick, or 20-minute fire-rated doors, equipped with a self-closing or automatic-closing device.

3 - The section numberings have been modified clarifying that existing Sections R327.4 thru R327.6 are installation requirement subsections.

Cost Impact: The code change proposal will increase the cost of construction
The additional requirement of a door or closure will minimally increase the overall cost of ESS installations.

Proposal # 4828

RB155-19
2018 International Residential Code

Revise as follows:

R327.3 Installation. Stationary storage battery systems shall be listed and installed in accordance with the manufacturer’s instructions and their listing, if applicable, and shall not be installed within the habitable space only in the following locations of a dwelling unit.

1. In attached garages separated from the dwelling unit living and sleeping spaces in accordance with Section R302.6.
2. In detached garages.
3. In detached accessory structures.
4. Outdoors on exterior walls and located at a distance of not less than 3 ft. from doors and windows.

Reason: This revision corrects a problem with the existing code that allows the installation of ESS units in closets and other storage spaces without any special precautions, which is unsafe. The definition of habitable space in the IRC (A space in a building for living, sleeping, eating or cooking. Bathrooms, toilet rooms, closets, halls, storage or utility spaces and similar areas are not considered habitable spaces.) specifically points out that closets and storage spaces are not habitable spaces. This revision also requires ESS units to be listed.

Cost Impact: The code change proposal will increase the cost of construction
This proposal may require special provisions for installation of ESS units.
2018 International Residential Code

Revised as follows:

R327.3 Installation. Stationary storage battery systems shall be installed in accordance with the manufacturer’s instructions and their listing, if applicable, and shall not be installed within the habitable space of a dwelling unit.

Add new text as follows:

R327.3.1 Locations. Stationary storage battery systems installed in a dwelling unit shall be listed and marked “For use in residential dwelling units.”

Exceptions:

1. Stationary storage battery systems installed in an attached garage, that is separated from the dwelling unit in accordance with Section R302.6.
2. Stationary storage battery systems installed in a detached garage or detached accessory structure.
3. Stationary storage battery systems installed in an enclosed utility room.

Reason: R327.2 already requires stationary battery storage systems covered by this code to be listed for residential use in accordance with UL 9540. This proposal clarifies that stationary battery storage systems installed within the dwelling unit itself shall comply with new UL 9540 listing requirements being developed and clarifies locations where the additional listing requirements do not apply.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This does not increase the cost of construction. It merely provides closer correlation with listing requirements.
2018 International Residential Code

Add new definition as follows:

**[RB] ENERGY STORAGE SYSTEM (ESS).** One or more devices, assembled together, that are capable of storing energy for supplying electrical energy at a future time.

Delete without substitution:

**[RB] BATTERY SYSTEM, STATIONARY STORAGE.** A rechargeable energy storage system consisting of electrochemical storage batteries, battery chargers, controls and associated electrical equipment designed to provide electrical power to a building. The system is typically used to provide standby or emergency power, an uninterruptable power supply, load shedding, load sharing or similar capabilities.

Revise as follows:

**SECTION R327**

**STATIONARY ENERGY STORAGE BATTERY SYSTEMS (ESS)**

**R327.1 General.** **Stationary storage battery system** Energy Storage Systems (ESS) shall comply with the provisions of this section.

**R327.2 Equipment listings.** **Stationary storage battery systems** ESS shall be listed and labeled for residential use in accordance with UL 9540.

**Exceptions:**

1. Where approved, repurposed unlisted battery systems from electric vehicles are allowed to be installed outdoors or in detached sheds located not less than 5 feet (1524 mm) from exterior walls, property lines and public ways.
2. Battery systems that are an integral part of an electric vehicle are allowed provided that the installation complies with Section 625.48 of NFPA 70.
3. Battery systems less than 1 kWh (3.6 megajoules).

**R327.3 Installation.** **Stationary storage battery systems** ESS shall be installed in accordance with the manufacturer’s instructions and their listing, if applicable, and shall not be installed within the habitable space of a dwelling unit.

**R327.4 Electrical installation.** **Stationary storage battery systems** ESS shall be installed in accordance with NFPA 70. Inverters shall be listed and labeled in accordance with UL 1741 or provided as part of the UL 9540 listing. Systems connected to the utility grid shall use inverters listed for utility interaction.

**R327.5 Ventilation.** Indoor installations of stationary storage battery systems that include batteries ESS that produce hydrogen or other flammable gases during charging shall be provided with ventilation in accordance with Section M1307.4.

**R327.6 Protection from impact.** **Stationary storage battery systems** ESS installed in a location subject to
vehicle damage shall be protected by approved barriers.

**Reason:** This proposal is strictly editorial and only changes the term “stationary storage battery systems” to “energy storage systems”. It also replaces the current definition of Stationary Storage Battery System with an Energy Storage System (ESS) definition approved for the 2021 IFC. Energy storage system is the common industry term and is used in the IFC and the IBC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is an editorial change only.

Proposal # 4833

RB158-19
2018 International Residential Code

Add new text as follows:

SECTION R328
STATIONARY ENGINE GENERATORS

R328.1 General. Stationary engine generators shall be listed and labeled in accordance with UL 2200 and shall comply with this section. The connection of stationary engine generators to the premise wiring system shall be by means of a listed transfer switch.

R328.2 Installation. The installation of stationary engine generators shall be in an approved location and in accordance with the listing, the manufacturer’s installation instructions, and Chapters 34 through 43.

Reason: Stationary generators are becoming a more common standby source of electrical power for one and two family dwellings. This proposal provides basic safety requirements for these installations, and the requirements are consistent with those included in Section 915 of the 2018 IMC and Section 616 of the 2018 IFGC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There are numerous stationary engine generators on the market that are listed to UL 2200, and they are typically installed in accordance with NFPA 70 and the manufacturer’s instructions.
2018 International Residential Code

SECTION R202
DEFINITIONS

Add new definition as follows:

[R] FUEL CELL POWER SYSTEM, STATIONARY. A stationary energy generation system that converts the chemical energy of a fuel and oxidant to electric energy (DC or AC electricity) by an electrochemical process.

Field-fabricated fuel cell power system. A stationary fuel cell power system that is assembled at the job site and is not a preengineered or prepackaged factory-assembled fuel cell power system.

Preengineered fuel cell power system. A stationary fuel cell power system consisting of components and modules that are produced in a factory, and shipped to the job site for assembly.

Prepackaged fuel cell power system. A stationary fuel cell power system that is factory assembled as a single, complete unit and shipped as a complete unit for installation at the job site.

Add new text as follows:

SECTION R328
STATIONARY FUEL CELL POWER SYSTEMS

R328.1 General. Stationary fuel cell power systems in new and existing buildings and structures shall comply with this section and Section 1205.1 of the International Fire Code.

Exception: The temporary use of a fuel cell powered electric vehicle to power a dwelling unit while parked shall comply with Section R328.3.

R328.2 Residential Listing. Stationary fuel cell power systems shall not be installed in dwelling units unless they are specifically listed for residential use.

R328.3 Fuel Cell Vehicle ESS Use. The temporary use of the dwelling unit owner’s or occupant’s fuel cell powered electric vehicle to power a dwelling while parked in an attached or detached garage or outdoors shall comply with the vehicle manufacturer’s instructions and NFPA 70.

R328.3.1 Temporary. The temporary use of the dwelling unit owner’s or occupant’s fuel cell powered electric vehicle to power the dwelling while parked in an attached or detached garage or outdoors shall not exceed 30 days.

Reason: This proposal builds on work done during last cycle with both the International Fire Code and this code relative to Energy Storage Systems (ESS) and work in the current cycle to update the IFC and this code. Last cycle the International Fire Code was updated with new requirements for ESS and a basic set of requirements.
were added to this code last cycle as well. This cycle the IFC requirements for ESS were updated and there is a companion proposal submitted to this code to update the IRC as well. Part of the work last cycle involved adding a new Section 1205 Stationary Fuel Cell Power Systems to the IFC with core requirements for the installation of fuel cell power systems. This cycle that section was updated to recognize the temporary use of fuel cell powered electric vehicles as ESS to power the dwelling unit on a temporary basis.

This proposal is intended to delete the existing limited language at M1903 and to provide needed guidance in this code for the installation of fuel cells that to correlate the updated language on ESS in the IRC with the IFC. It is important to note that these systems are designated by the USDOE as ESS, not simply mechanical systems. The same holds true for both the IFC and NFPA 855 Energy Storage Systems. Since these fuel cell power systems are utilized for ESS the code language pertaining to them should directly follow the requirements for ESS in the IRC as they do in the IFC for improved usability.

It should be noted that fuel cell power systems are being actively marketed and installed for one- and two-family homes. This has been occurring for over a decade. Fuel cell powered electric vehicles are also now being marketed with the capability to be used as an ESS for a dwelling unit.

To better address these specialty systems the following is proposed:

**Definition:** The definition and subdefinitions for stationary fuel cell power systems has been brought over from the IFC.

**New R328.1:** Requires compliance with this section of the IRC and Section 1205 of the IFC where the bulk of the requirements are located. For temporary use of fuel cell powered vehicles as ESS it points to Section R328.3.

**New R328.2:** Identifies that only residential use listed fuel cell power systems can be installed in dwelling units.

**New R328.3:** Provides for the temporary use of the fuel cell powered electric vehicles to power the dwelling. It is limited to the owner or occupant's vehicle. This is an important distinction as mobile ESS providers are regulated by the IFC.

**New R328.3.1:** Defines how long the 'temporary' use is.

The language added is intentionally not extensive. The core requirements for these specialty systems are already built into the IFC and the referenced standards of that document. When installed as ESS the requirements for ESS in this code will also apply. The language proposed is enough to ensure proper installation and to address the temporary use of fuel cell powered vehicles as ESS.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposed change does not impact the cost of construction of one- or two-family dwellings and townhouses. Stationary fuel cell power systems are specialty systems typically installed in an existing dwelling by the current owner. In the rare case that a new custom home owner desires installation of a stationary fuel cell power system as part of the construction of the custom home, these requirements impact the cost of the stationary fuel cell power system portion of the installation, not the cost of construction of the home itself.

RB160-19

---

ICC COMMITTEE ACTION HEARINGS :: April, 2019

---

RB367
2018 International Residential Code

Add new text as follows:

**R328**

**Physical Security**

R328.1 **Purpose.** The purpose of this section is to establish minimum standards that incorporate physical security to make dwelling units resistant to unlawful entry.

R328.1.1 **Scope.** The provisions of this section shall apply to all new structures and to additions and alterations made to existing buildings.

R328.2 **Doors.** All exterior swinging doors of residential dwelling units and attached garages, including doors leading from the garage area into the dwelling unit, shall comply with Sections R328.2.1 through R328.2.5 based on the type of door installed.

**Exception:** Vehicular access doors

R328.2.1 **Wood doors.** Exterior wood doors shall be of solid core construction such as high-density particleboard, solid wood, or wood block core with a minimum thickness of 1-3/4 inches (45 mm) at any point. Doors with panel inserts shall be solid wood with the insert being a minimum of 1-inch (25.4 mm) in thickness.

R328.2.2 **Steel doors.** Exterior steel doors shall be a minimum thickness of 24 gauge and have reinforcement material at the location of the deadbolt.

R328.2.3 **Fiberglass doors.** Fiberglass doors shall have a minimum skin thickness of one-sixteenth inch and have reinforcement material at the location of the deadbolt.

R328.2.4 **Double doors.** The inactive leaf of an exterior double door shall be provided with flush bolts having an engagement of not less than 1-inch (25.4 mm) into the head and threshold of the doorframe, or by other approved methods.

R328.2.5 **Sliding doors.** Exterior sliding doors shall be installed to prevent the removal of the panels from the exterior.

R328.3 **Door frames.** The exterior door frames shall be installed prior to the rough-in inspection. Horizontal blocking shall be placed between studs at the door lock height for three stud spaces or equivalent bracing on each side of the door opening. Door frames shall comply with Sections R328.3.1 through R328.3.2 based on the type of door installed.

R328.3.1 **Wood frames.** Wood frame doors shall be set in frame openings constructed of double studding or equivalent construction. Door frames, including those with sidelights, shall be reinforced in accordance with ASTM F476 Grade 40 bolt and hinge impact only.
R328.3.2 Steel frames. Steel door frames shall be constructed of 18 gauge or heavier steel and reinforced at the hinges and strikes. Doors are to be anchored to the wall in accordance with the manufacturer’s instructions.

R328.4 Door jambs. Door jambs on wooden jambs for in-swinging doors shall be of one-piece construction.

R328.5 Door hardware. Exterior door hardware shall comply with Sections R328.5.1 through R328.5.5.

R328.5.1 Hinges. Hinges for exterior swinging doors shall comply with the following:

1. At least two screws, 3 inches (76 mm) in length, penetrating at least 1-inch (25.4 mm) into the wall structure shall be used. Solid wood fillers or shims shall be used to eliminate any space between the wall structure and the door frame behind each hinge.
2. Hinges for out-swinging doors shall be equipped with mechanical interlock to prevent removal of the door from the exterior.

R328.5.2 Escutcheon plates. All exterior doors shall have escutcheon plates protecting the door’s edge.

R328.5.3 Locks. Exterior doors shall be provided with a deadbolt with a minimum grade 2 as determined by ANSI/BHMA.

R328.5.4 Entry vision and glazing. All main or front entry doors to dwelling units shall be arranged so that the occupant has a view of the area immediately outside the door without opening the door. The view may be provided by a door viewer having a field of view of not less than 180 degrees, through windows or through view ports.

R328.5.5 Side light entry doors. Side light doors units shall have framing of double stud construction or equivalent construction complying with Sections R328.3.1 or R328.3.2. The door frame that separates the door opening from the side light, whether on the latch side or the hinge side, shall be double stud construction or equivalent construction complying with Sections R328.3.1 or R328.3.2. Double stud construction or equivalent construction shall exist between the glazing unit of the side light and the wall structure of the dwelling.

R328.6 Alternate materials and methods of construction. The provisions of this section are not intended to prevent the use of any material or method of construction not specifically prescribed by this section, provided any such alternate has been approved. Nor is it the intention of this section to exclude any sound method of structural design or analysis not specifically provided for in this section. The materials, method of construction and structural design limitations provided for in this section shall be used, unless otherwise approved. Compliance with ASTM F476 will be deemed to be in compliance with this section.

Reason: In the summer of 1996, Overland Park, Kansas, experienced a series of home invasions resulting in the sexual assault of several women. For the victims of a home invasion, it’s more than a property crime; it scares the victim into thinking that the criminal will return only to commit a more violent or heinous crime. To have an emotional investment in their residence is priceless.

As a result of these home invasions, the City’s Police Department conducted hundreds of surveys of residents in an effort to develop a solution to the home invasions. The results of the surveys lead the City to develop a building code that makes home more safe and secure. You may ask, why secure the front door? What about installing an alarm? Communities across the country continue to report a growing increase in false alarms. In an effort to provide physical security to the homeowner, there needs to be a more reliable option available.

The longer a criminal spends trying to gain access to a home, the greater the risk of detection. In addition, most home invaders will not attempt to break a window, as that makes noise that neighbors could potentially hear. Rather than face these risks, the invader is more likely to try to kick in an exterior door, where they can easily gain access without being detected.

This code change will provide for minimal provisions to be made to a new home under construction that will give
the homeowner safety and peace of mind, while delaying and frustrating the criminal. Since this proposal is not dependent on electrical power, these provisions will always be available to the homeowner and will require no further action after installation. There is no on-going cost to the homeowner and these provisions will not affect the overall aesthetics of the home.

Cost Impact: The code change proposal will increase the cost of construction
The cost to secure a single door ranges from $40-$60 for a single door unit and between $140 and $180 for a double sidelite unit.

Staff Analysis: A review of the standard proposed for inclusion in the code, ASTM F476, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 4863

RB161-19
2018 International Residential Code

Add new definition as follows:

**VEHICULAR GATE.** A moveable barrier that is intended for use at a vehicle entrance or exit and not intended for use by pedestrian traffic.

Add new text as follows:

**R328.1 General.** Automatic vehicular gates shall comply with the requirements of Sections R328.2 and R328.3.

**R328.2 Vehicular gates intended for automation.** Vehicular gates intended for automation shall be designed, constructed and installed to comply with the requirements of ASTM F2200.

**R328.3 Vehicular gate openers.** Vehicular gate openers shall be listed in accordance with UL 325.

Add new standard(s) as follows:

**ASTM**

F2200-14: Standard Specification for Automated Vehicular Gate Construction

Delete without substitution:

**SECTION AO101—GENERAL**

**AO101.1 General.** The provisions of this appendix shall control the design and construction of automatic vehicular gates installed on the lot of a one- or two-family dwelling.

**SECTION AO102—DEFINITION**

**VEHICULAR GATE.** A gate that is intended for use at a vehicular entrance or exit to the lot of a one- or two-family dwelling, and that is not intended for use by pedestrian traffic.

**SECTION AO103—AUTOMATIC VEHICULAR GATES**

**AO103.1 Vehicular gates intended for automation.** Vehicular gates intended for automation shall be designed, constructed and installed to comply with the requirements of ASTM F2200.

**AO103.2 Vehicular gate openers.** Vehicular gate openers, where provided, shall be listed in accordance with
**SECTION AO104 REFERENCED STANDARDS**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
<th>AO103.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASTM F2200</td>
<td>Standard Specification for Automated Vehicular Gate Construction</td>
<td>AO103.1</td>
</tr>
<tr>
<td>UL 325—02</td>
<td>Door, Drapery, Gate, Louver and Window Operations and Systems—with revisions through May 2015</td>
<td>AO103.2</td>
</tr>
</tbody>
</table>

**Reason:** This proposal recognizes the importance of safety by moving the requirements for automatic vehicular gates from Appendix O to the body of the code. It does not require the use of automated vehicular gates, but where vehicular gates are provided, it requires them to meet the same safety standards that are in the IBC (Section 3110) and the IFC (Sections 503.5 and 503.6.).

In 2018, CPSC launched “Operation Safe Gate” to put an end to preventable tragedies caused by automatic security gates. CPSC estimates that there are about 300 emergency room injuries each year due to automatic gates. Many of the injuries have been serious and resulted in cuts, broken bones, hematomas and amputations. In addition, CPSC has received four tragic reports of fatalities in recent years, including an 8 year old, an 11 year old and a 12 year old.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

This proposal does not require vehicular gates to be installed. There are numerous automated vehicular gates that already comply with these safety standards, so when these are used there will be no increase in costs.

Proposal # 4230

RB162-19
SECTION R328
ALTERATIONS AND ADDITIONS

R328.1 General. Additions and Alterations to detached one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories above grade plane in height with a separate means of egress, and their accessory structures not more than three stories above grade plane in height, shall comply with this code or the International Existing Building Code. Where the alteration includes a change of use or occupancy to one not within the scope of the International Residential Code, the alteration shall comply with the International Existing Building Code.

R328.2 Additions. Additions to buildings within the scope of the International Residential Code shall comply with the requirements of the International Residential Code for new construction. Alterations to the existing building or structure shall be such that the existing building or structure together with the addition is not less compliant with the provisions of the International Residential Code than the existing building or structure was prior to the addition. An existing building together with its additions shall comply with the height limits of the International Residential Code.

R328.3 Alterations. Alterations to any building or structure within the scope of the International Residential Code shall comply with the requirements of the International Residential Code for new construction. Alterations shall be such that the existing building or structure is not less compliant with the provisions of the International Residential Code than the existing building or structure was prior to the alteration.

Reason: This proposed code change is editorial in nature and cross reference the IEBC in similar fashion to the way the IEBC provides the IRC as an option for compliance in the exception to Section 101.2. The code change also fills a gap regarding additions and alterations since the two scopes of work that are defined in Chapter 2 are only used within specific sections such as smoke alarm and carbon monoxide alarm requirements for example. The proposed general text is extracted from the IEBC prescriptive method sections in chapter 5. The alterations section also clarifies that you only need to go to the IEBC if the alteration changes the occupancy or use to one not regulated by the IRC.

Chapter 3 was selected in lieu of chapter 1 since some jurisdictions may not adopt Chapter 1 of the IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposed code change is editorial in nature and does not add new standards.
2018 International Residential Code

</tbody>
</table>
For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m².

a. Interpolation allowed.– Linear interpolation of footing width is permitted between the soil bearing pressures in the table. Extrapolation is not allowed.

b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2 feet of adjustment to the width of the house, add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick). The table is based on the following conditions and loads: Building width: 32 feet; Wall height: 9 feet; Basement wall height: 8 feet; Dead loads: 15 psf roof and ceiling assembly, 10 psf floor assembly, 12 psf wall assembly; Live loads: Roof and ground snow loads as listed, 40 psf first floor, 30 psf second and third floor. Footing sizes are calculated assuming a clear span roof/ceiling assembly and an interior bearing wall or beam at each floor.

c. Where the building width perpendicular to the wall footing is greater than 32 feet, the footing width shall be increased by 2 inches and footing depth shall be increased by 1 inch for every 4 feet of increase in building width.

d. Where the building width perpendicular to the wall footing is less than 32 feet, a 2 inch decrease in footing width and 1 inch decrease in footing depth is permitted for every 4 feet of decrease in building width.

</table>

a. Interpolation allowed. Linear interpolation of footing width is permitted between the soil bearing pressures in the table. Extrapolation is not allowed permitted.

b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2 feet of adjustment to the width of the house, add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick). The table is based on the following conditions and loads: Building width: 32 feet; Above-grade wall height: 9 feet; Slab-on-grade stem wall height: 1 foot; Crawlspace wall height: 4 feet; Dead loads: 15 psf roof and ceiling assembly, 10 psf floor assembly, 45 psf wall assembly; Live loads: Roof and ground snow loads as listed, 10 psf attic floor; 40 psf first floor, 30 psf second and third floor. Footing sizes are calculated assuming a clear span roof/ceiling assembly and an interior bearing wall or beam at each floor.

c. Where the building width perpendicular to the wall footing is greater than 32 feet, the footing width shall be increased by 2 inches and footing depth shall be increased by 1 inch for every 4 feet of increase in building width.

d. Where the building width perpendicular to the wall footing is less than 32 feet, a 2 inch decrease in footing width and 1 inch decrease in footing depth is permitted for every 4 feet of decrease in building width.

</table>

For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m².

a. Interpolation allowed. Linear interpolation of footing width is permitted between the soil bearing pressures in the table. Extrapolation is not allowed.

b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2 feet of adjustment to the width of the house add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick). The table is based on the following conditions and loads: Building width: 32 feet; Above-grade wall height: 9 feet; Slab-on-grade stem wall height: 1 foot; Crawlspace wall height: 4 feet; Dead loads: 15 psf roof and ceiling assembly, 10 psf floor assembly, 100 psf wall assembly; Live loads: Roof and ground snow loads as listed, 10 psf attic floor, 40 psf first floor, 30 psf second and third floor. Footing sizes are calculated assuming a clear span roof/ceiling assembly and an interior bearing wall or beam at each floor.

c. Where the building width perpendicular to the wall footing is greater than 32 feet, the footing width shall be increased by 2 inches and footing depth shall be increased by 1 inch for every 4 feet of increase in building width.

d. Where the building width perpendicular to the wall footing is less than 32 feet, a 2 inch decrease in footing width and 1 inch decrease in footing depth is permitted for every 4 feet of decrease in building width.
R403.1.1 Minimum size. The minimum width, $W$, and thickness, $T$, for concrete footings shall be in accordance with Tables R403.1(1) through R403.1(3) and Figure R403.1(1) or R403.1.3, as applicable but not less than 12 inches (305 mm) in width and 6 inches (152 mm) in depth. The footing width shall be based on the load-bearing value of the soil in accordance with Table R401.4.1. Footing projections, $P$, shall be not less than 2 inches (51 mm) and shall not exceed the thickness of the footing. Footing thickness and projection for fireplaces shall be in accordance with Section R1001.2. The size of footings supporting piers and columns shall be based on the tributary load and allowable soil pressure in accordance with Table R401.4.1. Footings for wood foundations shall be in accordance with the details set forth in Section R403.2, and Figures R403.1(2) and R403.1(3). Footings for precast foundations shall be in accordance with the details set forth in Section R403.4, Table R403.4, and Figures R403.4(1) and R403.4(2).

Reason: Builders using the new footing tables introduced in the 2015 IRC have found the footing widths required by the table are significantly larger than those required by previous editions of Table R403.1, which dated back to the CABO codes. In many cases they were wider than an engineering analysis would suggest. A careful review of the calculations underlying the 2015 IRC tables found a number of cases where load assumptions and determinations were overly conservative, and a few cases where the calculations were actually unconservative. Problems with the assumptions and calculations included the following:

- The original calculations apply the full ground snow load to the roof. The actual roof snow load per ASCE 7, unadjusted by any other factors, is 70% of the ground snow load or 20 pounds per square foot, whichever is greater. Consistent with the Chapter 8 rafter tables, a thermal factor of 1.1 per ASCE 7 is applied to the calculation of the snow load.
- The original calculations apply a 100 pound per square foot weight for above-grade concrete or masonry walls, representing a solid or fully-grouted 8” CMU wall. Such walls are more likely to be either 8” CMU with reinforcing @ 48” o.c. or 8” insulated concrete forms, both of which have a 55 pound per square foot weight.
- The original calculations use only the ASCE 7 load combination that applies a 0.75 factor for concurrent roof/snow and floor live loads, ignoring the load combinations that apply just the roof/attic LL, just the snow load, or just the total floor live loads.
- The original calculations are based on tributary width, yet Footnote #2 adds 2 inches of footing width for every 2 feet of additional building width. As a result of confusing building and tributary width, the footnote adds twice as much footing width as is necessary based on the loads!

Other key changes in the revised code text and footing tables include:

- The original footnote allowing footing width and depth to be adjusted is converted into two footnotes. One footnote requires an increase in footing width and depth when the building width perpendicular to a wall footing exceeds 32 feet. The second footnote permits, but does not require, a decrease in footing width and depth for a building width of 32 feet or narrower.
- The charging text is revised to clarify the minimum width of a footing shall not be less than 12 inches and depth shall not be less than 6 inches. Previously, the limitation on depth was buried in a footnote.

These revised tables correct the inconsistencies in the load assumptions and calculations. The result in many cases is footing widths for one- and two-family dwellings that are more in line with historic practice, while still technically justified under engineering standards and accepted practices. However, it is noted there are cases for houses on weaker soils (1500 and 2000 psf soil bearing strength) as well as for slab-on-grade and crawlspace houses, where corrections to the calculations, the assumption of clear-spanning roof trusses, and other changes to the assumptions increase the loads sufficiently to increase the footing widths.

Cost Impact: The code change proposal will increase the cost of construction. The revised tables increase footing sizes and depths for houses on weaker soils and slab-on-grade or crawlspace houses due to the revised calculations imposing larger loads on the footings. In other cases,
correcting overly conservative assumptions result in modest reductions in footing size. Also, this proposal improves clarity regarding the base assumptions, which may allow more dwellings to be constructed using the table rather than having to rely on engineered design or other, more conservative, engineering-based prescriptive standards, thus some builders may save on both footing size and avoid engineering design fees.

Proposal # 4940
**2018 International Residential Code**

**Revise as follows:**

**TABLE R403.1(1)**

MINIMUM WIDTH AND THICKNESS FOR CONCRETE FOOTINGS FOR LIGHT-FRAME CONSTRUCTION (inches)<sup>a, b</sup>

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>SNOW LOAD OR ROOF LIVE LOAD</th>
<th>STORY AND TYPE OF STRUCTURE WITH LIGHT FRAME</th>
<th>LOAD-BEARING VALUE OF SOIL (psf)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1500 2000 2500 3000 3500 4000</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m<sup>2</sup>.

a. Interpolation allowed. Extrapolation is not allowed.
b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2 1/4 feet of adjustment to the width of the house, add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick).

**TABLE R403.1(2)**

MINIMUM WIDTH AND THICKNESS FOR CONCRETE FOOTINGS FOR LIGHT-FRAME CONSTRUCTION WITH BRICK VENEER (inches)<sup>a, b</sup>

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>SNOW LOAD OR ROOF LIVE LOAD</th>
<th>STORY AND TYPE OF STRUCTURE WITH BRICK VENEER</th>
<th>LOAD-BEARING VALUE OF SOIL (psf)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1500 2000 2500 3000 3500 4000</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m<sup>2</sup>.

a. Interpolation allowed. Extrapolation is not allowed.
b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2 1/4 feet of adjustment to the width of the house, add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick).

**TABLE R403.1(3)**

MINIMUM WIDTH AND THICKNESS FOR CONCRETE FOOTINGS WITH CAST-IN-PLACE CONCRETE OR FULLY GROUTED MASONRY WALL CONSTRUCTION (inches)<sup>a, b</sup>

Portions of table not shown remain unchanged.
For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m².

a. Interpolation allowed. Extrapolation is not allowed.

b. Based on 32-foot-wide house with load-bearing center wall that carries half of the tributary attic, and floor framing. For every 2.4 feet of adjustment to the width of the house add or subtract 2 inches of footing width and 1 inch of footing thickness (but not less than 6 inches thick).

**Reason:** Builders using the new footing tables introduced in the 2015 IRC have found the footing widths required by the table are significantly larger than those required by previous editions of Table R403.1, which dated back to the CABO codes. In many cases they were wider than an engineering analysis would suggest for a house of the same size, configuration, and foundation conditions. In particular, footing sizes for houses greater than 32 feet in width generated using footnote (b) calling for the footing to be increased by 2 inches in width and 1 inch in depth for every 2 feet of increase in building width were significantly higher than those obtained from the traditional table or by an engineering analysis.

A careful review of the calculations underlying the 2015 IRC tables found a number of cases where load assumptions and determinations were overly conservative, and a few cases where the calculations were actually unconservative. As part of this review, it was noted the spreadsheet used to generate the tables for the 2015 IRC is based on entering the tributary width, or half the distance between the exterior bearing wall and an interior bearing wall or ridge board, yet footnote (b) specifies 2 inches of footing width shall be added for every 2 feet of additional building width. It was clear from the spreadsheet that increasing the tributary width by 2 feet did generally increase the footing width by 2 inches and in many cases the depth by 1 inch. However, a 2 foot increase in tributary width actually translates to a 4 foot increase in building width. As a result, the footnote leads to users increasing the footing width and depth at twice the rate that is necessary based on the actual increase in loads.

If no other adjustment is made to the tables, changing the footnote to reflect the correct rate at which the footing size and depth increases with building width will reduce the overly conservative size of footings generated by the current footnote for houses of portions of houses wider than 32 feet.

**Cost Impact:** The code change proposal will decrease the cost of construction

The code change will decrease the cost of construction for dwellings or portions thereof larger than 32 feet in width where the current footnote increases footing widths and depths at twice the rate that would be required based on the underlying engineering calculations, let alone the footing width and depth that would be determined based on a dwelling-specific engineering analysis. If code users were taking advantage of the footnote for dwellings narrower than 32 feet costs may increase as the footing size would also be reduced at a slower rate. However, it is not known how many users are refining the footing size to that degree.

Proposal # 4810

RB165-19
R403.1.6 Foundation anchorage. Wood sill plates and wood walls supported directly on continuous foundations shall be anchored to the foundation in accordance with this section. Cold-formed steel framing shall be anchored directly to the foundation or fastened to wood sill plates in accordance with Section R505.3.1 or R603.3.1, as applicable. Wood sill plates supporting cold-formed steel framing shall be anchored to the foundation in accordance with this section.

Wood sole plates at all exterior walls on monolithic slabs, wood sole plates of braced wall panels at building interiors on monolithic slabs and all wood sill plates shall be anchored to the foundation with minimum 1/2-inch-diameter (12.7 mm) anchor bolts spaced not greater than 6 feet (1829 mm) on center or approved anchors or anchor straps spaced as required to provide equivalent anchorage to 1/2-inch-diameter (12.7 mm) anchor bolts. Bolts shall extend not less than 7 inches (178 mm) into concrete or grouted cells of concrete masonry units. The bolts shall be located in the middle third of the width of the plate. A nut and washer shall be tightened on each anchor bolt. There shall be not fewer than two bolts per plate section with one bolt located not more than 12 inches (305 mm) or less than seven bolt diameters from each end of the plate section. Interior bearing wall sole plates on monolithic slab foundation that are not part of a braced wall panel shall be positively anchored with approved fasteners. Sill plates and sole plates shall be protected against decay and termites where required by Sections R317 and R318. Anchor bolts shall be located after the concrete is placed and before it has set in accordance with ACI 332.

Exceptions:

1. Walls 24 inches (610 mm) total length or shorter connecting offset braced wall panels shall be anchored to the foundation with not fewer than one anchor bolt located in the center third of the plate section and shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).
2. Connection of walls 12 inches (305 mm) total length or shorter connecting offset braced wall panels to the foundation without anchor bolts shall be permitted. The wall shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).

R404.1.3.3.6 Form materials and form ties. Forms shall be made of wood, steel, aluminum, plastic, a composite of cement and foam insulation, a composite of cement and wood chips, or other approved material suitable for supporting and containing concrete. Forms shall be accurately positioned and secured before placing concrete and shall provide sufficient strength to contain concrete during the concrete placement operation.

Form ties shall be steel, solid plastic, foam plastic, a composite of cement and wood chips, a composite of cement and foam plastic, or other suitable material capable of resisting the forces created by fluid pressure of fresh concrete.

Reason: ACI 332 Residential Code Requirements for Structural Concrete and Commentary is a standard used for residential concrete construction. Many residential foundation installations include “wet-set” anchor bolts to attach wood sills to foundations. This code change will codify a common practice that is not recognized as an
accepted practice in ACI 318 Building Code Requirements for Structural Concrete and Commentary but is allowed in ACI 332. In some cases, “wet-setting” the anchor bolt is the only method by which the bolt can be placed. Insulated concrete forms (ICF’s) as well as Concrete Masonry Units (CMU) allow this type of installation. The code change is limited to the wet setting of the anchor bolt connection to the wood sill. Forms that are to be embedded would need to be tied down or secured prior to the concrete pour.

Cost Impact: The code change proposal will decrease the cost of construction. It will reduce the labor and time in foundation construction in one and two family dwellings.
2018 International Residential Code

Revise as follows:

R403.1.6 Foundation anchorage. Wood sill plates and wood walls supported directly on continuous foundations shall be anchored to the foundation in accordance with this section. Cold-formed steel framing shall be anchored directly to the foundation or fastened to wood sill plates in accordance with Section R505.3.1 or R603.3.1, as applicable. Wood sill plates supporting cold-formed steel framing shall be anchored to the foundation in accordance with this section.

Wood sole plates at all exterior walls on monolithic slabs, wood sole plates of braced wall panels at building interiors on monolithic slabs and all wood sill plates shall be anchored to the foundation with minimum 1/2-inch-diameter (12.7 mm) anchor bolts spaced not greater than 6 feet (1829 mm) on center or approved anchors or anchor straps spaced as required to provide equivalent anchorage to 1/2-inch-diameter (12.7 mm) anchor bolts. Bolts shall extend not less than 7 inches (178 mm) into concrete or grouted cells of concrete masonry units. The bolts shall be located in the middle third of the width of the plate. A nut and washer shall be tightened on each anchor bolt. There shall be not fewer than two bolts per plate section with one bolt located not more than 12 inches (305 mm) or less than seven bolt diameters from each end of the plate section. Interior bearing wall sole plates on monolithic slab foundation that are not part of a braced wall panel shall be positively anchored with approved fasteners. Sill plates and sole plates shall be protected against decay and termites where required by Sections R317 and R318.

Exceptions:

1. Walls 24 inches (610 mm) total length or shorter connecting offset braced wall panels shall be anchored to the foundation with not fewer than one anchor bolt located in the center third of the plate section and shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).
2. Connection of walls 12 inches (305 mm) total length or shorter connecting offset braced wall panels to the foundation without anchor bolts shall be permitted. The wall shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).
3. Where field conditions prohibit the placement of the minimum required bottom plate anchors, a registered design professional shall provide a design for the attachment in accordance with accepted engineering practice.

Reason: Bottom plate is preferentially referenced in lieu of sill plate to match that same evolution in the IBC and AF&PA references. In residential construction many times there are short length wall framing for door openings, exterior built-up columns and post framing and similar construction where it is impractical to comply with the R403.1.6 completely. The exception is provided to explicitly allow a design professional the ability to design appropriate attachment for these conditions. Insertion within the “Foundation anchorage” requirements, section R403.1.6 is to clarify that this change also applies to prescriptive design requirements.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal simply adds an additional accepted method of attachment by allowing a registered design professional to determine placement of foundation anchorage based on field conditions.
2018 International Residential Code

#### Reason:
To add some uniformity to the IRC Code, the following modification is proposed to the Table headers. Section R404.1 applies to foundation walls, which could be constructed with either masonry or concrete. Since the creation of the IRC, the masonry and concrete wall sections have been written and modified by different interest groups. In some instances there has been a lack of coordination between code provisions for the two materials. This is an attempt to bridge some of those differences so that the users of the IRC can see uniform language across the code.

It is proposed that all affected Tables use the header "MAXIMUM UNSUPPORTED WALL HEIGHT" to describe these similar conditions.

#### Cost Impact:
The code change proposal will not increase or decrease the cost of construction
No change in the design requirements, simply an attempt to unify language across material sections.

Proposal # 4605

RB168-19
2018 International Residential Code

Revise as follows:

**R404.1.2.1 Masonry foundation walls.** Concrete masonry and clay masonry foundation walls shall be constructed as set forth in Table R404.1.1(1), R404.1.1(2), R404.1.1(3) or R404.1.1(4) and shall comply with applicable provisions of Section R606. In buildings assigned to Seismic Design Categories D₀, D₁ and D₂, concrete masonry and clay masonry foundation walls shall also comply with Section R404.1.4.1. Rubble stone masonry foundation walls shall be constructed in accordance with Sections R404.1.8 and R606.4.2. Rubble stone masonry walls shall not be used in Seismic Design Categories D₀, D₁ and D₂.

**Reason:** For rubble stone masonry walls, the limit set forth in this section conflicts with the limitations contained in Section R404.1.8. Section R404.1.8 prohibits rubble stone masonry walls in Seismic Categories D₀, D₁ and D₂, as indicated in this section, but it also prohibits the use in Townhouses in Seismic Design Category C. The intent of this proposal is to align the two code sections. The sentence prior to the struck text already requires the user to refer to Section R404.1.8 for all rubble walls, so there should be no harm in removing the conflicting sentence.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. No changes to the design requirements for rubble stone masonry are proposed.
**2018 International Residential Code**

Add new text as follows:

**R404.1.3.6.2 Removal of form ties** Form ties shall be removed from both faces of the foundation walls which enclose basements or other enclosed habitable and occupiable spaces. Remaining holes shall be parged with hydraulic cement, portland cement, or any other approved material.

**Reason:** Modern concrete foundation installation practices frequently utilize form ties. When the forms are removed, the ends of the form ties are typically removed, and a cone or hole remains in the place of the old end. The metal form tie is still remaining in the wall, and may be subject to corrosion due to acidity of the soil and exposure to water. Many builders already implement parging and sealing these holes with cementitious products as a best practice. This proposal will codify a current industry best practice. The requirement is only applicable to areas that may be subject to human contact where items can be damaged due to resulting moisture.

**Cost Impact:** The code change proposal will increase the cost of construction

This code change proposal may minimally increase the cost of construction by implementing a current best practice. Where the affected holes are so small, the resulting cost increase is expected to be minimal.
2018 International Residential Code

Revise as follows:

R404.1.3.3.7.1 Steel reinforcement. Steel reinforcement shall comply with the requirements of ASTM A615, A706, or A996. ASTM A996 bars produced from rail steel shall be Type R. In buildings assigned to Seismic Design Category A, B or C, the minimum yield strength of reinforcing steel shall be 40,000 psi (Grade 40) (276 MPa). In buildings assigned to Seismic Design Category D, D1 or D2, reinforcing steel shall comply with the requirements of ASTM A706 for low alloy steel with a minimum yield strength of shall be 60,000 psi (Grade 60) (414 MPa).

Reason: The proposal is intended to remove the unnecessary requirement for the use of A706 reinforcing steel in non-demand critical residential foundation walls. ASTM A706 reinforcing steel was developed to address the need to have reinforcing steel with controlled tensile properties for earthquake-resisting structures and controlled chemical composition for weldability. When looking at the American Concrete Institute Building Code Requirements for Structural Concrete (ACI 318-14), deformed bars of either A615, A706 or A996 are allowed for foundation walls (ACI 318-14, Section 20.2.1.3). ACI 318-14, Section 20.2.2.5 places requirements on the reinforcing steel grade for longitudinal reinforcement used to resist earthquake-induced forces in special moment frames, special structural walls and components of structural walls. Residential foundation walls, as those specified in IRC Section R404.1.3 are not elements that are expected to experience the inelastic demands that necessitate the need for the ductility that is provided for with A706 reinforcing.

Bibliography: American Concrete Institute Building Code Requirements for Structural Concrete (ACI 318-14), Sections 20.2.1.3 and 20.2.2.5

Cost Impact: The code change proposal will decrease the cost of construction
Will remove requirement for higher grade of reinforcing steel for residential foundations.

Proposal # 4608

RB171-19
IRC: R404.1.10 (New)

Proponent: Josh OConnor, representing Self (joshoc@aol.com)

2018 International Residential Code

Add new text as follows:

**R404.1.10 HVAC connection opening.** Where a dwelling unit has HVAC equipment or appliances that are located exterior to the dwelling unit and next to the foundation wall, openings through the foundation wall shall be sized so that the supply and return air connections are not reduced in area.

**Reason:** I have seen that national home builders are only making this opening 32 inches wide, and that is not wide enough for the supply and return air flex ducts to come off of the back of a packaged HVAC unit without having to veer in sharply to enter the foundation opening. This causes pinching which restricts airflow. HVAC manufacturers make the openings/ports on the back of the packaged units further apart than 32 inches. Because the units are forced to sit very close to the house the supply and return air ducts need a straight run off of the unit into the foundation opening, and the opening has to be wide enough to allow this. At a relative’s house, I saw the inside of a supply duct pinched to half of its normal diameter because of having to veer off of the unit into a foundation opening that was only 32 inches wide.

**Bibliography:**

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There will be no change to construction requirements. This is a coordination issue.

Proposal # 3896
**2018 International Residential Code**

Revise as follows:

**R406.2 Concrete and masonry foundation waterproofing.** In areas where a high water table or other severe soil-water conditions are known to exist, exterior foundation walls that retain earth and enclose interior spaces and floors below grade shall be waterproofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished grade. Walls shall be waterproofed in accordance with one of the following:

1. Two-ply hot-mopped felts.
2. Fifty-five-pound (25 kg) roll roofing.
3. Six-mil (0.15 mm) polyvinyl chloride.
4. Six-mil (0.15 mm) polyethylene.
5. Forty-mil (1 mm) polymer-modified asphalt.
6. Sixty-mil (1.5 mm) flexible polymer cement.
7. One-eighth-inch (3 mm) cement-based, fiber-reinforced, waterproof coating.
8. Sixty-mil (1.5 mm) solvent-free liquid-applied synthetic rubber.

All joints in membrane waterproofing shall be lapped and sealed with an adhesive compatible with the membrane.

**Exception:** Organic-solvent-based products such as hydrocarbons, chlorinated hydrocarbons, ketones and esters shall not be used for ICF walls with expanded polystyrene form material. Use of plastic roofing cements, acrylic coatings, latex coatings, mortars and pargings to seal ICF walls is permitted. Cold-setting asphalt or hot asphalt shall conform to Type C of ASTM D449. Hot asphalt shall be applied at a temperature of less than 200°F (93°C).

**Reason:** Section R406 is amended by deleting Items 3 and 4 from the list of approved products that can be used as a waterproofing material. Both 6 mil poly vinyl chloride and 6 mil polyethylene products, do not have the thickness and strength to be effective and durable waterproofing products, during construction of a foundation, especially during backfilling of the foundations. Waterproofing is the formation of a durable and impervious barrier designed to prevent water from entering a specific section or sections of the building envelope system (i.e. Foundations). To be effective, a waterproofing system consists of a durable and continuous material applied to all areas of the foundation, subject to hydrostatic pressure. Typically, during backfill, other materials are improperly placed along the foundation; materials containing debris, frost, sharp stones, rocks and/or items that will rip and tear the 6 mil products. When the back fill materials are not placed properly, 6 mil poly, used as waterproofing, will create durability issues. These holes allow water to get behind the waterproofing material and trap it there. This creates moisture issues on the interior of the building. The other products as listed in the code allowed as a waterproofing material, are all made of heavy materials that are more resistant to tearing or ripping during backfill, such as 50 pound materials or at a minimum, 40 mil in thickness. It is reasonable to take out a product that is not performing as it is intended. This will increase the cost of construction of the home, but this cost will be offset with savings in the reduction of service calls and repairs for moisture mold and mildew issues.

**Cost Impact:** The code change proposal will increase the cost of construction

**Proponent:** donald sivigny, State of MN, representing State of MN and Association of Minnesota Building Officials (don.sivigny@state.mn.us)
This will increase the cost of construction of the Home by requiring a more durable product be used on the 
foundation wall. However, this cost will be offset with any savings in the reduction of service calls and repairs for 
moisture mold and mildew issues. The Typical Service call costs a Builder a minimum of $350 on average. Call 
backs for wet basements or mold and mildew are frequent and numerous, costing builders of today a lot of time 
and money to solve the Problem. Removal of these non-durable products will save money in the long run and 
perform better for the building.
2018 International Residential Code

Revise as follows:

R406.2 Concrete and masonry foundation waterproofing. In areas where a high water table or other severe soil-water conditions are known to exist, exterior foundation walls that retain earth and enclose interior spaces and floors below grade shall be waterproofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished grade. Walls shall be waterproofed in accordance with one of the following:

1. Two-ply hot-mopped felts.
2. Fifty-five-pound (25 kg) roll roofing.
3. Six-mil (0.15 mm) polyvinyl chloride.
4. Six-mil (0.15 mm) polyethylene.
5. Forty-mil (1 mm) polymer-modified asphalt.
6. Sixty-mil (1.5 mm) flexible polymer cement.
7. One-eighth-inch (3 mm) cement-based, fiber-reinforced, waterproof coating.
8. Sixty-mil (1.5 mm) solvent-free liquid-applied synthetic rubber.
9. A drainage layer of not less than 4 inches (102 mm) of free draining granular material.
10. A drainage layer that provides equivalent performance to not less than 4 inches (102 mm) of free draining granular material.

All joints in membrane waterproofing shall be lapped and sealed with an adhesive compatible with the membrane.

**Exception:** Organic-solvent-based products such as hydrocarbons, chlorinated hydrocarbons, ketones and esters shall not be used for ICF walls with expanded polystyrene form material. Use of plastic roofing cements, acrylic coatings, latex coatings, mortars and pargings to seal ICF walls is permitted. Cold-setting asphalt or hot asphalt shall conform to Type C of ASTM D449. Hot asphalt shall be applied at a temperature of less than 200°F (93°C).

**Reason:** Objective:
Provide more options for foundations waterproofing and dampproofing.

This code change provides additional options for foundation waterproofing and dampproofing.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
This provides additional options. Options seldom add costs and sometimes can reduce costs.

Proposal # 5428
2018 International Residential Code

R406.1 Concrete and masonry foundation dampproofing. Except where required by Section R406.2 to be waterproofed, foundation walls that retain earth and enclose interior spaces and floors below grade shall be dampproofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished grade. Masonry walls shall have not less than 3/8-inch (9.5 mm) Portland cement parging applied to the exterior of the wall. The parging shall be dampproofed in accordance with one of the following:

1. Bituminous coating.
2. Three pounds per square yard (1.63 kg/m²) of acrylic modified cement.
3. One-eighth-inch (3.2 mm) coat of surface-bonding cement complying with ASTM C887.
4. Any material permitted for waterproofing in Section R406.2.
5. Other approved methods or materials.

Exception: Parging of unit masonry walls is not required where a material is approved for direct application to the masonry.

Concrete walls shall be dampproofed by applying any one of the listed dampproofing materials or any one of the waterproofing materials listed in Section R406.2 to the exterior of the wall.

Revise as follows:

R406.2 Concrete and masonry foundation waterproofing. In areas where a high water table or other severe soil-water conditions are known to exist, exterior foundation walls that retain earth and enclose interior spaces and floors below grade shall be waterproofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished grade. Walls shall be waterproofed in accordance with one of the following:

1. Two-ply hot-mopped felts.
2. Fifty-five-pound (25 kg) roll roofing.
3. Six-mil (0.15 mm) polyvinyl chloride.
4. Six-mil (0.15 mm) polyethylene.
5. Forty-mil (1 mm) polymer-modified asphalt.
6. Sixty-mil (1.5 mm) flexible polymer cement.
7. One-eighth-inch (3 mm) cement-based, fiber-reinforced, waterproof coating.
8. Sixty-mil (1.5 mm) solvent-free liquid-applied synthetic rubber.

All joints in membrane waterproofing shall be lapped and sealed with an adhesive compatible with the membrane.

Exception: Organic-solvent-based products such as hydrocarbons, chlorinated hydrocarbons, ketones and esters shall not be used for ICF walls with expanded polystyrene form material. Use of plastic roofing cements, acrylic coatings, latex coatings, mortars and pargings to seal ICF...
walls is permitted. Cold-setting asphalt or hot asphalt shall conform to Type C of ASTM D449. Hot asphalt shall be applied at a temperature of less than 200°F (93°C).

2. In areas where insulation is installed on the interior side of a foundation wall that extends more than 36 inches (914 mm) below the adjacent exterior ground level, a drainage layer shall be installed adjacent to the exterior surface of the foundation wall in accordance with one of the following:

2.1. A drainage layer of not less than 4 inches (102 mm) of free draining granular material.

2.2. A drainage layer that provides equivalent performance to not less than 4 inches (102 mm) of free draining granular material.

**Reason:** Objective: Reduce risk for interior basement insulation.

This code change reduces risk associated with interior insulation strategies in basement foundations. Basement water leakage occurs in 1 in 10 basements. Interior insulation reduces the ability to identify leakage early prior to significant damage occurring.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

This code change provides additional options for foundation waterproofing and dampproofing.
SECTION R408
UNDER-FLOOR SPACE

Revise as follows:

R408.1 Ventilation. Moisture Control. The under-floor space between the bottom of the floor joists and the earth under any building (except space occupied by a basement) shall have ventilation openings through foundation walls or exterior walls. The minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m$^2$) for each 150 square feet (14 m$^2$) of under-floor space area, unless the ground surface is covered by a Class 1 vapor retarder material. Where a Class 1 vapor retarder material is used, the minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m$^2$) for each 1,500 square feet (140 m$^2$) of under-floor space area. One such ventilating opening shall be within 3 feet (914 mm) of each corner of the building, comply with Section R408.2 or Section R408.3.

R408.2 Openings for under-floor ventilation. Ventilation openings through foundation or exterior walls surrounding the under-floor space shall be provided in accordance with this section. The minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m$^2$) for each 150 square feet (14 m$^2$) of under-floor area. One ventilation opening shall be within 3 feet (915 mm) of each external corner of the building under-floor space. Ventilation openings shall be covered for their height and width with any of the following materials provided that the least dimension of the covering shall not exceed 1/4 inch (6.4 mm), and operational louvers are permitted:

1. Perforated sheet metal plates not less than 0.070 inch (1.8 mm) thick.
2. Expanded sheet metal plates not less than 0.047 inch (1.2 mm) thick.
3. Cast-iron grill or grating.
4. Extruded load-bearing brick vents.
5. Hardware cloth of 0.035 inch (0.89 mm) wire or heavier.
6. Corrosion-resistant wire mesh, with the least dimension being 1/8 inch (3.2 mm) thick.

Exception Exceptions:

1. The total area of ventilation openings shall be permitted to be reduced to 1/1,500 of the under-floor area where the ground surface is covered with an approved Class I vapor retarder material and the required openings are placed to provide cross ventilation of the space. The installation of operable louvers shall not be prohibited.
2. Where the ground surface is covered with an approved Class I vapor retarder material, ventilation openings are not required to be within 3 feet (915 mm) of each external corner of the under-floor space provided the openings are placed to provide cross ventilation of the space.

R408.3 Unvented crawl space. Ventilation openings in For unvented under-floor spaces specified in Sections R408.1 and R408.2 shall not be required where the following items are provided:

1. Exposed earth shall be covered with a continuous Class I vapor retarder. Joints of the vapor retarder shall overlap by 6 inches (152 mm) and shall be sealed or taped. The edges of the
vapor retarder shall extend not less than 6 inches (152 mm) up the stem wall and shall be attached and sealed to the stem wall or insulation.

2. One of the following shall be provided for the under-floor space:

2.1. Continuously operated mechanical exhaust ventilation at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m²) of crawl space floor area, including an air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.

2.2. Conditioned air supply sized to deliver at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m²) of under-floor area, including a return air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.

2.3. Plenum in existing structures complying with Section M1601.5, if under-floor space is used as a plenum.

2.4. Dehumidification sized to provide 70 pints (33 liters) of moisture removal per day for every 1,000 square feet (93 m²) of crawl space floor area.

Reason: Section R408 was the subject of numerous code changes which resulted in R408.1 and R408.2 being essentially the same code section. R408.1 provides for the 1/1500 vent area provision in the body of the code section and R408.2 provides it in an exception. R408.2 provides for the screening of the openings and R408.1 does not. The provisions in the two sections should be combined into one section. This change accomplishes that and better formats the section for the two methods of treating under-floor spaces: vented and ventless. The code change also addresses some confusion with regards to placement of the vents. R408.1 states to place the vents 3 feet from building corners. The exception to R408.2 allows the vents to be placed to provide cross ventilation, not 3 feet from each corner, when the vapor retarder is used, which was the intent per code change G107.99. When vents are required 3 feet from each corner the current text states corner of the building. The provision for vent placement has been corrected to require the vents 3 feet from the exterior corners of the under-floor space because the current text is confusing to apply when the entire footprint of the dwelling is not on a crawls space.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change is not changing the intent, it is a clarification.
2018 International Residential Code

SECTION R408
UNDER-FLOOR SPACE

Revise as follows:

R408.3 Unvented crawl space. Ventilation openings in under-floor spaces specified in Sections R408.1 and R408.2 shall not be required where the following items are provided:

1. Exposed earth is covered with a continuous Class I vapor retarder. Joints of the vapor retarder shall overlap by 6 inches (152 mm) and shall be sealed or taped. The edges of the vapor retarder shall extend not less than 6 inches (152 mm) up the stem wall and shall be attached and sealed to the stem wall or insulation.

2. One of the following is provided for the under-floor space:
   2.1. Continuously operated mechanical exhaust ventilation at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m$^2$) of crawl space floor area, including an air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.
   2.2. Conditioned air supply sized to deliver at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m$^2$) of under-floor area, including a return air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.
   2.3. Plenum in existing structures complying with Section M1601.5, if under-floor space is used as a plenum.
   2.4. Dehumidification sized to provide 70 pints (33 liters) of moisture removal per day for every 1,000 square feet (93 m$^2$) of crawl space floor area, in accordance with the manufacturer's specifications.

Reason: Objective: Address dehumidifier sizing
Rating standards for moisture removal per day are changing (DOE) and moisture performance curves differ for different installations and entering air conditions from manufacturer to manufacturer.

Additionally, requirements may vary from climate to climate. Manufacturers update their sizing charts on a regular basis to take these factors into account.

Cost Impact: The code change proposal will decrease the cost of construction
Need for moisture removal is changing.
R408.8 Under-floor vapor retarder. In Climate Zones 1A, 2A, and 3A below the warm-humid line, a continuous Class I or II vapor retarder shall be provided on the exposed face of air permeable insulation installed between the floor joists and exposed to the grade in the under-floor space. The vapor retarder shall have a maximum water vapor permeance of 1.5 perms when tested in accordance with Procedure B of ASTM E96.

Exception: The vapor retarder shall not be required in unvented crawl spaces constructed in accordance with Section R408.3.

Reason: The purpose of this code change is to address issues that have been observed with moisture accumulation in floors above vented and open crawl spaces in hot-humid climates. Water vapor migrating from under-floor spaces in hot-humid climates such as vented crawlspace or open foundation systems towards cooler and drier indoor spaces is causing mold, mildew, and decay within floor assemblies, especially where an impermeable floor covering or underlayment is used, as moisture can get trapped within the wood subfloor and condense. Such moisture problems have occurred even where crawl spaces are constructed in accordance with the IRC, including the appropriate size and location of ventilation openings and use of Class I vapor retarders on the ground.

This change will require a Class I or Class II vapor retarder between the exposed face of air-permeable insulation materials installed between the floor framing over the crawl space and the under-floor grade. The vapor retarder can be a separate layer of material such as a 6 mil polyethylene sheet, applied over permeable or semi-permeable insulation, or incorporated as part of the insulation, such as a foil facing on fiberglass batts or polyisocyanurate rigid foam, or polypropylene-faced XPS.

An exception is provided for unvented crawl spaces (also referred to as sealed, closed or conditioned crawl spaces) constructed per the IRC. In unvented crawl spaces, mechanical exhaust ventilation, supply ventilation, or dehumidification is provided for the under-floor space to control moisture.

Cost Impact: The code change proposal will increase the cost of construction

The code change will increase cost where a sheet polyethylene vapor retarder, foil-faced rigid or batt insulation, or other materials meeting the properties of a Class I or II vapor retarder would now be required. The additional material cost for 6 mil polyethylene sheet is about 6 to 10 cents per square foot. The additional material cost for foil-faced batt insulation is about 15 to 30 cents per square foot.
**2018 International Residential Code**

Revise as follows:

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Tabulated values are for clear-span roof supported solely by exterior bearing walls.

b. Spans are based on No. 2 Grade lumber of Douglas fir-larch, Southern pine, hem-fir, and spruce-pine-fir for repetitive (three or more) members. No. 1 or better shall be used for Southern pine.

c. Ratio of backspan to cantilever span shall be not less than 3:1.

d. Connections capable of resisting the indicated uplift force shall be provided at the backspan support.

e. Uplift force is for a backspan to cantilever span ratio of 3:1. Tabulated uplift values are permitted to be reduced by multiplying by a factor equal to 3 divided by the actual backspan ratio provided (3/backspan ratio).

f. See Section R301.2.2.6, Item 1, for additional limitations on cantilevered floor joists for detached one- and two-family dwellings in Seismic Design Category D, D, or D and townhouses in Seismic Design Category C, D, D, or D.

g. A full-depth rim joist shall be provided at the unsupported end of the cantilever joists. Solid...
blocking shall be provided at the supported end. Where the cantilever length is 24 inches or less and the building is assigned to Seismic Design Category A, B or C, solid blocking at the support for the cantilever shall not be required.

h. Linear interpolation shall be permitted for building widths and ground snow loads other than shown.

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa.

a. Spans are based on No. 2 Grade lumber of Douglas fir-larch, Southern pine, hem-fir, and spruce-pine-fir for repetitive (three or more) members. No. 1 or better shall be used for Southern pine.

b. Ratio of backspan to cantilever span shall be not less than 2:1.

c. Connections capable of resisting the indicated uplift force shall be provided at the backspan support.

d. Uplift force is for a backspan to cantilever span ratio of 2:1. Tabulated uplift values are permitted to be reduced by multiplying by a factor equal to 2 divided by the actual backspan ratio provided (2/backspan ratio).

e. A full-depth rim joist shall be provided at the unsupported end of the cantilever joists. Solid blocking shall be provided at the supported end. Where the cantilever length is 24 inches or less and the building is assigned to Seismic Design Category A, B or C, solid blocking at the support for the cantilever shall not be required.

f. Linear interpolation shall be permitted for ground snow loads other than shown.

**Reason:** In 2012, full-scale testing of visually-graded southern pine lumber was underway and preliminary results indicated that some changes to visually-graded southern pine design values would be required. Unfortunately, the testing and certification of design values were not going to be completed in time to submit new design tables to the 2015 IRC, if required. Several 2012 IRC tables, which had been based on minimum design values for No. 2 grade Hem-Fir or SPF lumber, also applied to No. 2 grade southern pine. As an interim recommendation until new design values could be certified, a sentence was added to those tables restricting the applicability to No.1 grade or better southern pine lumber. Since that time, new design values for southern pine have been certified. Bending design values for No. 2 grade southern pine are slightly less than No. 2 grade Hem-Fir lumber, but Modulus of Elasticity (MOE) and shear design values are higher than those for Hem-Fir. Analysis of the tabulated cantilever spans in Tables R502.3.3(1) and R502.3.3(2) has confirmed that the spans were deflection-controlled based on the MOE of No. 2 grade of Hem-Fir lumber. Since No. 2 grade southern
pine lumber has a higher MOE value than No. 2 grade Hem-Fir lumber, there is no need for the added sentence at the end of footnote “b” in Table R502.3.3(1) and at the end of footnote “a” in Table R502.3.3(2) restricting the applicability to No. 1 or better southern pine lumber.

**Cost Impact:** The code change proposal will decrease the cost of construction
Cost of construction will usually decrease if No. 2 grade Southern Pine is used instead of No. 1 grade as a result of the current restriction on No. 2 grade being removed.

Proposal # 4279

RB179-19
2018 International Residential Code

Add new text as follows:

**R505.1.1.1 Alternate Applications** Cold-formed steel floor framing for buildings exceeding the applicability limits of Section R505.1.1 are permitted to be designed and constructed in accordance with AISI S230, subject to the limits therein.

**R603.1.1.1 Alternate Applications.** Cold-formed steel wall framing for buildings exceeding the applicability limits of Section R603.1.1 are permitted to be designed and constructed in accordance with AISI S230, subject to the limits therein.

**R804.1.1.1 Alternate Applications** Cold-formed steel roof and ceiling framing for buildings exceeding the applicability limits of Section R804.1.1 are permitted to be designed and constructed in accordance with AISI S230, subject to the limits therein.

**Reason:** The intent of this code change proposal is to direct the user AISI S230 – *Standard for Cold-Formed Steel Framing - Prescriptive Method for One- and Two-Family Dwellings* (AISI S230-18) for cold-formed steel framed buildings and structures exceeding the building size limits of 60 feet long and 40 feet wide as prescribed in the *Applicability Limits* of each section (R603.1.1, R505.1.1, R804.1.1).

The 2018 edition of AISI S230 removed the building dimension limitations (in plan dimension) listed in Table A1-1 and moved to an interior braced wall line approach. Rather than significantly expanding the cold-formed steel framing provisions within the IRC, AISI is proposing to direct the user to AISI S230-18 for conditions utilizing interior braced wall lines. While AISI S230 is already permitted as an alternate standard via Section R301.1.1 – *Alternate Provisions*, the proposed language is intended to provide the user with knowledge that additional prescriptive provisions for expanded conditions are available in the AISI S230 standard. The approach proposed in this code change coincides with the approach of AISI over the past few cycles to streamline the cold-formed steel provisions within the IRC.

There is a concurrent code change proposal to update Chapter 44 to AISI S230-18. A draft version of AISI S230-18 is currently available for review at www.aisistandards.org. AISI anticipates the final published edition of AISI S230-18 will be available at the same website free of charge by March 1, 2019.

**Bibliography:** AISI (2018), *Standard for Cold-Formed Steel Framing - Prescriptive Method for One- and Two-Family Dwellings*, ANSI/AISI S230-18, American Iron and Steel Institute, Washington D.C.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal does not make technical changes to the provisions of the IRC.
2018 International Residential Code

Revise as follows:

R505.1.2 In-line framing. Where supported by cold-formed steel-framed walls in accordance with Section R603, cold-formed steel floor framing shall be constructed with floor joists located in-line with load-bearing studs located below the joists in accordance with the tolerances specified in AISI S240 Section B1.2.3. Figure R505.1.2 and the tolerances specified as follows:

1. The maximum tolerance shall be \( \frac{3}{8} \) inch (19.1 mm) between the centerline of the horizontal framing member and the centerline of the vertical framing member.

2. Where the centerline of the horizontal framing member and bearing stiffener are located to one side of the centerline of the vertical framing member, the maximum tolerance shall be \( \frac{1}{4} \) inch (3 mm) between the web of the horizontal framing member and the edge of the vertical framing member.

Delete without substitution:
Revise as follows:

**R505.1.3 Floor trusses.** Cold-formed steel trusses shall be designed, braced and installed in accordance with AISI S230 Section D8, S240. In the absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practices, such as the SBCA Cold-Formed Steel Building Component Safety Information (CFSBCSI), Guide to Good Practice for Handling, Installing & Bracing of Cold-Formed Steel Trusses. Truss members shall not be notched, cut or altered in any manner without an approved design.

**R505.2 Structural framing.** Load-bearing cold-formed steel floor framing members shall be in accordance with this section.

Revise as follows:

**R505.2.1 Material.** Load-bearing cold-formed steel framing members shall be cold formed to shape from structural quality sheet steel complying with the requirements of ASTM A1003: Structural Grades 33 Type H and 50 Type H. AISI S240 Section A3.

**R505.2.2 Corrosion protection.** Load-bearing cold-formed steel framing shall have a metallic coating complying with AISI S240 Section A4, ASTM A1003 and one of the following:

1. Not less than G 60 in accordance with ASTM A653.
2. Not less than AZ 50 in accordance with ASTM A792.

**R505.2.3 Dimension, thickness and material grade.** Load-bearing cold-formed steel floor framing members shall comply with Figure R505.2.3(1) and with the dimensional and thickness requirements specified in Table R505.2.3. Additionally, all C-shaped sections shall have a minimum flange width of 1.625 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be $\frac{1}{16}$ inch (1.7 mm).
Track sections shall comply with Figure R505.2.3(2) and shall have a minimum flange width of 1 4/16-inch (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified. AISI S230 Section A4.3 and material grade requirements as specified in AISI S230 Section A4.4.

a. The member designation is defined by the first number representing the member depth in 0.01 inch, the letter “S” representing a stud or joist member, the second number representing the flange width in 0.01 inch, and the letter “t” shall be a number representing the minimum base metal thickness in mils.
FIGURE R505.2.3(1)
C-SHAPED-SECTION
Revise as follows:

**R505.2.4 Identification.** Load-bearing cold-formed steel framing members shall meet the product identification requirements of AISI S240 Section A5.5, have a legible label, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer’s identification.
2. Minimum base steel thickness in inches (mm).
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

**R505.2.6 Web holes, web hole reinforcing and web hole patching.** Web holes, web hole reinforcing, and web hole patching shall be in accordance with this section. In floor framing members shall comply with the conditions as prescribed in AISI S230 Section A4.5. Web holes not in conformance with the conditions as prescribed in AISI S230 Section A4.5 shall be reinforced in accordance with the provisions of AISI S230 Section A4.6 or patched in accordance with the provisions of AISI S230 Section A4.7.

Delete without substitution:

**R505.2.6.1 Web holes.** Web holes in floor joists shall comply with all of the following conditions:

1. Holes shall conform to Figure R505.2.6.1.
2. Holes shall be permitted only along the centerline of the web of the framing member.
3. Holes shall have a center-to-center spacing of not less than 24 inches (610 mm).
4. Holes shall have a web hole width not greater than 0.5 times the member depth, or 2\(\frac{1}{2}\) inches (64.5 mm). 
5. Holes shall have a web hole length not exceeding 4\(\frac{3}{4}\) inches (114 mm).
6. Holes shall have a minimum distance between the edge of the bearing surface and the edge of the web hole of not less than 10 inches (254 mm).

Framing members with web holes not conforming to these requirements shall be reinforced in accordance with Section R505.2.6.2, patched in accordance with Section R505.2.6.3 or designed in accordance with accepted engineering practices.
R505.2.6.2 Web hole reinforcing. Reinforcement of web holes in floor joists not conforming to the requirements of Section R505.2.6.1 shall be permitted if the hole is located fully within the center 40 percent of the span and the depth and length of the hole does not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shaped section with a hole that does not exceed the web hole size limitations of Section R505.2.6.1 for the member being reinforced. The steel reinforcing shall be not thinner than the thickness of the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of \(1/2\) inch (12.7 mm).

R505.2.6.3 Hole patching. Patching of web holes in floor joists not conforming to the requirements in Section R505.2.6.1 shall be permitted in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practices where web holes exceed the following size limits:
   1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.
   1.2. The length of the hole, measured along the web, exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R505.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R505.2.6.3. The steel patch shall, as a minimum, be of the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of \(1/2\) inch (12.7 mm).
FIGURE R505.2.6.3

IN-LINE FRAMING

**R603.2 Structural framing.** Load-bearing cold-formed steel wall framing members shall be in accordance with this section.

Revise as follows:

**R603.2.1 Material.** Load-bearing cold-formed steel framing members shall be cold formed to shape from structural-quality sheet steel complying with the requirements of ASTM A1003: Structural Grades 33 Type H and 50 Type H. AISI 240 Section A3.

**R603.2.2 Corrosion protection.** Load-bearing cold-formed steel framing shall have a metallic protective coating complying with AISI S240 Section A4, ASTM A1003 and one of the following:

1. Not less than G 60 in accordance with ASTM A653.
2. Not less than AZ 50 in accordance with ASTM A792.

**R603.2.3 Dimension, thickness and material grade.** Load-bearing cold-formed steel wall framing members shall comply with Figure R603.2.3(1) and with the dimensional and thickness requirements specified in Table R603.2.3. Additionally, C-shaped sections shall have a minimum flange width of 1 5/8 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be 1/8 inch (12.7 mm). Track sections shall comply with Figure R603.2.3(2) and shall have a minimum flange width of 1 3/4 inches (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified. AISI S230 Section A4.3 and material grade requirements as specified in AISI S230 Section A4.4.

3. Holes shall have a center-to-center spacing of not less than 24 inches (610 mm).
4. Holes shall have a web hole width not greater than 0.5 times the member depth, or 1 1/8 inches (38 mm).
5. Holes shall have a web hole length not exceeding 4 1/2 inches (114 mm).
6. Holes shall have a minimum distance between the edge of the bearing surface and the edge of the web hole of not less than 10 inches (254 mm).

Framing members with web holes not conforming to the above requirements shall be reinforced in accordance with Section R603.2.6.2, patched in accordance with Section R603.2.6.3 or designed in accordance with accepted engineering practice.
For SI: 1 inch = 25.4 mm.

**FIGURE R603.2.6.1 WALL STUD WEB HOLES**

**R603.2.6.2 Web hole reinforcing.** Web holes in gable endwall studs not conforming to the requirements of Section R603.2.6.1 shall be permitted to be reinforced if the hole is located fully within the center 40 percent of the span and the depth and length of the hole does not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shaped section with a hole that does not exceed the web hole size limitations of Section R603.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of 1/2 inch (12.7 mm).

**R603.2.6.3 Hole patching.** Web holes in wall studs and other structural members not conforming to the requirements in Section R603.2.6.1 shall be permitted to be patched in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practice where web holes exceed the following size limits:
   1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.
   1.2. The length of the hole measured along the web exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R603.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R603.2.6.3. The steel patch shall, as a minimum, be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with a minimum edge distance of 1/2 inch (12.7 mm).
Revise as follows:

**R804.1.2 In-line framing.** Cold-formed steel roof framing constructed in accordance with Section R804 shall be located in line with load-bearing studs in accordance with the tolerances specified in AISI S240 Section B1.2.3. Figure R804.1.2 and the tolerances specified as follows:

1. The maximum tolerance shall be \( \frac{3}{8} \) inch (19.1 mm) between the centerline of the horizontal framing member and the centerline of the vertical framing member.
2. Where the centerline of the horizontal framing member and bearing stiffener are located to one side of the centerline of the vertical framing member, the maximum tolerance shall be \( \frac{1}{8} \) inch (3.2 mm) between the web of the horizontal framing member and the edge of the vertical framing member.

Delete without substitution:
For SI: 1 inch = 25.4 mm.

FIGURE R804.1.2
IN-LINE FRAMING

R804.2 Structural framing. Load-bearing, cold-formed steel roof framing members shall be in accordance with this section.

Revise as follows:

R804.2.1 Material. Load-bearing, cold-formed steel framing members shall be cold formed to shape from structural quality sheet steel complying with the requirements of ASTM A1003, Structural Grades 33 Type H and 50 Type H, AISI S240 Section A3.

R804.2.2 Corrosion protection. Load-bearing, cold-formed steel framing shall have a metallic protective coating complying with AISI S240 Section A4, ASTM A1003 and one of the following:

1. Not less than G 60 in accordance with ASTM A653.
2. Not less than AZ 50 in accordance with ASTM A792.

R804.2.3 Dimension, thickness and material grade. Load-bearing, cold-formed steel roof framing members shall comply with Figure R804.2.3(1) and with the dimensional and thickness requirements specified in Table R804.2.3. Additionally, C-shaped sections shall have a minimum flange width of 1.625 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be \( \frac{1}{4} \) inch (12.7 mm). Tracks shall comply with Figure R804.2.3(2) and shall have a minimum flange width of \( \frac{7}{16} \) inches (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified. AISI S230 Section A4.3 and material grade requirements as specified in AISI S230 Section A4.4.

FIGURE R804.2.3(1)
C-SHAPED-SECTION
Revise as follows:

**R804.2.4 Identification.** Load-bearing, cold-formed steel framing members shall meet the product identification requirements of AISI S240 Section A5.5, have a legible label, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer's identification.
2. Minimum base steel thickness in inches (mm).
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

**R804.2.6 Web holes, web hole reinforcing and web hole patching.** Web holes, web hole reinforcing and web hole patching shall be in accordance with this section. Web holes in roof or ceiling joists shall comply with the conditions as prescribed in AISI S230 Section A4.5. Web holes not in conformance with the conditions of AISI S230 Section A4.5 shall be reinforced in accordance with the provisions of AISI S230 Section A4.6 or patched in accordance with the provisions of AISI S230 Section A4.7.

Delete without substitution:

**R804.2.6.1 Web holes.** Web holes in roof framing members shall comply with all of the following conditions:

1. Holes shall conform to Figure R804.2.6.1.
2. Holes shall be permitted only along the centerline of the web of the framing member.
3. Center-to-center spacing of holes shall be not less than 24 inches (610 mm).
4. The web-hole width shall be not greater than one-half the member depth, or $2\frac{1}{4}$ inches (64 mm).
5. Holes shall have a web-hole length not exceeding $4\frac{1}{4}$ inches (114 mm).
6. The minimum distance between the edge of the bearing surface and the edge of the web hole shall be not less than 10 inches (254 mm).

Framing members with web holes not conforming to Items 1 though 6 shall be reinforced in accordance with Section R804.2.6.2, patched in accordance with Section R804.2.6.3 or designed in accordance with accepted engineering practices.
For SI: 1 inch = 25.4 mm.

R804.2.6.2 Web hole reinforcing. Reinforcement of web holes in ceiling joists not conforming to the requirements of Section R804.2.6.1 shall be permitted if the hole is located fully within the center 40 percent of the span and the depth and length of the hole do not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shaped section with a hole that does not exceed the web hole size limitations of Section R804.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not greater than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of \( \frac{1}{2} \) inch (12.7 mm).

R804.2.6.3 Hole patching. Patching of web holes in roof framing members not conforming to the requirements in Section R804.2.6.1 shall be permitted in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practices where web holes exceed either of the following size limits:

   1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.
   1.2. The length of the hole measured along the web, exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R804.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R804.2.6.3. The steel patch shall, as a minimum, be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not greater than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of \( \frac{1}{2} \) inch (12.7 mm).
For SI: 1 inch = 25.4 mm.

FIGURE R804.2.6.3 ROOF FRAMING MEMBER WEB HOLE PATCH

Revise as follows:

**R804.3.6 Roof trusses.** Cold-formed steel trusses shall be designed and installed in accordance with AISI S240. In the absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practices, such as the SBCA Cold-Formed Steel Building Component Safety Information (CFSBCSI) Guide to Good Practice for Handling, Installing & Bracing of Cold-Formed Steel Trusses – S230 Section F6. Trusses shall be connected to the top track of the load-bearing wall in accordance with Table R804.3, either with the required number of No. 10 screws applied through the flange of the truss or by using a 54-mil (1.37 mm) clip angle with the required number of No. 10 screws in each leg.

**Reason:** This proposal is the continuation of efforts by the American Iron and Steel Institute (AISI) over the past few ICC code cycles to streamline and consolidate cold-formed steel framing provisions within the International Residential Code (IRC). The intent of this proposal is to direct the user to AISI S230 – Standard for Cold-Formed Steel Framing - Prescriptive Method for One- and Two-Family Dwellings (AISI S230-18) and AISI S240 - North American Standard for Cold-Formed Steel Structural Framing (AISI S240-15) for cold-formed steel framing provisions related to specific material and member requirements. The provisions in this proposal identified to be replaced with reference to AISI standards are repeated verbatim in all cold-formed steel framing sections in the IRC (Sections 505, 603, and 804). In addition, all of the provisions proposed to be replaced are identical to those being referenced in AISI standards. Therefore, there are no technical changes being proposed through this code change proposal. To aid the committee, an AISI-IRC cross reference document has been attached to this proposal. The cross reference document displays all sections from AISI standards being referenced to the corresponding IRC sections (in the order as they appear in the code change proposal).

There is a concurrent proposal updating the reference in Chapter 44 to AISI S230-18.

AISI standards are free of charge and available for download at www.aisistandards.org.

**Bibliography:**
**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This code change does not propose any technical changes to the material requirements or framing practices for cold-formed steel framing. The intention is simply to direct the user to the appropriate AISI standard for the necessary information. All AISI standards are available free of charge at www.aisistandards.org.

Proposal # 3968

RB181-19
RB182-19

IRC: R506.1, CHAPTER 44 PTI (New)

Proponent: Amy Dowell, representing Post-Tensioning Institute (amy.dowell@post-tensioning.org); Stephen Szoke, representing American Concrete Institute (steve.szoke@concrete.org)

2018 International Residential Code

Revise as follows:

R506.1 General. Concrete slab-on-ground floors, other than post-tensioned slab-on-ground floors, shall be designed and constructed in accordance with the provisions of this section or ACI 332. Floors—Such floors shall be a minimum 3½ inches (89 mm) thick (for expansive soils, see Section R403.1.8). Post-tensioned concrete slabs-on-ground floors placed on expansive or stable soils shall be designed and constructed in accordance with PTI DC—10.5. The specified compressive strength of concrete shall be as set forth in Section R402.2.

Add new text as follows:

Add new standard(s) as follows:

DC—10.5-12: Standard Requirements for Design and Analysis of Shallow Concrete Foundations on Expansive and Stable Soils

Reason: There are currently no provisions for designing post-tensioned slabs on expansive or stable soils in IRC. This proposal includes a new reference to PTI standard PTI DC10.5-19, Standard Requirements for Design and Analysis of Shallow Concrete Foundations on Expansive and Stable Soils. Post-tensioned slabs are commonly used on stable soils for crack control as well as reduced slab thickness and nonprestressed steel use. This reduction in material use typically offsets the cost of the post-tensioning materials and labor.

Additional documentation can be viewed at http://ww2.post-tensioning.org/PDF_FILES/190102-DC10.5-Expansive and Stable Soils-Public Review.pdf.

Bibliography: .

Cost Impact: The code change proposal will not increase or decrease the cost of construction Post-tensioned slabs are commonly used on expansive and stable soils for crack control as well as reduced slab thickness and nonprestressed steel use. This reduction in material use typically offsets the cost of the post-tensioning materials and labor.

Staff Analysis: The referenced standard, PTI-DC-10.5-12, is currently referenced in other 2018 I-codes.
RB183-19

IRC®: R506.2.3, ASTM Chapter 44 (New)

Proponent: Terry Kozlowski, representing Southern Nevada Chapter; Valarie Evans, representing Southern Nevada Chapter; Amanda Moss, representing SN-ICC Member; Cassidy Wilson, representing SN-ICC Member; Nenad Mirkovic, representing City of Las Vegas

2018 International Residential Code

Revise as follows:

R506.2.3 Vapor retarder. A 6-mil-10-mil (0.006-0.010 inch; 152 µm-0.254 mm) polyethylene or approved vapor retarder conforming to ASTM E 1745 Class A requirements with joints lapped not less than 6 inches (152 mm) shall be placed between the concrete floor slab and the base course or the prepared subgrade where a base course does not exist.

Exception: The vapor retarder is not required for the following:

1. Garages, utility buildings and other unheated accessory structures.
2. For unheated storage rooms having an area of less than 70 square feet (6.5 m²) and carports.
3. Driveways, walks, patios and other flatwork not likely to be enclosed and heated at a later date.
4. Where approved by the building official, based on local site conditions.

Add new text as follows:

ASTM

E1745-17: Standard Specification for Plastic Water Vapor Retarders Used in Contact with Soil or Granular Fill under Concrete Slabs

Reason: By coordinating the requirements for the vapor retarder with the American Concrete Institute (ACI) recommendations, this proposal will promote consistency across codes and standards for various moisture conditions.

Bibliography: ACI 302.2R Section 9.3:
“...ACI 302.1R recommends a minimum 10 mil (0.25 mm) vapor retarder thickness when the retarder is protected with a granular fill. When the vapor retarder is not protected by a fill, some specifiers require a 15 mil (0.38 mm) thickness or greater...”

Cost Impact: The code change proposal will increase the cost of construction
This proposal will increase the cost of construction for an average 2,200 square foot single-family dwelling by an estimated $28.60, based on cost analysis in current market conditions.

Staff Analysis: A review of the standard proposed for inclusion in the code, ASTM E1745-17, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proponent: Deck Code Coalition, Charles Bajnai (chair), North American Deck and Railing Assoc (NADRA), Retired from Chesterfield County, VA, representing Deck Code Coalition (csbajnai@gmail.com)

2018 International Residential Code

Revise as follows:

R507.1 Decks. Wood-framed decks shall be in accordance with this section. Decks shall be designed for the live load required in Section R301.5 or the ground snow load indicated in Table R301.2(1), whichever is greater. For decks using materials and conditions not prescribed in this section, refer to Section R301.
For SI: 1 inch = 25.4 mm, 1 square foot = 0.0929 m², 1 pound per square foot = 0.0479 kPa.

a. Interpolation permitted, extrapolation not permitted.
b. Based on highest load case: Dead + Live or Dead + Snow.
c. Assumes minimum square footing to be 12 inches x 12 inches x 6 inches for 4 x 4 post. Footing dimensions shall allow complete bearing of the post.
d. If the support is a brick or CMU pier, the footing shall have a minimum 2-inch projection on all sides.
e. Area, in square feet, of deck surface supported by post and footings.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

---

**R507.4 Deck posts.** For single-level wood-framed decks with beams sized in accordance with Table R507.5, wood deck post size shall be in accordance with Table R507.4.

Delete and substitute as follows:

<table>
<thead>
<tr>
<th>DECK POST SIZE</th>
<th>MAXIMUM HEIGHT(a, b) (feet-inches)</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

---

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

---

a. Measured to the underside of the beam.
b. Based on 40 psf live load.
c. The maximum permitted height is 8 feet for one-ply and two-ply beams. The maximum permitted height for three-ply beams on post cap is 6 feet 9 inches.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa., NP = Not Permitted

a. Measured from the underside of the beam to top of footing or pier.

b. 10 psf dead load. Snow load not assumed to be concurrent with live load.

c. No. 2 grade, wet service factor included.

d. Notched deck posts shall be sized to accommodate beam size per in accordance with Section R507.5.2

e. Includes incising factor.

f. Incising factor not included.

g. Area, in square feet, of deck surface supported by post and footings.

h. Interpolation permitted. Extrapolation not permitted.

Revise as follows:

R507.5 Deck Beams. Maximum allowable spans for wood deck beams, as shown in Figure R507.5, shall be in accordance with Table R507.5—Tables R507.5(1) through R507(4). Beam plies shall be fastened with two rows of 10d (3-inch × 0.128-inch) nails minimum at 16 inches (406 mm) on center along each edge. Beams shall be permitted to cantilever at each end up to one-fourth of the allowable beam span. Deck beams of other materials shall be permitted where designed in accordance with accepted engineering practices.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, 1 pound = 0.454 kg.

b. Beams supporting a single span of joists with or without cantilever.

c. a. Ground snow load, live load = 40 psf, dead Dead load = 10 psf, L/Δ = 360 at main span, L/Δ = 180 at cantilever with a 220 pound point load applied at the end. Snow load not assumed to be concurrent with live load.

b. Beams supporting deck joists from one side only.

d. c. No. 2 grade, wet service factor included.

e. d. Beam depth shall be equal to or greater than or equal to depth of joists with the depth intersecting joist for a flush beam condition connection.

f. g. Beam cantilevers are limited to the adjacent beam’s span divided by 4.

g. e. Includes incising factor.

h. f. Northern species. Incising factor not included.

i. Deck joist span as shown in Figure R507.5

g. Includes incising factor

h. Incising factor not included.

i. Deck joist span as shown in Figure R507.5

Revise as follows:

R507.6 Deck joists. Maximum allowable spans for wood deck joists, as shown in Figure R507.6, shall be in accordance with Table R507.6. The maximum joist spacing shall be limited by the decking materials in accordance with Table R507.7. The maximum joist cantilever shall be limited to one-fourth of the joist span or the maximum cantilever length specified in Table R507.6, whichever is less.

</table>

The table above represents the load capacity and ground characteristics for various materials, including Southern Pine, Douglas fir-larch, Hem-fir, Spruce-pine-fir, Redwood, Western Cedars, Ponderosa Pine, and Red Pine, under different load conditions and ground types. The load capacities are indicated in terms of force per unit area or section, with values ranging from 50 to 80 in increments of 10, with corresponding forces of 70, 60, 50, 40, 30, 20, and 10. The ground types include Load and Ground, each with specific conditions and capacities. The table highlights the force required for each type and condition, indicating the necessary strength and capacity for structural and construction applications.
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, 1 pound = 0.454 kg. NP = Not Permitted

a. Dead load = 10 psf. Snow load not assumed to be concurrent with live load.

b. No. 2 grade, wet service factor included.

c. L/Δ = 360 at main span.

d. L/Δ = 180 at cantilever with 220-pound point load applied to end.

e. Includes incising factor.

f. Incising factor not included.

g. Interpolation permitted. Extrapolation is not permitted.

</tbody>
</table>
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Interpolation permitted. Extrapolation is not permitted.

b. Ledgers shall be flashed in accordance with Section R703.4 to prevent water from contacting the house band joist.

c. Dead Load = 10 psf. Snow load shall not be assumed to act concurrently with live load.

d. The tip of the lag screw shall fully extend beyond the inside face of the band joist.

e. Sheathing shall be wood structural panel or solid sawn lumber.

f. Sheathing shall be permitted to be wood structural panel, gypsum board, fiberboard, lumber or foam sheathing. Up to $\frac{1}{2}$-inch thickness of stacked washers shall be permitted to substitute for up to $\frac{1}{2}$ inch of allowable sheathing thickness where combined with wood structural panel or lumber sheathing.

**Reason:** From roughly scanning Figure R301.2(6) Ground Snow Loads, it appears that as much as ten percent of the country lives in areas where the ground snow load exceeds the live load in Table R301.5. The Deck Code Coalition proposes to prescriptively offer the people in these areas with revised tables. The IRC’s prescriptive deck provisions currently only include a 40 psf live load and 10 psf dead load. This proposal is to widen the deck provisions to include up to 70 psf ground snow load to more closely match the scope of the IRC.

For snow loading, an increase in wood strength is accounted for the load duration per the NDS®. While the geometry of the deck and nearby structures can affect the snow loading by causing drifts or snow falling from a nearby roof, these effects are neglected just as in other IRC tables, such as roof rafters. Similarly, elevated decks would have a snow load less than the ground snow load, but this reduction is neglected for simpler tables that are easy to use.

- **Table R507.3.1 Minimum Footing Size for Decks** - currently the table includes footings from 40 to 70 psf, but limits the minimum size of footing to 12” x 12”, which is significantly oversized for small areas such as a stair landing. New rows have been added for a smaller 7” x 7” footing which is more appropriate and allows for some precast concrete solutions.

- **Table R507.4 Maximum Deck Post Height** – the table is based now on tributary area 40, 50, 60, and 70 psf loading.

- **Table R507.5(1) Maximum Deck Beam Span** was replaced with four new tables R507.5(1) – (4) to account for the 40, 50, 60, and 70 psf loading. Section R507.5.2 now includes information that was previously in a footnote.

</table>
The load from tributary areas are altered to reflect joists and beams with cantilevers.

- **Table R507.6 Maximum Deck Joist Spans** was amended to account for the 40, 50, 60, and 70 psf loading. The formatting of the table is significantly altered to clarify common confusion on allowable cantilevers. Previously, the table gave the allowable cantilever in terms of joist spacing. Since the assumed main span was the allowable span for that spacing, the maximum cantilevers sometimes became smaller as joist spacing became tighter. The new format has the cantilevers be more accurately based upon the main span. The previous table included a cantilever limit of \(\frac{1}{4}\) the main span, and this limit is preserved. Where cantilevers are not permitted, the size of lumber is too small to support that main span.

- **Table R507.9.1.3(1) Deck Ledger Connection to Band Joist** - the table is based now on tributary area 40, 50, 60, and 70 psf loading, but uses the same empirical capacities from the original table.

**Cost Impact:** The code change proposal will increase the cost of construction

In those parts of the country where the ground snow load exceeds 40 psf, it could be assumed that there would be an increased cost of construction if the local jurisdictions allowed decks to be built with a lesser live load than the ground snow load might warrant for their areas. However, by adding 50, 60, and 70 psf to the prescriptive tables, some builders may save money by eliminating the cost of engineering that might otherwise be required.

For the other ninety percent of the country, there would not be an anticipated increased cost of construction, in fact there could be a reduced cost for some situations where a smaller footing requirement may be applicable.
2018 International Residential Code

Revise as follows:

R312.1.4 Exterior plastic composite guards. Plastic composite exterior Exterior guards shall comply with the requirements of Section R317.4. [R507.10].

Add new text as follows:

R507.10 Exterior guards. Guards shall be constructed to meet the requirements of Section R301.5, R312 and this section.

R507.10.1 Support of guards. Where guards are supported on deck framing, guard loads shall be transferred to the deck framing with a continuous load path to the deck joists.

R507.10.1.1 Guards supported by side of deck framing. Where guards are connected to the interior or exterior side of a deck joist or beam, the joist or beam shall be connected to the adjacent joists to prevent rotation of the joist or beam. Connections relying only on fasteners in end grain withdrawal are not permitted.

R507.10.1.2 Guards supported on top of deck framing. Where guards are mounted on top of the decking, the guards shall be connected to the deck framing or blocking and installed in accordance with approved manufacturer’s instructions to transfer the guard loads to the adjacent joists.

R507.10.2 Wood guards. Wood posts supporting guard loads shall be a minimum 4x4. Such 4x4 wood posts supporting guard loads shall not be notched at the connection to the supporting structure.

R507.10.3 Plastic composite guards. Plastic composite guards shall comply with the provisions of Section R507.2.2.

R507.10.4 Other guards. Other approved guards shall be in accordance with manufacturer’s instructions or in accordance with accepted engineering principles.

Reason: The Deck Code Coalition submits this code change to include direction for constructing exterior guards on decks where the code is currently silent. Guards provide the first line of defense against significant falls, which can result in serious and sometimes fatal injuries. Exterior guards on decks, particularly the connection of the guard system to the deck framing, are rarely engineered and even more rarely tested in a manner that proves that they are adequate to meet the requirements of Table R301.5. Exterior guards and the framing supporting them are susceptible to deterioration, and therefore require a level of care that we think should be addressed in the code.

While the language of the proposal does not define a prescriptive detail for either guard construction or a guard connection to deck framing, the intent of the language is to guide both the builder and the building officials toward an understanding of the behavior of the guard and the structure supporting the guard. The language provides guidance for developing details that will resist the action of a guard on the deck framing when the guard is protecting an occupant from falling to a lower level. This proposal should save lives.

Cost Impact: The code change proposal will increase the cost of construction

Current building practices may not meet the requirements of Table R301.5 when typical code-required safety
factors are applied, it is reasonable to assume that there will be an increase in cost as the construction techniques and details of these elements are modified to meet the proposed language. A direct result will likely be an increase in the number of fasteners, blocking labor associated with the construction of exterior guards. For those currently construction code-compliant guards, there will be little, if any, additional costs.

For those that need to update their construction techniques and wish to do so using proprietary fasteners, the material cost increase may be approximately $20 per post, or approximately $140 for a 12 foot by 12 foot attached deck. The extra cost has to be weighed against the increased safety and potential life savings that will occur across the country over many years.
2018 International Residential Code
Revise as follows:

TABLE R507.2.3
FASTENER AND CONNECTOR SPECIFICATIONS FOR DECKSa, b

<table>
<thead>
<tr>
<th>ITEM</th>
<th>MATERIAL</th>
<th>MINIMUM FINISH/COATING</th>
<th>ALTERNATE FINISH/COATINGc</th>
</tr>
</thead>
<tbody>

<td>Hot-dipped galvanized per ASTM A153, Class D for 3/8-inch diameter and less</td>
<td>Stainless steel, silicon bronze or copper</td>
</tr>
<tr>
<td>Boltsc Lag screwsd (including nuts and washers)</td>
<td>In accordance with ASTM A307 (bolts), ASTM A563 (nuts), ASTM F844 (washers)</td>
<td>Hot-dipped galvanized per ASTM A153, Class C (Class D for 9/8-inch diameter and less) or mechanically galvanized per ASTM B695, Class 55 or 410 stainless steel</td>
<td>Stainless steel, silicon bronze or copper</td>
</tr>
<tr>
<td>Metal connectors</td>
<td>Per manufacturer’s specification</td>
<td>ASTM A653 type G185 zinc coated galvanized steel or post hot-dipped galvanized per ASTM A123 providing a minimum average coating weight of 2.0 oz./ft² (total both sides)</td>
<td>Stainless steel</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Equivalent materials, coatings and finishes shall be permitted.
b. Fasteners and connectors exposed to salt water or located within 300 feet of a salt water shoreline shall be stainless steel.
c. Holes for bolts shall be drilled a minimum 1/32 inch and a maximum 1/16 inch larger than the bolt.
d. Lag screws 1/2 inch and larger shall be predrilled to avoid wood splitting per the National Design Specification (NDS) for Wood Construction.
e. Stainless-steel-driven fasteners shall be in accordance with ASTM F1667.

Reason: Timber Rivets are not addressed in ASTM F1667
Nails are 3/8” in diameter or less. ASTM A153 calls for Class D coating (minimum 1 oz. / ft²) for this size fastener.

These changes align with the requirements of these ASTM standards.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
There will be no change in cost of construction. The proposal just clarifies the standards.

Proposal # 3866
Proponent: Deck Code Coalition, Charles Bajnai (chair), North American Deck and Railing Assoc (NADRA), Retired from Chesterfield County, VA, representing Deck Code Coalition (csbajnai@gmail.com)

2018 International Residential Code

Revise as follows:

R507.3 Footings. Decks shall be supported on concrete footings or other approved structural systems designed to accommodate all loads in accordance with Section R301. Deck footings shall be sized to carry the imposed loads from the deck structure to the ground as shown in Figure R507.3. The footing depth shall be in accordance with Section R403.1.4.

Exception:

Footings shall not be required for free decks consisting of joists directly supported on grade over their entire length.

Footings shall not be required for freestanding decks that meet all of the following criteria:

2.1. The joists bear directly on precast concrete pier blocks at grade without support by beams or posts.
2.2. The area of the deck does not exceed 200 square feet.
2.3. The walking surface is not more than 20 inches above grade at any point within 36 inches measured horizontally from the edge.

R507.3.2 Minimum depth. Deck footings shall extend below the frost line specified in Table R301.2(1) in accordance with Section R403.1.4.1. Deck footings shall be placed not less than 12 inches below the undisturbed ground surface.

Exceptions:

1. Free-standing decks that meet all of the following criteria:
   1.1. The joists bear directly on precast concrete pier blocks at grade without support by beams or posts.
   1.2. The area of the deck does not exceed 200 square feet (18.9 m²).
   1.3. The walking surface is not more than 20 inches (616 mm) above grade at any point within 36 inches (914 mm) measured horizontally from the edge.

R507.3.3 Frost protection. Where decks are attached to a frost protected structure, deck footings shall be protected from frost by one or more of the following methods:

1. By extending below the frost line specified in Table R301.2(1).
2. By erecting on solid rock.
3. Other approved methods of frost protection.

Revise as follows:

Add new text as follows:
R403.1.4 Minimum depth. Exterior footings shall be placed not less than 12 inches (305 mm) below the undisturbed ground surface. Where applicable, the depth of footings shall also conform to Sections R403.1.4.1 through R403.1.4.2. Deck footings shall be in accordance with Section R507.3.

R403.1.4.1 Frost protection. Except where otherwise protected from frost, foundation walls, piers and other permanent supports of buildings and structures shall be protected from frost by one or more of the following methods:

1. Extended below the frost line specified in Table R301.2.(1).
2. Constructed in accordance with Section R403.3.
3. Constructed in accordance with ASCE 32.
4. Erected on solid rock.

Footings shall not bear on frozen soil unless the frozen condition is permanent.

Exceptions:

1. Protection of free-standing accessory structures with an area of 600 square feet (56 m²) or less, of light-frame construction, with an eave height of 10 feet (3048 mm) or less shall not be required.
2. Protection of free-standing accessory structures with an area of 400 square feet (37 m²) or less, of other than light-frame construction, with an eave height of 10 feet (3048 mm) or less shall not be required.
3. Decks not supported by a dwelling need not be provided with footings that extend below the frost line.

Reason: The Deck Code Coalition (DCC) is intending to clean up Chapter 4 by pointing out that deck footing details are in Section R507. Section R507 is further cleaned up by relocating exceptions of R507.3.2 into R507.3 because the exceptions are not related to footing depth but rather about when footings not required.

The DCC added a new section dealing with footings in frost prone areas by borrowing from R403.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The Deck Code Coalition does not anticipate any cost impact.

The text exceptions were not modified, only relocated to a more appropriate section.

The new section on frost protection was moved from Chapter 4 to Chapter 5.

Proposal # 4303
**2018 International Residential Code**

Revise as follows:

**R507.5 Deck Beams.** Maximum allowable spans for wood deck beams, as shown in Figure R507.5, shall be in accordance with Table R507.5. Beam plies shall be fastened together with two rows of 10d (3-inch × 0.128-inch) nails minimum at 16 inches (406 mm) on center along each edge. Beams shall be permitted to cantilever at each end up to one-fourth of the allowable beam span. Deck beams of other materials shall be permitted where designed in accordance with accepted engineering practices.

**Reason:** As the original authors of Section R507 in the 2015 IRC, the DCC wanted to clarify that Section R507.5 intended to mean that multi-ply beams are required to be fastened together in order to perform as intended. When multi-ply beams are connected together with 10d nails at 16° o.c., their depth to width ratio resists top chord bending.

It appears that some folks are still building deck beams and separating plies.

Figures R507.5.1(1) and (2) tried to cover this, but it appears that some folks do not understand the intent. Hopefully the new word will strengthen the understanding and eliminate the poor construction practice.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. There should be no increased cost related to this proposal. There is no change in the intent of the code from the 2018 version.
RB189-19

IRC®: R507.5

Proponent: Deck Code Coalition, Charles Bajnai (chair), North American Deck and Railing Assoc (NADRA), retired, representing Deck Code Coalition (csbajnai@gmail.com)

2018 International Residential Code

Revise as follows:

R507.5 Deck Beams. Maximum allowable spans for wood deck beams, as shown in Figure R507.5, shall be in accordance with Table R507.5. Beam plies shall be fastened with two rows of 10d (3-inch × 0.128-inch) nails minimum at 16 inches (406 mm) on center along each edge. Beams shall be permitted to cantilever at each end up to one-fourth of the actual beam span. Deck beams of other materials shall be permitted where designed in accordance with accepted engineering practices.

Reason: The Deck Code Coalition (DCC) submits this code change because the cantilever length should be governed by the actual beam span, not the allowable beam span.

Example:

- A 2x12 beam may be allowed to span 16 feet based on the imposed load, but may be actually only spanning 4 feet.
- The maximum cantilever should be 1 foot, not 4 feet.
- In this example, the old text would have allowed a 4 foot cantilever with a 4’ back span.
- Back span must be at least 4x the cantilever length.

Cost Impact: The code change proposal will increase the cost of construction

This proposal might increase the cost of construction because the contractor would not be able to extend cantilevers out as far without increasing beam size.

</tr>
</tbody>
</table>

J = actual joist span length (feet)

C = actual joist cantilever length (feet)

Reason: The current beam span table incorporates a conservative assumption that all deck joists cantilever the
allowable ¼ of the main span past the beam. This assumption is included in the calculated tributary area of the beam design within the headings of deck joist span. The proposed footnote adds a factor that allows this assumption to be counteracted so that designers that do not use a full cantilever do not have to overdesign the beam.

Example:

A deck is designed using Southern Pine, (2) 2x10

Joist span is 12’ and no cantilever.

</tr>
</tbody>
</table>

- C = 0 feet
- J = 12 feet
- The existing table would say the maximum beam span length would be 7’-4”

Applying the adjustment factor

- C / J = 0 and the joist span factor calculates out to .66
- The effective joist span can be adjusted as .66 x 12 = 8 feet
- The maximum beam span length is 9’-0” since there is no cantilever.

Note: The beam length is not reduced by .66, but rather the effective joist span length is reduced by .66.

Also there were a few minor adjustments to the titles in the table. They were done to help add clarity to the table.

Cost Impact: The code change proposal will decrease the cost of construction.
If the deck is constructed with a cantilevered beam, the beam may be able to be downsized if it is constructed.
with a cantilever that is not at its maximum length. For some decks this could save a few dollars with smaller beam material.
2018 International Residential Code

Revise as follows:

R507.7 Decking. Maximum allowable spacing for joists supporting wood decking, excluding stairways, shall be in accordance with Table R507.7. Wood decking shall be attached to each supporting member with not less than two 8d threaded nails or two No. 8 wood screws. Maximum allowable spacing for joists supporting plastic composite decking shall be in accordance with Section R507.2. Other approved decking or fastener systems shall be installed in accordance with the manufacturer’s installation requirements.

**TABLE R507.7**  
MAXIMUM JOIST SPACING FOR WOOD DECKING

<table>
<thead>
<tr>
<th>DECKING MATERIAL TYPE AND NOMINAL SIZE</th>

<td>In accordance with Section R507.2</td>
<td></td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 degree = 0.01745 rad.

a. Maximum angle of 45 degrees from perpendicular for wood deck boards.

b. Or other maximum span provided by an accredited lumber grading or inspection agency.

c. Individual wood deck boards supported by two joists shall be considered *single span* and three or more joists shall be considered *multi-span*.

**Reason:** The Deck Code Coalition proposes to replace the existing decking span table to correct:
1. the allowable span for 2x wood,
2. allow lumber grading or inspection agencies to rate 5/4” decking for longer spans, and
3. provide values for single span conditions.

Currently, the table is overly conservative for 2x material. When evaluated per the American Lumber Standards Committee’s (ALSC) decking policy, 2x nominal material can span 24 inches instead of the 16 inches currently allowed.

Similarly, 5/4 inch decking is rated per ALSC's decking policy. While the minimum rated span is 16 inches, for stronger species or grades, the allowable rated span can be larger. The proposed table keeps the conservative baseline while increasing flexibility to manufacturers and designers.
Lastly, the ALSC policy is for evaluation of decking with two-span conditions, which is an unstated assumption in the current table. The proposed table not only exposes that assumption but also gives values for single-span conditions that may be impossible to avoid for some decking layouts.

For information for the ALSC decking policy refer to

http://www.alsc.org/greenbook%20collection/UntreatedProgram_EvaluationofRecommendedSpans.PDF

**Cost Impact:** The code change proposal will decrease the cost of construction
The code change proposal will decrease the cost of construction. There might be a reduced cost if a builder is laying decking on the diagonal. The other items in the table remain the same.
2018 International Residential Code

Revise as follows:

R507.9.1.2 Band joist details. Band joists supporting a ledger shall be a minimum 2-inch-nominal (51 mm), solid-sawn, spruce-pine-fir or better lumber or a minimum 1-inch by 9-1/2-inch (25 mm × 241 mm) dimensional, Douglas fir or better, laminated veneer lumber) nominal engineered wood rim boards in accordance with Section R502.1.7. Band joists shall bear fully on the primary structure capable of supporting all required loads.

Reason: This proposal requires the band joists used to attach the deck ledger to be in compliance with sawn lumber or the engineered wood rim board, which is recognized in R502.1.7. The current language restricts the band joists to be a minimum of 1-inch by 9-1/2-inch dimensional, Douglas fir or better, laminated veneer lumber. This proposal retains the minimum rim joist thickness of 1 inch but removes the minimum depth of 9-1/2-inch because the framing members might be less than 9-1/2 inches, such as 10x dimension lumber with a net depth of 9-1/4 inches or 8x with a net depth of 7-1/4 inches. In addition, based on Section R502.1.7, band joists qualified under ANSI/APA PRP 410 or ASTM D7672 include engineered wood products beyond "Douglas-fir laminated veneer lumber" (LVL). It should be noted that the ledger connection for the qualified band joists is required by ANSI/APA PRP 410 or ASTM D7672 to be tested at 5 times or more of the design capacity used to develop the current IRC Table R507.9.1.3(1).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is intended to clarify the reference of the band joists based on the code.

Proposal # 4663

</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s; 1 ksi = 6.895 MPa.

<sup>a</sup> Nails are smooth-common, box or deformed shanks except where otherwise stated. Nails used for framing and sheathing connections shall have minimum average bending yield strengths as shown: 80 ksi for shank diameter of 0.192 inch (20d common nail), 90 ksi for shank diameters larger than 0.142 inch but not larger than 0.177 inch, and 100 ksi for shank diameters of 0.142 inch or less.

<sup>b</sup> Staples are 16 gage wire and have a minimum 1/16-inch on diameter crown width.

<sup>c</sup> Nails shall be spaced at not more than 6 inches on center at all supports where spans are 48 inches or greater.

<sup>d</sup> Four-foot by 8-foot or 4-foot by 9-foot panels shall be applied vertically.

<sup>e</sup> Spacing of fasteners not included in this table shall be based on Table R602.3(2).
f. For wood structural panel roof sheathing attached to gable end roof framing and to intermediate supports within 48 inches of roof edges and ridges, nails shall be spaced at 6 inches on center where the ultimate design wind speed is less than 130 mph and shall be spaced 4 inches on center where the ultimate design wind speed is 130 mph or greater but less than 140 mph.

g. Gypsum sheathing shall conform to ASTM C1396 and shall be installed in accordance with GA 253. Fiberboard sheathing shall conform to ASTM C208.

h. Spacing of fasteners on floor sheathing panel edges applies to panel edges supported by framing members and required blocking and at floor perimeters only. Spacing of fasteners on roof sheathing panel edges applies to panel edges supported by framing members and required blocking. Blocking of roof or floor sheathing panel edges perpendicular to the framing members need not be provided except as required by other provisions of this code. Floor perimeter shall be supported by framing members or solid blocking.

i. Where a rafter is fastened to an adjacent parallel ceiling joist in accordance with this schedule, provide two toe nails on one side of the rafter and toe nails from the ceiling joist to top plate in accordance with this schedule. The toe nail on the opposite side of the rafter shall not be required.

j. RSRS-01 is a Roof Sheathing Ring Shank nail meeting the specifications in ASTM F1667.

**Reason:** IRC Table R602.3(1) and IBC Table 2304.10.1 are essentially the same table in terms or structural connections. Although the connections are closely aligned, there are variations in the prescribed fastener in the
two tables. Some fasteners are prescribed in the IRC table and not in the IBC table and others are prescribed in the IBC table and not the IRC table. This proposal is written to harmonize the fasteners between the two tables. In addition, where additional information exists in one table and not the other, this too is being harmonized.

For connection # 2,6,18,19, 20 & 23 there was a code change proposal RB272-13 entered in by the American Wood Council for the 2015 IRC. The reference nail values for the nailing schedule were based on Reference Lateral Values and Reference Withdrawal values. All other connections in the table were based on Reference Lateral Design Values. In the 2018 NDS, the reference withdrawal values for stainless steel nails were tabulated in a new NDS table (12.2D). The withdrawal values for stainless steel are lower than the values for carbon steel (bright or galvanized) nails of equivalent diameters.

As such, the lower stainless steel withdrawal values combined with the publication date of the 2018 NDS and the 2015 code proposal date would indicate that the basis of the original code proposal is relevant to only carbon steel nails and not to stainless steel nails. The added note to these connections is to exclude stainless steel from these connections based on the lower withdrawal values.

Connection 1:

Added 14 gage staple from IBC 2304.10.1

Added Blocking Between Rafters or Truss not at the wall top plate to rafter or truss from IBC 2304.10.1

Added flat blocking to truss and web filler from IBC 2304.10.1

Connection 2:

Added note regarding stainless steel fasteners

Added 14 gage staples from IBC 2304.10.1

Connection 3, 5

Added 14 gage staples from IBC 2304.10.1

Connection 6

Added note regarding stainless steel fasteners

Added 14 gage staples from IBC 2304.10.1

Connections 7, 8, 9, 12, 13, 14, 15, 16, 17

Added 14 gage staples from IBC 2304.10.1

Connection 15

Changed fastener spacing and location description to match IBC 2304.10.1

Connection 18
Added note regarding stainless steel fasteners

Added 3" x 0.131" nails from IBC 2304.10.1

Added 14 gage staples from IBC 2304.10.1 and eliminated the 16 gage staple reference

Connections 19 & 20

Added note regarding stainless steel fasteners

Connection 21 & 22

Added 14 gage staples from IBC 2304.10.1

Connection 23

Added note regarding stainless steel fasteners

Connections 27, 28 & 29

Added 14 gage staples from IBC 2304.10.1

Connection 30:

The roof fasteners have been separated from the subfloor and wall fasteners for better clarification when reading

Connection 31:

Panel thickness range is changed to match the thickness range in the IBC.

Connection 32:

Panel thickness range is changed to match the thickness range in the IBC. Additionally, the description 8d deformed (2½" x 0.131") in an incorrect description. ASTM F1667 does not have a classification for 8d deformed. The correct description is a deformed 2½" x 0.131" nail.

Connections 33-34

The current nail descriptions are incomplete and missing a shank diameter. These changes match SDPWS

Connection 35-36

The current nail descriptions are incomplete and missing a shank diameter.

Connection 37:

Adding the deformed 2" x 0.113" nail will harmonize with the IBC table. A 6d deformed 2" x 0.120" nail is not addressed in ASTM F1667. The correct description is a deformed 2" x 0.120" nail and should be used to avoid
Connection 38 & 39:

An 8d deformed 2½" x 0.120 nail is not addressed in ASTM F1667. The correct description is a deformed 2½" x 0.120 nail and should be used to avoid confusion.

Footnote b. deleted because of the addition of the 14 gage staples to the table

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed changes should not change cost of construction as it harmonizes the fasteners between the IBC and IRC.

Proposal # 3958

RB193-19
RB194-19
IRC®: TABLE R602.3(1), R602.7.5

Proponent: Paul Coats, representing American Wood Council (pcoats@awc.org)

2018 International Residential Code
Revise as follows:

TABLE R602.3(1)
FASTENING SCHEDULE

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>ITEM</th>
<th>DESCRIPTION OF BUILDING ELEMENTS</th>
<th>NUMBER AND TYPE OF FASTENER&lt;sup&gt;a, b, c&lt;/sup&gt;</th>
<th>SPACING AND LOCATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>Adjacent full-height stud to end of header</td>
<td>4-16d box (3 1/2&quot; x 0.135&quot;; or 3-16d common (3 1/2&quot; x 0.162&quot;); or 4-10d box (3&quot; x 0.128&quot;;); or 4 - 3&quot; x 0.131&quot;</td>
<td>End nail</td>
</tr>
</tbody>
</table>

R602.7.5 Supports for headers. Headers shall be supported on each end with one or more jack studs or with approved framing anchors in accordance with Table R602.7(1) or R602.7(2). The full-height stud adjacent to each end of the header shall be end nailed to each end of the header in accordance with four 16d nails (3.5 inches x 0.135 inches Table R602.3(1)). The minimum number of full-height studs at each end of a header shall be in accordance with Table R602.7.5-R602.7.5.

Reason: This proposal makes no technical changes, but simply places the required nailing of the first full-height stud adjacent to the header into the fastening schedule table with the other structural connections, so it can be found more easily and to avoid correlation problems in the future. Additional full-height studs would be fastened to each other in accordance with row 8 of Table R602.3(1), “Stud to stud (not at braced wall panels)” or row 9, “Stud to stud and abutting studs at intersection wall corners (at braced wall panels).” The only change to Table R602.3(1) is the addition of a new row 12 and the renumbering of subsequent rows.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposal does not change requirements but changes location of a requirement and adds options for nailing.

Proposal # 4274
Proponent: Tim Earl, representing The Gypsum Association (tearl@gbhinternational.com)

2018 International Residential Code
Revise as follows:

**TABLE R602.3(1)**
FASTENING SCHEDULE

Portions of table not shown remain unchanged.

</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s; 1 ksi = 6.895 MPa.

Gypsum sheathing shall conform to ASTM C1396 and shall be installed in accordance with GA 253 or ASTM C1280. Fiberboard sheathing shall conform to ASTM C208.

Add new standard(s) as follows:

**ASTM**

ASTM International
100 Barr Harbor Drive, P.O. Box C700
West Conshohocken PA 19428

**C1280-18: Standard Specification for Application of Exterior Gypsum Panel Products for Use as Sheathing**

Reason: This adds the ASTM standard as an alternative to the GA (industry) standard for those who may wish to refer preferentially to the ASTM document. In practice there is no difference between the two documents.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. This simply adds another referenced standard as an option, with no impact on cost.

Staff Analysis: The referenced standard, ASTM C1280-18, is currently referenced in other 2018 I-codes.
**2018 International Residential Code**

Revise as follows:

**TABLE R602.3(1)**

<table>
<thead>

</tbody>
</table>
|      |                                 |                            | 6d common (2” × 0.113”) nail (subfloor, wall); or RSRS-01 (2¹/₂” × 0.131”) nail (roof) | 6
| 30   | 3/8” − 1½”                      | 6d common (2” × 0.113”) nail (subfloor, wall); or RSRS-01 (2¹/₂” × 0.131”) nail (roof) | 6
| 31   | 19/32” − 1”                     | 8d common nail (2¹/₂” × 0.131”); or RSRS-01 (2³/₈” × 0.113”) nail (roof) | 6
| 32   | 1¹/₆” − 1¹/₄”                   | 10d common (3” × 0.148”) nail; or 8d (2¹/₂” × 0.131”) deformed nail | 6

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s; 1 ksi = 6.895 MPa.

f. For wood structural panel roof sheathing attached to gable end roof framing and to intermediate supports within 48 inches of roof edges and ridges, nails shall be spaced at 6 4 inches on center where the ultimate design wind speed is less than 130 mph and shall be spaced 4 inches on center where the ultimate design wind speed is greater but less than 140 mph, greater than 130 mph in Exposure B or greater than 110 mph in Exposure C.

Reason: AWC submitted two proposals on roof sheathing nailing last cycle, RB222-16 that included modifications for ASCE 7-16 wind loads and RB221-16 that included modifications for ASCE 7-10 wind loads. AWC requested disapproval of the ASCE 7-16 wind load version based on the approval of RB221-16 which updated roof sheathing nailing in Table R602.3(1) to ASCE 7-10 wind loads. AWC is now resubmitting a proposal to update roof sheathing nailing in Table R602.3(1) to be based on ASCE7-16 wind loads and to agree with roof sheathing nailing in the 2018 Wood Frame Construction Manual. Wind uplift nailing requirements for common species of roof framing with specific gravities of 0.42 or greater (e.g. SPF, Hem-Fir) are the basis of the proposed nail spacing requirements in Table R602.3(1) to meet the wind uplift loading requirements per ASCE 7-16 without being overly complex in specification of roof sheathing nailing. The basic nailing proposed is 6” o.c. at panel edges and 6” o.c. at intermediate supports in the field of the panel. As shown in the boxed cells.
of 2018 WFCM, Table 3.10A for the common case of roof framing spaced at 24 inches on center, nailing at intermediate supports in the interior portions of the roof is 6" o.c. for wind speeds within the scope of IRC. The 6" o.c. spacing is also appropriate for edge zones except where ultimate wind speeds equal or exceed 130 mph in Exposure B and 110 mph in Exposure C where 4" o.c. nailing is needed. These special cases are addressed by the proposed modification to footnote f.

<td>2</td>
</tr>
<tr>
<td>1x10 or Larger Sheathing</td>
<td>12-19.2</td>
<td>3</td>
</tr>
</tbody>
</table>

---

E - Nail spacing at panel edges (in.)
F - Nail spacing at intermediate supports in the panel field (in.)

1. For roof sheathing within 4 feet of the perimeter edge of the roof, including 4 feet on each side of the roof peak, the 4 foot perimeter edge shall be used.
2. For wind speeds greater than 130 mph, blocking is required which transfers lateral load to two additional joints (3 joints total).
3. See Table 3.10 for other fastener and sheathing combinations.
4. Tabulated values for 8d common and 10d box nails are applicable to carbon steel nails (bright or galvanized).
Cost Impact: The code change proposal will increase the cost of construction. The change in the spacing of the nails for the small portions of roofs will result in an increase in the cost due to the increased number of nails and the time to install them, but that cost should be negligible when considering the overall cost for the construction of a dwelling.
Proponent: Rick Allen, International Staple, Nail and Tool Association, representing International Staple, Nail and Tool Association (rallen@isanta.org)

2018 International Residential Code

</tbody>
</table>
For SI: 1 inch = 25.4 mm.

a. Nail is a general description and shall be permitted to be T-head, modified round head or round head.
b. Staples shall have a minimum crown width of \( \frac{7}{16} \) inch on diameter except as noted.
c. Nails or staples shall be spaced at not more than 6 inches on center at all supports where spans are 48 inches or greater. Nails or staples shall be spaced at not more than 12 inches on center at intermediate supports for floors.
d. Fasteners shall be placed in a grid pattern throughout the body of the panel.
e. For 5-ply panels, intermediate nails shall be spaced not more than 12 inches on center each way.
f. Hardboard underlayment shall conform to CPA/ANSI A135.4

g. Specified alternate attachments for roof sheathing shall be permitted where the ultimate design wind speed is less than 130 mph. Fasteners attaching wood structural panel roof sheathing to gable end wall framing shall be installed using the spacing listed for panel edges.
h. Fiber-cement underlayment shall conform to ASTM C1288 or ISO 8336, Category C.

Reason: Under Floor Underlayment - Fiber Cement - 1/4 thick
The description "3d" does not describe an actual length and shank diameter of the nail. These dimensions have been added to provide the requirements of the nails.

Under Floor Underlayment - Hardboard - .200 thick

a 1½ long ring grooved underlayment nail is an incomplete and incorrect description. A shank diameter needs to be provided and per ASTM F1667 a diameter of 0.080 is provided, which matches the diameter of the sinker nail on the second line of the table. The term "ring-grooved" should read "ring shank" to be consistent with other descriptions in the code.

a 4d sinker nail is 1 3/8" long x 0.080" shank diameter. Providing dimensions of 1 3/8 x 0.080" will be consistent with other descriptions in the code. The term "cement" coated has been removed from ASTM F1667 and replaced with "polymer" coated

Under Floor Underlayment - Particle board - all three material thickness, the terms 4d and 6d underlayment nail are not referenced in ASTM F1667 and the descriptions do not provide dimensional requirements for the nails. The correct designation is 1 1/2 " x 0.099" and 2" x 0.120" respectively. The term ring-grooved should read ring shank to be consistent with other descriptions in the code.

Footnote b., staple crowns are not "on diameter". Simply stating the crown width is corrects.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
These changes just provide clarity to incorrect or incomplete descriptions and do not affect the cost of construction.

</tbody>
</table>

For SI: 1 inch = 25.4 mm.

- a. Nail is a general description and shall be permitted to be T-head, modified round head or round head.
- b. Staples shall have a minimum crown width of \(\frac{7}{16}\)-inch on diameter except as noted.
- c. Nails or staples shall be spaced at not more than 6 inches on center at all supports where spans are 48 inches or greater. Nails or staples shall be spaced at not more than 12 inches on center at intermediate supports for floors.
- d. Fasteners shall be placed in a grid pattern throughout the body of the panel.
- e. For 5-ply panels, intermediate nails shall be spaced not more than 12 inches on center each way.
- f. Hardboard underlayment shall conform to CPA/ANSI A135.4
- g. Specified alternate attachments for roof sheathing shall be permitted where the ultimate design wind speed is less than 130 mph. Fasteners attaching wood structural panel roof
sheathing to gable end wall framing shall be installed using the spacing listed for panel edges.
or equal to 110 mph, roof sheathing attachment using the specified alternate fasteners shall be
permitted where fasteners are installed 3 inches on center at all supports.

h. Fiber-cement underlayment shall conform to ASTM C1288 or ISO 8336, Category C.

Reason: The proposed revision to footnote g is intended to update the alternative fastening to uplift loading
requirements per ASCE 7-16 without being overly complex in specification of roof sheathing attachment
schedules. The reference calculation leading to use of 3” o.c. spacing at all locations is based on the 0.099”
diameter and 0.113” diameter nail shank withdrawal from wood framing with specific gravity equal to 0.42 and
pre-calculated wind uplift loads in WFCM Table 3.10. The use of a single 3” spacing at all supports was
extended to staples based on the assumption that the ASCE 7-16 load increase would similarly require reduced
spacing. This assumption was applied to staples because a withdrawal value is not available for staples in the
NDS.

Cost Impact: The code change proposal will increase the cost of construction
The reduced spacing of fasteners to meet wind uplift loading will increase cost of construction, but given the
increase only applies to the roof, that cost increase should be negligible when considering the overall cost for
the construction of a dwelling.

Proposal # 5529

RB198-19
2018 International Residential Code

Revise as follows:

R602.10.1.2 Offsets along a Location of braced wall line: lines and permitted offsets. Where braced wall panels along a braced wall line fall in a single line, the braced wall line shall be located at those braced wall panels. Where braced wall panels are offset out of plane, the braced wall line shall be located at or between the braced wall panels, and the braced wall line shall not be located outboard or inboard of all the braced wall panels in that braced wall line. Where 2/3 or more of the length of braced wall panels in a braced wall line fall in a single line, the braced wall line shall be located at those braced wall panels; or the braced wall line shall be located at the centroid of the braced wall panels, as seen in Figure R602.10.1.1.

Exterior braced wall panels parallel to a braced wall line shall be offset not more than 4 feet (1219 mm) from the designated braced wall line location as shown in Figure R602.10.1.1.

Exterior walls parallel to a braced wall line shall be offset not more than 4 feet (1219 mm) from the designated braced wall line location as shown in Figure R602.10.1.1.

Interior walls used as bracing shall be offset not more than 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1.
FIGURE R602.10.1.1
BRACED WALL LINES

Reason: Over a series of cycles, changes to the IRC Section R602.10 wall bracing provisions have caused some of the important concepts fundamental to the development of the bracing provisions to be lost. This was highlighted in a recent request for interpretation of the location of braced wall lines relative to exterior walls. Going back to the 2006 IRC, and previous IRC and legacy codes, braced wall panels were required at the exterior walls, and additional interior braced wall panels and lines were required when needed to meet braced wall line spacing requirements. The concept that exterior walls are to be braced appears to not be specifically stated in the IRC from the 2009 edition forward. With this concept not included, these provisions are lacking specific requirements as to where the braced wall lines are to be located.

This proposal fills this gap by adding discussion of the location of braced wall lines relative to the braced wall panels. The current provisions discussing the location of braced wall lines relative to exterior walls are retained as these will control permitted locations of exterior walls if other than at the braced wall panels.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

This proposal is editorial to clarify the intent of the current provisions.

Proposal # 5272

RB199-19
Revise as follows:

R602.10.2.2 Locations of braced wall panels. A braced wall panel shall begin within 10 feet (3810 mm) from each end of a braced wall line as determined in Section R602.10.1.1. The distance between adjacent edges of braced wall panels along a braced wall line shall be not greater than 20 feet (6096 mm) as shown in Figure R602.10.2.2.

Exceptions:

1. Braced wall panels in Seismic Design Categories D0, D1, and D2 shall comply with Section R602.10.2.2.1.
2. Braced wall panels with continuous sheathing in Seismic Design Categories A, B, or C shall comply with Section R602.10.7.

R602.10.2.2.1 Location of braced wall panels in Seismic Design Categories D D0, D1 and D2. Braced wall panels shall be located at each end of a braced wall line.

Exception Exceptions:

1. Braced wall panels constructed of Method WSP or BV-WSP and continuous sheathing methods as specified in Section R602.10.4 shall be permitted to begin not more than 10 feet (3048 mm) from each end of a braced wall line provided that each end complies with one of the following:

   1.1. A minimum 24-inch-wide (610 mm) panel for Methods WSP, CS-WSP, CS-G and CS-PF is applied to each side of the building corner as shown in End Condition 4 of Figure R602.10.7.

   1.2. The end of each braced wall panel closest to the end of the braced wall line shall have an 1,800 lb (8 kN) hold-down device fastened to the stud at the edge of the braced wall panel closest to the corner and to the foundation or framing below as shown in End Condition 5 of Figure R602.10.7.

2. Braced wall panels constructed of Method PFH or ABW, or of Method BV-WSP where a hold-down is provided in accordance with Table R602.10.6.5, shall be permitted to begin not more than 10 feet from each end of a braced wall line.

Reason: The goal of this code change is to resolve conflicts in the code and prevent confusion on how to interpret this section.

This section deals with placement of braced wall panels on a wall. The main requirement is that the panel can be placed up to 10 feet from the wall. But there are two exceptions. One is the SDC D0, D1, and D2 requirements of the next section, and the other are the continuous sheathing requirements that are located pages and pages away in the code. Since they conflict, it make sense to combine them into one section so that they work together. By adding the exceptions, it clarifies in which case each of the rules on corner panels is to be applied.
The second part of this change is to clarify the exception in R602.10.2.2.1 for bracing in Seismic Design Categories D0, D1, and D2. Braced wall panels are allowed to be located up to 10 feet from the corner when the braced wall panel has an 1800 pound hold-down. There are certain kinds of braced wall panels that already have a holdown of this capacity or higher. ABW has a minimum of an 1800 pound hold-down required, and PFH has a 3500 pound hold-down required. Also, most cases of BW-WSP require a hold-down with a capacity in excess of 1800 pounds. However, there is one case where BV-WSP does not require a holdown, to that is taken into account here by adding the wording "where a hold-down is provided in accordance with Table R602.10.6.5."

The purpose of the corner panels or hold-downs in this section is to restrain the first braced wall panel from overturning, either by having it located at a corner, or by providing a hold-down. These braced wall panel methods that already have the hold-down are restrained from overturning so they can be located away from the corner.

This change also attempts to answer the question that arises sometimes of whether the capacity of the holdown of an ABW, PFH, or BV-WSP needs to be increased by 1800 pounds when it is located up to 10 feet from a corner. The intent is for the ABW, PFH, or BV-WSP to be adequate as specified. That is why they are broken out into a second exception.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The goal of this change is just to clarify the code. No additional requirements are added.

Proposal # 5168

RB200-19
2018 International Residential Code

Revise as follows:

### TABLE R602.10.3(2)

**WIND ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING**

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>ITEM NUMBER</th>
<th>ADJUSTMENT BASED ON</th>
<th>STORY/SUPPORTING CONDITION</th>
<th>ADJUSTMENTFACTOR&lt;sup&gt;a&lt;/sup&gt;,&lt;sup&gt;b&lt;/sup&gt;[multiply length fromTable R602.10.3(1) bythis factor]</th>
<th>APPLICABLE METHODS</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Horizontal blocking</td>
<td>Any story</td>
<td>2.0</td>
<td>WSP, SFB, PBS, HPS, CS-WSP</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 4.48 N.

a. Linear interpolation shall be permitted.
b. The total adjustment factor is the product of all applicable adjustment factors.
c. The adjustment factor is permitted to be 1.0 when determining bracing amounts for intermediate braced wall lines provided the bracing amounts on adjacent braced wall lines are based on a spacing and number that neglects the intermediate braced wall line.
d. The same adjustment factor shall be applied to all braced wall lines on all floors of the structure, based on the worst-case exposure category.

### TABLE R602.10.3(4)

**SEISMIC ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING**

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>ITEM NUMBER</th>
<th>ADJUSTMENT BASED ON</th>
<th>STORY</th>
<th>CONDITION</th>
<th>ADJUSTMENTFACTOR&lt;sup&gt;a&lt;/sup&gt;,&lt;sup&gt;b&lt;/sup&gt;[Multiply length fromTable R602.10.3(3) by thisfactor]</th>
<th>APPLICABLE METHODS</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Horizontal blocking</td>
<td>Any story</td>
<td>Horizontal blocking omitted</td>
<td>2.0</td>
<td>WSP, SFB, PBS, HPS, CS-WSP</td>
</tr>
</tbody>
</table>

For SI: 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Linear interpolation shall be permitted.
b. The total length of bracing required for a given wall line is the product of all applicable adjustment factors.
c. The length-to-width ratio for the floor/roof diaphragm shall not exceed 3:1.
d. Applies to stone or masonry veneer exceeding the first story height.
e. The adjustment factor for stone or masonry veneer shall be applied to all exterior braced wall lines and all braced wall lines on the interior of the building, backing or perpendicular to and laterally supporting veneered walls.
f. See Section R602.10.6.5 for requirements where stone or masonry veneer does not exceed the first-story height.

**Reason:** While the current adjustment factor is based on blocked and unblocked full-scale wood structural panel testing, it is only logical that other panel products, including SFB, PBS, and HPS, would respond to the same nailing omissions. It is also reasonable to conclude that these other panel products would be equally affected by omitting panel blocking at horizontal joints. As it stands, the SFB, PBS, and HPS can be used without horizontal blocking and do not need to take the same reduction as wood structural panels. This is not supported by testing or common sense, is not conservative, and needs to be updated. This code change adds SFB, PBS, and HPS to both wind and seismic adjustment tables.

**Cost Impact:** The code change proposal will increase the cost of construction. This code change could increase the cost of construction when using the SFB, HPS, and PBS products as it requires additional nailing and blocking at horizontal panel joints. It does however clarify the intent of the code over a wider range of panel products, common or otherwise.
2018 International Residential Code
Revise as follows:

TABLE R602.10.3(3)
BRACING REQUIREMENTS BASED ON SEISMIC DESIGN CATEGORY

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>Seismic Design Category</th>
<th>Story Location</th>
<th>Braced Wall Line Length (feet)</th>
<th>Method LIB</th>
<th>Method GB</th>
<th>Method DWB, SFB, PBS, PCP, HPS, CS-SFB</th>
<th>Method WSP</th>
<th>Method CS-WSP, CS-G, CS-PF</th>
</tr>
</thead>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

NP = Not permitted.

a. Linear interpolation shall be permitted.
b. Wall bracing lengths are based on a soil site class “D.” Interpolation of bracing lengths associated with the seismic design categories shall be permitted when a site-specific S\text{ds} value is determined in accordance with Section 1613.2 of the International Building Code.
c. Where the braced wall line length is greater than 50 feet, braced wall lines shall be permitted to be divided into shorter segments having lengths of 50 feet or less, and the amount of bracing within each segment shall be in accordance with this table.
d. Method LIB shall have gypsum board fastened to not less than one side with nails or screws in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches.
e. Methods PFG and CS-SFB do not apply in Seismic Design Categories D₀, D₁ and D₂.
f. Where more than one bracing method is used, mixing methods shall be in accordance with Section R602.10.4.1.

Reason: As of the last code update cycle, the Seismic Design Categories were no longer based exclusively on
site class D, so this statement is in error. Because it is not needed for application of the provisions, this statement can be deleted. It is still permitted to determine Seismic Design Category per the provisions of the IBC, so footnote b is retained and is now referenced from the top of the Seismic Design Category column.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is an editorial clarification of existing provisions and has no cost impact.
RB203-19
IRC®: TABLE R602.10.3(3)

Proponent: Randy Shackelford, representing Simpson Strong-Tie Co. (rshackelford@strongtie.com)

2018 International Residential Code

Revise as follows:

**TABLE R602.10.3(3)**
BRACING REQUIREMENTS BASED ON SEISMIC DESIGN CATEGORY

<table>
<thead>
<tr>
<th>Seismic Design Category</th>
<th>Story Location</th>
<th>Braced Wall Line Length (feet)</th>
<th>Method LIB&lt;sup&gt;d&lt;/sup&gt;</th>
<th>Method GB</th>
<th>Methods DWB, SFB, PBS, PCP, HPS, CS-SFB&lt;sup&gt;e&lt;/sup&gt;</th>
<th>Methods WSP&lt;sup&gt;†&lt;/sup&gt;, PFH, PFG&lt;sup&gt;†&lt;/sup&gt; and ABW</th>
<th>Methods CS-WSP, CS-G, CS-PF</th>
</tr>
</thead>
</table>

Portions of table not shown remain unchanged.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

NP = Not Permitted.

a. Linear interpolation shall be permitted.
b. Wall bracing lengths are based on a soil site class “D.” Interpolation of bracing length between the $S_{ds}$ values associated with the seismic design categories shall be permitted when a site-specific $S_{ds}$ value is determined in accordance with Section 1613.2 of the International Building Code.
c. Where the braced wall line length is greater than 50 feet, braced wall lines shall be permitted to be divided into shorter segments having lengths of 50 feet or less, and the amount of bracing within each segment shall be in accordance with this table.
d. Method LIB shall have gypsum board fastened to not less than one side with nails or screws in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches.
e. Methods PFG and CS-SFB do not apply in Seismic Design Categories D0, D1 and D2.
f. Where more than one bracing method is used, mixing methods shall be in accordance with Section R602.10.4.1.

Reason:
Last cycle, the tables for Bracing Requirements Based on Wind Speed and Bracing Requirements Based on Seismic Design Category were revised so that they included all the permissible bracing methods. For some reason, three permissible bracing methods were left off of Table R602.10.3(3). So we are proposing to add methods ABW, PFH, and PFG in to the table in the WSP column heading. ABW, PFH, and PFG are intermittent bracing methods that have amounts of bracing based on their equivalency to a WSP braced wall panel.
Note that Method PFG is only permitted in Seismic Design Categories A, B, and C per Section R602.10.6, but footnote e already reflects that. So the only action needed is to add the reference to footnote e. This method has to be listed because there are also requirements for Townhouses in SDC C in this table.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is meant to only clarify that Braced Wall Panel methods ABW, PFH, and PFG are permitted to be used in SDC C townhomes and that ABW and PFH are permitted to be used in Seismic Design Categories D0, D1, and D2. If anything, there could be a decrease in cost if builders were able to use a more economical method because of this clarification.

For SI: 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Linear interpolation shall be permitted.
b. The total length of bracing required for a given wall line is the product of all applicable adjustment factors.
c. The length-to-width ratio for the floor/roof diaphragm shall not exceed 3:1.
d. Applies to stone or masonry veneer exceeding the first story height.
e. The adjustment factor for stone or masonry veneer shall be applied to all exterior braced wall lines and all braced wall lines on the interior of the building, backing or perpendicular to and laterally supporting veneered walls.
f. See Section R602.10.6.5 for requirements where stone or masonry veneer does not exceed the first-story height.
g. One- and two-family dwellings in Seismic Design Category D<sub>2</sub> exceeding two stories shall be designed in accordance with accepted engineering practice.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N. NP = Not Permitted. NA = Not Applicable.

**a.** One- and two-family dwellings in Seismic Design Category **D₂** exceeding two stories shall be designed in accordance with accepted engineering practice.

**a- b.** Hold-down force is minimum allowable stress design load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single-story hold-down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained.

**b- c.** Where hold-down connectors from stories above align with stories below, use cumulative hold-down force to size middle- and bottom-story hold-down connectors.

**Reason:** Table R602.10.3(3): This proposal is editorial. Table symbols are modified to clarify intent and for consistency with modifications proposed to Table R602.10.6.5, as discussed in the reason for Part 3. A footnote is added to call the designer’s attention to the existing limitation.

Table R602.10.3(4): This proposal is editorial. A footnote is added to call the designer’s attention to the existing limitation in a location that benefits the user.
Table R602.10.6.5: This is an editorial clarification of existing provisions. The proposed modification to the table symbols clarifies that in SDC D2 these bracing provisions are only applicable to one- and two-story dwellings. This proposal is prompted by comment from the Brick Industry Association that the table may be mistakenly interpreted to permit prescriptive bracing of dwellings with veneer in the second and third stories of three story buildings. The original intent and justification for the provisions, however, only permitted use with one- and two-story dwellings, as demonstrated by the historical description that follows.

The BV-WSP bracing provisions were brought into the IRC in the 2006 Edition as a collaborative effort involving BIA and FEMA/BSSC-CRSC, among others. The justification included engineering calculations to support the bracing requirements and hold-down forces. Because of this basis and the seismic forces calculated, prescriptive bracing requirements in SDC D2 were limited to one- and two-story dwellings. The proposed modification will make clear this intent.

The following is as adopted in the 2006 IRC.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.

- Cripple walls are not permitted in Seismic Design Categories D₀, D₁, and D₂.
- Applies to exterior and interior braced wall lines.
- Hold down force is minimum allowable stress design load for connector providing uplift from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single story hold down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained. [See Figure R602.12].
- Where hold down connectors from stories above align with stories below, use cumulative hold down force to size middle and bottom story hold down connectors. [See Figure R602.12].

Presentation of the information was editorially modified by code change RB107-09/10 to the current presentation. The proposal was AM at the committee hearings and was on the consent agenda for the public comment hearings.
The reason statement of RB107-09/10 indicates that (with minor noted exceptions) it is intended to be an editorial code change. There was no discussion of intent to permit three story BV-WSP dwellings in SDC D₂.
Reason: Last cycle, the special wall bracing requirements for wood-framed buildings with stone or masonry veneer were moved from Section R703.7 to Section R602.12, so they would follow the rest of the wall bracing provisions. This was a substantial clarification to the code. However, with the changes introduced by the Ad-Hoc Wall Bracing Committee, the committee of seismic adjustment factors, bracing methods, and other improvements, an opportunity now exists to further simplify matters, bring the special veneer provisions into the main bracing section, and remove duplicated text. As such, this proposal implements the following changes:

1. A new intermittent method, BV-WSP, is defined. The basic sheathing and nailing requirements are relocated from Section R602.12.3 to a new row in Table R602.10.2. The hold-down requirement is relocated from Section R602.12.1.3 to Section R602.10.1.4. The reference to Table R602.3(5), the wood stud table, is no longer needed. Once this language was moved to Section R602, that table automatically governs.
2. A new exception is added to R602.10.1.2, replacing the original charging language for R602.12. The remaining SDC-specific requirements are incorporated into new Section R602.10.1.5.
3. A reference to Method BV-WSP is added to the high-seismic end panel location requirements of Section R602.10.1.4.1. The duplicate language in Section R602.12.1.2 is no longer required and can be deleted.
4. The adjustments for SDC A, B, and C are inserted directly into Table R602.10.1.2(3), the seismic adjustment factor. Table R602.12(1) is no longer required and can be deleted.
5. A reference to Method BV-WSP is added to the minimum braced wall panel length requirements of Section R602.10.3 and to Table R602.10.3.1. The duplicate language in Section R602.12.1.4 is no longer required and can be deleted.
6. A new Section R602.10.3.5 is added for the new Method BV-WSP. The requirements of R602.12, R602.12.1, and R602.12.1.1 are moved into the new section. A subsection, R602.10.3.5.1, is defined for the length of bracing, with language similar to Section R602.10.1.2. Figure R602.12 is moved to the new section.
7. Table R602.12(2) is moved to Section R602.10.3.5 and revised to convert the percentages to lengths, similar to Table R602.10.1.2(2).
8. Figure R602.12 is replaced by new Figure R602.10.3.5, which provides a number of clarifications regarding the location and type of hold-down devices.
9. Since BV-WSP is now defined as its own separate intermittent bracing method, Sections R602.10.1.5 and R602.12.1.6 are no longer needed and can be deleted.

This change represents an editorial relocation and reorganization of the special wall bracing provisions for structures with veneer. Section R602.12 is effectively deleted and all of its provisions incorporated under the scope of Section R602.10. While the intent was purely editorial, two minor technical changes were made. First, the previous provisions do not indicate whether a gypsum board finish is required. But, Method BV-WSP is essentially a fully-restrained engineered shear wall segment, and typically the effect of finishes is not incorporated in such designs. Thus, we believe the interior finish is not required, and amend Section R602.10.2.1 accordingly. Second, in the new Table R602.10.3.5, which replaces Table R602.12(2), the hold-down requirements were combined as part of the reformatting to make the table look like Table R602.10.1.2(2). In the process, the 3200 lb and 5100 lb hold-downs for a bottom of two-story are now required to be 3500 lb and 5400 lb respectively. However, this does not change the actual required strap or hold-down size which a user would select from a connector manufacturer's catalog.

Cost Impact: The code change proposal will not increase the cost of construction.

Proposal # 4579
Proponent: Rick Allen, International Staple, Nail and Tool Association, representing International Staple, Nail and Tool Association (rallen@isanta.org)

2018 International Residential Code

Revise as follows:

TABLE R602.10.4
BRACING METHODS

Portions of table not shown remain unchanged.

<tr>
<td></td>
<td></td>
<td></td>
<td>gage staples</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>6&quot; o.c. on all framing members</td>
</tr>
</tbody>
</table>

Reason: ASTM F1667-18 requires that when gage is used as a diameter for nails, a decimal equivalent must also be shown. This requirement was put in place because of the multiple and conflicting wire gage tables that are used in the manufacturing of nails.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal will not change the cost of production. It only provides clarification required by ASTM F1667-18
Proponent: Randy Shackelford, P.E., Simpson Strong-Tie Co., representing Simpson Strong-Tie Co. (rshackelford@strongtie.com)

2018 International Residential Code

R602.10.6.2 Method PFH: Portal frame with hold-downs. Method PFH braced wall panels shall be constructed in accordance with Figure R602.10.6.2.

Revise as follows:
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**FIGURE R602.10.6.2**
**METHOD PFH—PORTAL FRAME WITH HOLD-DOWNS**

**Reason:** The purpose of this code change is to caution the user regarding the installation of the strap-type hold-down for the Method PFH Portal Frame braced wall panel. Method PFH requires a 3600 pound embedded strap-type hold-down at each edge to restrain the frame against overturning. The drawing gives the impression that the holdown can be installed right at the edge of the concrete. However, the two major manufacturers of this type of hold-down, Simson Strong-Tie and USP/MiTek, both require that the holdown be installed a minimum of 1/2 inch from the edge of the concrete in order to achieve the published allowable loads. There may be other manufacturers that have different required edge distances, though, so instead of specifying the 1/2 inch it was just modified to require the Manufacturer's Required Edge Distance.

Here is the installation detail from Simpson Strong-Tie showing the required edge distance.

Here is the installation footnotes from the MiTek Evaluation Report for the Strap-Type Hold-down

1) Predrilled holes are not required.
2) Wood thickness shall be no less than 3” (2 - 2x members).
3) Corner strap location implies that the distance from the corner of the wall to the edge of the strap is no less than 1/2”.
4) Middle strap location implies that the minimum distance from the corner of the wall to the centerline of the strap is no less than 1.5 times the embed
5) For edge distances between 1/2” and 1.5 x IE calculate loads using straight line interpolation.
6) Minimum anchor spacing for full capacity is 2 x IE. For spacing less than that reduce capacity proportionally.
7) Allowable tension loads are for Doug-Fir, Southern Pine, Spruce-Pine-Fir and Hem Fir.
8) The strap should be fastened with nails starting from lowest pair of nail holes and working up towards the top of the strap. In many cases, not all
   nail holes are needed to be filled.
9) Minimum concrete strength f’c = 2,500 psi.
10) Minimum 1-#4 rebar shall be installed in the shear cone.
11) Deflection at highest allowable loads for installation over wood double studs are as follows:
   LSTAD8 = 0.037”, STAD8 = 0.048”, STAD10 = 0.059”, STAD14 = 0.122”.
12) **NAILS:** 16d sinkers are 0.148” dia. x 3-1/4” long. 10d common (0.148” dia. x 3” long) nails may be substituted with no load reduction.

**Bibliography:** Simpson Strong-Tie Co., Inc. ICC-Es Evaluation Report number ESR-2920
MiTek USA, Inc. ICC-ES Evaluation Report number ESR-2787

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The main impact of this is to ensure that if a Method PFH braced wall panel is used, the strap style hold down is located at least 1/2” from the corner, in accordance with the manufacturer’s instructions. If that forces the
builder to build their foundation 1/2" wider, then it could increase costs. If the builder just moves the garage
door location over by 1/2", though, then there is no impact on cost. If the builder installs the strap right next to
the edge of the foundation, and then is failed on inspection because the hold down is not installed per the
manufacturer's instructions, then there is a large increase in cost for the builder to fix the issue.

Proposal # 5108

RB206-19
RB207-19
IRC®: R602.10.6.4, R602.12.6.2

Proponent: Ralph Leyva, representing APA- The Engineered Wood Assoc (ralph.leyva@apawood.org); Borjen Yeh, APA - The Engineered Wood Association, representing APA - The Engineered Wood Association (borjen.yeh@apawood.org)

2018 International Residential Code
Revise as follows:

R602.10.6.4 Method CS-PF: Continuously sheathed portal frame. Continuously sheathed portal frame braced wall panels shall be constructed in accordance with Figure R602.10.6.4 and Table R602.10.6.4. The number of continuously sheathed portal frame panels in a single braced wall line shall not exceed four.

R602.12.6.2 Method CS-PF. Braced wall panels constructed as Method CS-PF in accordance with Section R602.10.6.4 shall be permitted where all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-PF panel shall equal 0.75 bracing units. Not more than four CS-PF panels shall be permitted on all segments of walls parallel to each side of the circumscribed rectangle. Segments of wall that include a Method CS-PF panel shall meet the requirements of Section R602.10.4.2.

Reason: This provision first appeared in the 2009 IRC and was based on full-scale, whole-house testing conducted at the APA Research Center in Tacoma, Washington. In testing conducted in 2007 (APA Report T2007-73, https://www.apawood.org/data/tsd-links/t2007-73-3d-house-test-results.pdf), a single wall was tested with 9 each 16-inch long CS-PFs in line for a total braced length of 12 ft. This testing was compared with 3 each 48-inch long Type WSP walls, also a total length of 12 ft. The results of this testing showed the CS-PF wall had a significantly higher strength at 2.5% drift and stiffer than the equivalent length Type WSP walls. The evidence was considered sufficient by the then Wall Bracing Ad Hoc Committee to support its inclusion in the 2009 IRC, with the limitation of 4 CS-PFs in any single wall even though the testing was conducted with 9 CS-PFs. This provision was added because the portal frame concept was quite original and the committee wanted a little more experience before expanding the number of permitted CS-PFs. Fast forward to 2019 and we are writing provisions for the 2021 IRC in which the current limitation of a maximum of 4 CS-PFs per wall will have been in the IRC for 10 years and can no longer be considered as original. During the last decade, APA has not been apprised of any problems associated with this provision. It is inconceivable that there will be more than 9 CS-PFs in a given wall line within the scope of the IRC. As a result, APA proposes to remove the limitation for the number of CS-PFs.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change proposal will not add cost to the design and construction of a new home.

Proposal # 5532

RB207-19
2018 International Residential Code

Revise as follows:

**R602.10.6.5 Wall bracing for dwellings with stone and masonry veneer in Seismic Design Categories D₀, D₁, and D₂.** Townhouses in Seismic Design Categories D₀, D₁, and D₂ with stone or masonry veneer exceeding the first-story height shall be designed in accordance with accepted engineering practice. One- and two-family dwellings in Seismic Design Category D₂ exceeding two stories and having stone or masonry veneer shall be designed in accordance with accepted engineering practice.

Where stone and masonry veneer are installed in accordance with Section R703.8, wall bracing on exterior **braced wall lines** and **braced wall lines** on the interior of the building, backing or perpendicular to and laterally supporting veneered walls shall comply with this section.

Where dwellings in Seismic Design Categories D₀, D₁, and D₂ have stone or masonry veneer installed in accordance with Section R703.8, and the veneer does not exceed the first-story height, wall bracing shall be in accordance with Section R602.10.3.

Where detached one- or two-family dwellings in Seismic Design Categories D₀, D₁, and D₂ have stone or masonry veneer installed in accordance with Section R703.8, and the veneer exceeds the first-story height, wall bracing at exterior **braced wall lines** and **braced wall lines** on the interior of the building shall be constructed using Method BV-WSP in accordance with this section and Figure R602.10.6.5. Cripple walls shall not be permitted, and required interior **braced wall lines** shall be supported on continuous foundations.

Where detached one- or two-family **dwellings** in Seismic Design Categories D₀, D₁, and D₂ have exterior veneer installed in accordance with Section R703.8 and are braced in accordance with Method WSP or CS-WSP, veneer shall be permitted in the second story in accordance with Item 1 or 2, provided that the **dwelling** does not extend more than two stories above grade plane, the veneer does not exceed 5 inches (127 mm) in thickness, the height of veneer on gable-end walls does not extend more than 8 feet (2438 mm) above the bearing wall top plate elevation, and the total length of **braced wall panel** specified by Table R602.10.3(3) is multiplied by 1.2 for each first- and second-story **braced wall line**.

1. The total area of the veneer on the second-story exterior walls shall be permitted to extend up to 25 percent of the occupied second floor area.
2. The veneer on the second-story exterior walls shall be permitted to cover one side of the **dwelling**, including walls on bay windows and similar appurtenances within the one dwelling side.

Townhouses in Seismic Design Categories D₀, D₁, and D₂ with stone or masonry veneer exceeding the first-story height shall be designed in accordance with accepted engineering practice.

**Reason:** This proposal provides editorial clarification of existing provisions. Townhouses exceeding the first
story are currently scoped out of the R602.10.6.5 provisions permitting veneer in SDC D0, D1, and D2; relocating this limitation to the front of the section places it where it is of most benefit to the designer. Similarly, a sentence is added communicating the current Table R602.10.6.5 limitations for veneer on one- and two-family dwellings that exceed two stories in SDC D2, again to clearly communicate scope limitations to the designer.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
No cost impact. This is an editorial clarification of the intent of current provisions.
RB209-19

IRC: TABLE R602.10.3(4), TABLE R602.10.4, R602.10.6.5, Figure R602.10.6.5, R602.10.6.5.1, R602.10.6.5.2 (New), R602.10.6.5.3 (New), R602.10.6.5.4 (New)

Proponent: Randy Shackelford, Simpson Strong-Tie Co., representing Simpson Strong-Tie Co. (rshackelford@strongtie.com)

2018 International Residential Code

R602.10.6 Construction of Methods ABW, PFH, PFG, CS-PF and BV-WSP. Methods ABW, PFH, PFG, CS-PF and BV-WSP shall be constructed as specified in Sections R602.10.6.1 through R602.10.6.5.

Revise as follows:

R602.10.6.5 Wall bracing for dwellings with stone and masonry veneer in Seismic Design Categories D0, D1 and D2. Where stone and masonry veneer are installed in accordance with Section R703.8, wall bracing on exterior braced wall lines and braced wall lines on the interior of the building, backing or perpendicular to and laterally supporting veneered walls shall comply with this section.

Where dwellings in Seismic Design Categories D0, D1 and D2 have stone or masonry veneer installed in accordance with Section R703.8, and the veneer does not exceed the first-story height, wall bracing shall be in accordance with Section R602.10.3. Where detached one- or two-family dwellings in Seismic Design Categories D0, D1 and D2 have stone or masonry veneer installed in accordance with Section R703.8, and the veneer exceeds the first-story height, wall bracing at exterior braced wall lines and braced wall lines on the interior of the building shall be constructed using Method BV-WSP in accordance with this section and Figure R602.10.6.5. Cripple walls shall not be permitted, and required interior braced wall lines shall be supported on continuous foundations. Where detached one- or two-family dwellings in Seismic Design Categories D0, D1 and D2 have exterior veneer installed in accordance with Section R703.8 and are braced in accordance with Method WSP or CS-WSP, veneer shall be permitted in the second story in accordance with Item 1 or 2, provided that the dwelling does not extend more than two stories above grade plane, the veneer does not exceed 5 inches (127 mm) in thickness, the height of veneer on gable-end walls does not extend more than 8 feet (2438 mm) above the bearing wall top plate elevation, and the total length of braced wall panel specified by Table R602.10.3(3) is multiplied by 1.2 for each first- and second-story braced wall line.

1. The total area of the veneer on the second-story exterior walls shall be permitted to extend up to 25 percent of the occupied second floor area.
2. The veneer on the second-story exterior walls shall be permitted to cover one side of the dwelling, including walls on bay windows and similar appurtenances within the one-dwelling side.

Townhouses in Seismic Design Categories D0, D1 and D2 with stone or masonry veneer exceeding the first-story height shall be designed in accordance with accepted engineering practice.

Add new text as follows:

R602.10.6.5.1 Veneer on First Story Only. Where dwellings in Seismic Design Categories D0, D1 and D2 have stone or masonry veneer installed in accordance with Section R703.8, and the veneer does not exceed the first-story height, wall bracing shall be in accordance with Section R602.10, exclusive of this section.

R602.10.6.5.2 Veneer Exceeding First Story Height. Where detached one- or two-family dwellings in Seismic Design Categories D0, D1 and D2 have stone or masonry veneer installed in accordance with Section R703.8, and the veneer exceeds the first-story height, wall bracing at exterior braced wall lines and braced wall lines on the interior of the building shall be constructed using Method BV-WSP in accordance with this section and...
Figure R602.10.6.5.2. Cripple walls shall not be permitted, and required interior *braced wall lines* shall be supported on continuous foundations.
R602.10.6.5.3 Limited Veneer Exceeding First Story Height. Where detached one- or two-family dwellings in Seismic Design Categories D0, D1, and D2 have exterior veneer installed in accordance with Section R703.8 and brick veneer installed above the first story height meets the following limitations, bracing in accordance with Method WSP or CS-WSP shall be permitted provided the total length of braced wall panel specified by Table R602.10.3(3) is multiplied by 1.2 for each first- and second-story braced wall line.

1. The dwelling does not extend more than two stories above grade plane.
2. The veneer does not exceed 5 inches (127 mm) in thickness.
3. The height of veneer on gable-end walls does not extend more than 8 feet (2438 mm) above the bearing wall top plate elevation.
4. Where veneer is installed on multiple walls above the first story, the total area of the veneer on the second-story exterior walls shall not exceed 25 percent of the occupied second floor area.
5. Where the veneer is installed on one entire second-story exterior wall, including walls on bay windows and similar appurtenances, brick veneer shall not be installed on any of the other walls on that floor.

R602.10.6.5.4 Townhouses. Townhouses in Seismic Design Categories D0, D1, and D2 with stone or masonry veneer exceeding the first-story height shall be designed in accordance with accepted engineering practice.

Revise as follows:
R602.10.6.5.1 Length of bracing. The length of bracing along each braced wall line shall be the greater of that required by the ultimate design wind speed and braced wall line spacing in accordance with Table R602.10.3(1) as adjusted by the factors in Table R602.10.3(2) or the seismic design category and braced wall line length in accordance with either Table R602.10.6.5 when using Method BV-WSP, or Table R602.10.3(3) as adjusted by the factors in Table R602.10.3(4) when using Method WSP or CS-WSP. Angled walls shall be permitted to be counted in accordance with Section R602.10.1.4, and braced wall panel location shall be in accordance with Section R602.10.2.2. Spacing between braced wall lines shall be in accordance with Table R602.10.1.3. The seismic adjustment factors in Table R602.10.3(4) shall not be applied to the length of bracing determined using Table R602.10.6.5, except that the bracing amount increase for braced wall line spacing greater than 25 feet (7620 mm) in accordance with Table R602.10.1.3 shall be required. The minimum total length of bracing in a braced wall line, after all adjustments have been taken, shall be not less than 48 inches (1219 mm) total.

### TABLE R602.10.6.5

**R602.10.6.5.5**  
**METHOD BV-WSP WALL BRACING REQUIREMENTS**

Portions of table not shown remain unchanged.

<table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.  
NP = Not Permitted.

NA = Not Applicable.

a. Hold-down force is minimum allowable stress design load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single-story hold-down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained.

b. Where hold-down connectors from stories above align with stories below, use cumulative hold-down force to size middle- and bottom-story hold-down connectors.

Reason: The purpose of this change is to clarify wall bracing of dwellings that have brick veneer. Last cycle a section was added to permit limited brick veneer on the second story without triggering the use of BV-WSP, but there were conflicts in how this was to be applied. The main goal is to clarify this application. Table R602.10.3(4) is proposed to be modified to refer to Section R602.10.6.5.3, which states when methods WSP and CS-WSP can be used to brace brick veneer, instead of Table R602.10.6.5, which gives bracing amounts for Method BV-WSP bracing. The assumption I make here is that the intent was that when this limited brick veneer was installed, then the bracing lengths in Table R602.10.3(3) were to be used for the WSP and CS-WSP bracing, adjusted by the 1.2 factor, and not the BV-WSP bracing amounts.

Section R602.10.6.5 is broken into several sub-sections in order to make it easier to read and use. Except for clarifying the bracing length to use for WSP and CS-WSP, there is no intent to make any substantive changes, just re-wording. The long paragraph of limitations in new R602.10.6.5.3 is broken into a list for clarification and ease of use.

Finally, Section R602.10.6.5.5 (formerly R602.10.6.5.1) is clarified along the lines stated above to specify which table to use to calculate the required length of bracing for each permitted method. If this is not changed, then
the WSP and CS-WSP would be required to use the BV-WSP bracing amounts in Table R602.0.6.5 for seismic bracing.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The main intent of this code change is to clarify the section and not make any technical changes.

Proposal # 5197

RB209-19
**2018 International Residential Code**

Revise as follows:

<table>
<thead>
<tr>
<th>SEISMIC DESIGN CATEGORY</th>
<th>STORY</th>
<th>BRACED WALL LINE LENGTH (FEET)</th>
<th>SINGLE-STORY HOLD-DOWN FORCE (pounds)*</th>
<th>CUMULATIVE HOLD-DOWN FORCE (pounds)*</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>10</td>
<td>20</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Total Length (feet) of Braced Wall Panels Required Along each Braced Wall Line</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.

NP = Not Permitted.

NA = Not Applicable.

a. Hold-down force is minimum allowable stress design load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single-story hold-down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained.

b. Where hold-down connectors from stories above align with stories below, use cumulative hold-down force to size middle- and bottom-story hold-down connectors.

c. Interpolation between braced wall lengths is permitted.

**Reason:** Table and section does not state one way or another on interpolation and needs clarification. Based on the way the table was developed, the interpolation should be permitted.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal permits interpolation between specified braced wall lengths and will not increase the construction cost.

---

Proposal # 4693

RB210-19
R602.10.10.1 Cripple wall bracing for Seismic Design Categories D0 and D1 and townhouses in Seismic Design Category C. In addition to the requirements in Section R602.10.10, cripple wall bracing shall comply with the following:

1. Cripple wall sheathing shall be limited to methods WSP and CS-WSP.
2. Cripple walls in one-story dwellings shall be braced with the length and method of bracing required for the first story of a two-story dwelling.
3. Cripple walls in two-story dwellings shall be braced with the length and methods of bracing required for the first story of a three-story dwelling.
4. Cripple walls in three-story dwellings shall be braced with the length and the method of bracing required for this first story of a three-story dwelling, further multiplied by 1.5.
5. The multiplication factor of 1.15 in Section R602.10.10 is not required.
6. Where gypsum wall board is not used on the inside of the cripple wall bracing, the length adjustments for the elimination of the gypsum wallboard, or equivalent, shall be applied as indicated in Tables R602.10.3(2) and R602.10.3(4) to the length of cripple wall bracing required.
7. The distance between adjacent edges of braced wall panels for cripple walls along a braced wall line shall be 14 feet (4267 mm) maximum.
8. Where braced wall lines at interior walls are not supported on a continuous foundation below, the adjacent parallel cripple walls, where provided, shall be braced with Method WSP or Method CS-WSP in accordance with Section R602.10.4. The have the length of bracing required in accordance with Table R602.10.3(3) for the cripple walls Items 2 through 4 and shall be further multiplied by 1.5. Where the cripple walls do not have sufficient length to provide the required bracing, the spacing of panel edge fasteners shall be reduced to 4 inches (102 mm) on center and the required bracing length adjusted multiplied by 0.7. If the required length can still not be provided, the cripple wall shall be designed in accordance with accepted engineering practice.

Reason: This proposal requires the use of wood structural panel (plywood or OSB) sheathing on cripple walls for townhouses in SDC C and all dwellings in SDC D0 and D1. This extends a requirement already in place for dwellings in SDC D2. In addition, the length of sheathing is specified based on the cripple wall being an additional story below the occupied stories. This is consistent with the seismic demand that the cripple walls resist.

This change is proposed because recent studies have reconfirmed the need for and benefit of providing wood structural panel sheathing on cripple walls in regions of moderate to high seismic hazard. As part of work contributing to the FEMA P-1100 (Vulnerability-Based Seismic Assessment and Retrofit of One- and Two-Family Dwellings Volume 1 - Prestandard), it was identified that the use of wood structural panel sheathing is needed for cripple walls in light-frame dwellings in order to meet the seismic performance objectives targeted by the residential and building codes. This is believed to be largely due to there being significantly less total wall length.
and little or no finish material contribution to seismic bracing at the cripple wall level. As a result, cripple walls subject to earthquake loading must withstand higher shear forces and significantly greater horizontal displacement levels than the stories above. The need for and improvement provided with the addition of wood structural panel cripple wall bracing was demonstrated in numerical studies by the probability of collapse reducing by one-half to two-thirds with the addition of wood structural panel sheathing. Given that the cost of providing wood structural panel sheathing is estimated to be less than one percent of the construction cost of the home, the benefit significantly outweighs the cost.

**Cost Impact:** The code change proposal will increase the cost of construction. This will modestly increase the cost of dwellings in moderate and high seismic hazard regions by requiring the use of wood structural panel sheathing on the cripple walls. This is estimated to be less than one percent of the construction cost of the dwelling.
RB212-19 Part I

PART I — IRC: R602.13 (New)

PART II — IECC: R402.1.6 (New), TABLE R402.1.2

Proponent: Vladimir Kochkin, Home Innovation Research Labs, representing Home Innovation Research Labs (vkochkin@homeinnovation.com); Patricia Gunderson, Home Innovation Research Labs, representing Home Innovation Research Labs (pgunderson@homeinnovation.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IRC-BUILDING COMMITTEE. PART II WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

2018 International Residential Code

Add new text as follows:

R602.13 Extended Plate Wall. Extended plate wall (EPW) construction shall comply with all applicable provisions of Sections R602.1 through R602.12 as modified by the provisions of Section R602.13. EPW shall be limited to Seismic Design Categories A, B, and C for detached one- and two-family dwellings and to Seismic Design Categories A and B for townhomes.

R602.13.1 Framing. The 2x6 top and bottom plates and 2x4 studs shall be used in accordance with Figures R602.13.1(1) and R602.13.1(2). A single top plate shall not be permitted.
2x6 DOUBLE TOP PLATE

HEADER PER SECTION R602.7 OR R602.13.5

WINDOW OPENING

WOOD STRUCTURAL PANEL SHEATHING

2x4 STUDS/CAVITY INSULATION

FOAM PLASTIC INSULATING SHEATHING

2x6 BOTTOM PLATE

2x6 DOUBLE TOP PLATE
Figure R602.13.1(1)
Extended Plate Wall (EPW) System, Section View
R602.13.2 Wood structural panel sheathing. Wood structural panel sheathing with a minimum nominal thickness of 7/16-inch (11 mm) shall be installed vertically and attached to wall plates and studs per Table R602.13.2 and Figure R602.13.1(2). The vertical joints between adjacent wood structural panels shall occur only at framing members. Where used as part of wall bracing, each wood structural panel shall be continuous, without horizontal joints between the extended top and bottom plates.

**TABLE R602.13.2.**
Sheathing Fastener Requirements for EPW

<table>
<thead>
<tr>
<th>Minimum Nail Length and Diameter</th>
<th>Maximum Fastener Spacing</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>At Perimeter of Wood Structural Panels (inches)</td>
</tr>
<tr>
<td>No. 37 Power-tool Driven Common Nail (3-1/2&quot; x 0.131&quot;)</td>
<td>3 O.C.</td>
</tr>
<tr>
<td>16d Box Nail (3-1/2&quot; x 0.135&quot;)</td>
<td>3 O.C.</td>
</tr>
</tbody>
</table>

For SI: 1-inch = 25.4 mm

a. Where wood structural panel nominal thickness exceeds 1/2 inch (13 mm), the minimum nail length shall be increased by 1/4 inch (6 mm).

b. At top and bottom plates where the wood structural panel is in direct contact with the framing, 8d common nail (2-1/2" x 0.131") shall be permitted.
c. Full round head nail with minimum head diameter of 0.281 inches (7 mm).

d. Nails are in accordance with ASTM F1667.

**R602.13.3 Wall bracing.** Wall bracing for EPW shall be in accordance with the requirements for WSP or CS-WSP or CS-G bracing methods in Section R602.10 except the sheathing fasteners shall be in accordance with Table R602.13.2.

**R602.13.3.1 Simplified wall bracing.** With the exception of Section R602.12.2 Item 2, provisions of Section R602.12 shall be applicable to the EPW. The fastening schedule for wood structural panels shall be in accordance with Table R602.13.2.

**R602.13.4 Rim joist.** Sawn 2x lumber or engineered wood rim board shall be used to construct rim joists. Engineered wood rim board shall be in compliance with Section R602.1.7. The minimum bearing length requirements for the floor joists shall be satisfied or joists shall be supported with metal hangers. Rim joist (band joist) supporting an EPW shall be in accordance with one of the following methods.

1. A double member rim joist installed flush to the exterior face of the wall in accordance with Figure R602.13.4(1). The thickness of individual rim joist members shall not be less than 1-1/2 inches (38 mm).
2. A double member rim joist recessed by 1 inch (25 mm) from the exterior face of the wall in accordance with Figure R602.13.4(2). The thickness of individual rim joist members shall not be less than 1 inch (25 mm). Foam plastic insulative sheathing shall be installed in the 1 inch (25 mm) recess.
3. Approved engineered design.
Figure R602.13.4(1)
Rim Joist Construction for EPW – Double Member
R602.13.5 Rim joist used as rim header. Wood rim boards, or band joists, that serve as rim board headers shall be constructed in accordance with Section R602.7.2.

R602.13.6 Foam plastic insulating sheathing. Foam plastic insulating sheathing (FPIS) with a total thickness of 2 inches (51 mm) shall be installed between top and bottom plates directly to the exterior surface of studs and flush with the 2x6 top and bottom plates. FPIS shall comply with ASTM C578 or ASTM C1289, with a minimum compressive strength of 15 psi. FPIS shall be permitted to be installed in one or more layers.

R602.13.7 Wall coverings. Interior and exterior coverings and wall finishes shall be in accordance with all applicable provisions of Sections R701 through R703 as modified by the provisions of Sections R602.13.7.1 and
R602.13.7.2 Vapor retarder. A vapor retarder on the interior side of the EPW frame shall be in accordance with Section R702.7. Where a Class III interior vapor retarder is used in accordance with Table R702.7.1, EPW shall be designated as a 2x4 wall with continuous insulation and, in Climate Zones 4, 5, 6, 7, and 8, the foam plastic insulating sheathing layer including any facers or surface film shall have a water vapor permeance of less than or equal to 1.5 perms.

R602.13.7.2 Cladding attachment. Cladding shall be specified and installed in accordance with Section R703 and one of the following:

1. Table R703.3.3 for siding attachment to wood structural panels only.
2. Table R703.8.4(2) for brick tie-spacing and attachment to wood structural panels only.
3. Fastening schedule and fasteners as required by Table R703.3.(1), except fastener length shall be selected to meet or exceed the minimum required penetration into framing.

R602.13.8 Uplift connections. Where roof uplift tie-downs are selected in accordance with Section R802.11, the roof tie-downs shall be fastened to either side of the double top plate or, if required to be fastened to studs, shall be installed from the interior face of the wall in accordance with manufacturer’s installation instructions. Where uplift forces determined in accordance with R602.3.5 require approved uplift connectors between floors or between foundation and the floor, these uplift connectors shall not rely on wood structural panel sheathing for resisting roof wind uplift forces.

Proposal # 4671

RB212-19 Part I
2018 International Energy Conservation Code

Add new text as follows:

R402.1.6 Extended Plate Wall (EPW). EPW wall systems constructed in accordance with all applicable provisions of Sections R602.1 through R602.13 of the International Residential Code shall be considered to be in compliance with continuous insulation provisions of Table R402.1.2. For use with the prescriptive minimum insulation requirements, the foam plastic insulating sheathing layer installed outboard of the studs and the cavity insulation shall be in accordance with the required levels of insulation specified in Table R402.1.2.

</table>

NR = Not Required. For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Where insulation is installed in a cavity that is less than the label or design thickness of the insulation, the installed R-value of the insulation shall be not less than the R-value specified in the table.

b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration.

Exception: In Climate Zones 1 through 3, skylights shall be permitted to be excluded from glazed fenestration SHGC requirements provided that the SHGC for such skylights does not exceed 0.30.

c. “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation on the interior of the basement wall. “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. Alternatively, compliance with “15/19” shall be R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home.
d. R-5 insulation shall be provided under the full slab area of a heated slab in addition to the required slab edge insulation $R$-value for slabs, as indicated in the table. The slab edge insulation for heated slabs shall not be required to extend below the slab.

e. There are no SHGC requirements in the Marine Zone.

f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.

g. Alternatively, insulation sufficient to fill the framing cavity and providing not less than an $R$-value of R-19.

h. The first value is cavity insulation, the second value is continuous insulation. Therefore, as an example, “13+5” means R-13 cavity insulation plus R-5 continuous insulation.

i. Mass walls shall be in accordance with Section R402.2.5. The second $R$-value applies where more than half of the insulation is on the interior of the mass wall.

j. EPW wood-frame wall system utilizing foam plastic and cavity insulation equal to or exceeding the prescribed R-values shall satisfy the prescriptive minimum insulation requirements for CZ 3-8.
**2018 International Residential Code**

**Revise as follows:**

**R608.1 General.** Exterior concrete walls shall be designed and constructed in accordance with the provisions of this section or in accordance with the provisions of PCA 100, or ACI 318, or ACI 332. Where PCA 100, ACI 318, ACI 332 or the provisions of this section are used to design concrete walls, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the jurisdiction having authority.

**Reason:** This change updates the exterior concrete wall construction section, R608.1, by including a reference to ACI 332 Residential Code Requirements for Structural Concrete. ACI 332 addresses the design and construction concrete basement or foundation walls constructed with removable forms or with flat insulating concrete forms. ACI 332 is already a referenced standard in section R404.1.3 of the 2018 IRC which also deals with the design of concrete foundation walls.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. It simply puts in a reference to a standard that was overlooked.
R609.1 General. This section prescribes performance and construction requirements for exterior windows and doors installed in walls. Windows and doors shall be installed and flashed anchored in accordance with the fenestration manufacturer’s written instructions. Section R609.7. Window and door openings shall be flashed in accordance with Section R703.4. Written installation Installation instructions shall be provided by the fenestration manufacturer for each window or door.

Reason: The long standing intent of Section R609 is to provide the appropriate performance and construction requirements for window and door products, and anchoring requirements with respect to the installation of them. As the general provision for Section R609, R609.1 should make that clear and for further clarification, make clear that flashing requirements for the window and door opening are provided in Chapter 7 Wall Coverings where they belong and manufacturers are still required to provide installation instructions. As currently written, the inclusion of flashing requirements in this section is not necessary and more importantly conflicts with the provisions of Section R703.4 which does not restrict builders from using other proper flashing installation methods in addition to those included in the manufacturer's instructions when those instructions may not cover a particular installation aspect/s. This proposal corrects that and brings the general provisions of R609.1 back in-line with the intent of Section R609 on the whole by clarifying anchoring must comply with Section R609.7 and flashing of the opening with Section R703.4. The requirement that manufacturers must provide installation instructions remains and more clearly reflects how installation instructions are being provided by manufacturers.

Cost Impact: The code change proposal will decrease the cost of construction

This amendment will reduce the cost of construction when alternatives to the flashing instructions provided by the manufacturer are needed or preferred by the builder because of project specific conditions. Section R703.4 allows the builder to use alternative, code compliant methods under those circumstances. If the flashing provisions of this section are enforced over the flashing provisions of section R703.4, the manufacturer would need to develop project specific alternatives which is costly, results in construction delays, and not practical.
RB215-19
IRC: R609.4.1 (New)

Proponent: T. Eric Stafford, representing Insurance Institute for Business and Home Safety
testafford@charter.net

2018 International Residential Code

R609.4 Garage doors. Garage doors shall be tested in accordance with either ASTM E330 or ANSI/DASMA 108, and shall meet the acceptance criteria of ANSI/DASMA 108.

Add new text as follows:

R609.4.1 Garage door labeling. Garage doors shall have a permanent label identifying the garage door manufacturer, the garage door model/series number, the positive and negative design wind pressure rating, the installation instruction drawing reference number, and the applicable test standard.

Reason: This proposal is one of several that are addressing labeling of critical components of the building envelope. The primary purpose of this code change is to require that garage doors have a permanent label that provides a way for building owners, homeowners, and others to be able to determine their performance characteristics after the building has been occupied. The 2018 IRC does not require any type of label for garage doors. For products that don’t have permanent labels, it becomes nearly impossible for the owner to determine the structural wind load resistance and/or energy efficiency of the garage doors after they’ve occupied the building. This proposal would simply require some type of permanent marking on the garage door indicating the manufacturer and model/series number, and performance characteristics so that the specific performance characteristics could be retrieved at a later date.

This same proposal was submitted for the 2018 IRC but was not approved by the IRC B Committee. However, it was nearly unanimously approved at the final action hearings, but did not get the required majority during the OGVC.

For the past 10-15 years, there has been a push towards considering sustainability in the way our buildings are constructed in this country. If this goal is to be successful and building owners and occupants increasingly want more information about the sustainability of the buildings they occupy, they need to be provided with information needed to determine how critical components are expected to perform in the buildings they use. Garage doors are important components of the building envelope and their performance is critical in preventing wind and water infiltration as well as to maintaining the overall structural integrity of the building.

Some manufacturers already include permanent labels on their products that provide traceability to the manufacture and the product characteristics. The Florida Building Code has required this type of label since the 2007 edition and has continued to require it in subsequent editions. The following is the relevant text from the 6th Edition (2017) Florida Building Code, Residential:

R612.4.1 Garage door labeling. Garage doors shall be labeled with a permanent label provided by the garage door manufacturer. The label shall identify the garage door manufacturer, the garage door model/series number, the positive and negative design pressure rating, indicate impact rated if applicable, the installation instruction drawing reference number, the Florida Product Approval or Miami-Dade Product Approval number if applicable, and the applicable test standards. The required garage door components for an approved garage door assembly may be indicated using a checklist form on the label. If a checklist format is used on the label, the door installer or the garage door manufacturer shall mark the selected components on the checklist that are required to assemble an approved garage door system. The installation instructions shall be provided and available on the job site.
Also, Oklahoma Uniform Building Code Commission Rules in their Appendix Y require that garage doors be wind rated to 135 mph. Having a permanent label will facilitate verification that the right type of garage door is installed.

Another consideration is that insurance incentives are now being offered in some states for homes, new and existing, that comply with certain levels of the Fortified program administered by IBHS. The Fortified program is a set of engineering and building standards designed to help strengthen new and existing homes through system-specific building upgrades to minimum building code requirements that will reduce damage from specific natural hazards. Fortified offers three different levels of designation (bronze, silver, and gold) depending on the extent of the recommended “upgrades” to the building’s wind resistance. To qualify for a designation, the home has to be inspected. Without a permanent label indicating the manufacturer and product model/series number, the performance characteristics often cannot be determined, and certain Fortified designations become difficult or impossible to be given.

Approval of this proposal will assure, going forward, that new or replaced garage doors will be labeled such that building owners and those considering the purchase of buildings with these products will be able to obtain information necessary for determining the expected performance of these critical components of the building envelope.

**Cost Impact:** The code change proposal will increase the cost of construction

Will impact cost for some manufacturers. The code does not currently require a permanent label. However, some garage door manufacturers voluntarily apply a permanent label that identifies the critical performance characteristics. There will be no cost impact to those manufacturers.

</tbody>
</table>

For SI: 1 inch = 25.4 mm.

a. For application without adhesive, a pair of nails spaced not less than 2 inches apart or more than 2\(\frac{1}{2}\) inches apart shall be permitted to be used with the pair of nails spaced 12 inches on center.

b. Screws shall be in accordance with Section R702.3.5.1. Screws for attaching gypsum board or gypsum panel products to structural insulated panels shall penetrate the wood structural panel facing not less than \(\frac{7}{16}\) inch.

c. Where cold-formed steel framing is used with a clinching design to receive nails by two edges of metal, the nails shall be not less than \(\frac{5}{8}\) inch longer than the gypsum board or gypsum panel product thickness and shall have ringed shanks. Where the cold-formed steel framing has a nailing groove formed to receive the nails, the nails shall have barbed shanks or be 5d, 13\(\frac{1}{2}\) gage, 1\(\frac{5}{8}\) inches long, 15\(\frac{1}{64}\)-inch head for 1\(\frac{1}{2}\)-inch gypsum board or gypsum panel product; and...
6d, 13 gage, $1^{7/8}$ inches long, $15/64$-inch head for $5/8$-inch gypsum board or gypsum panel product.

d. Three-eighths-inch-thick single-ply gypsum board or gypsum panel product shall not be used on a ceiling where a water-based textured finish is to be applied, or where it will be required to support insulation above a ceiling. On ceiling applications to receive a water-based texture material, either hand or spray applied, the gypsum board or gypsum panel product shall be applied perpendicular to framing. Where applying a water-based texture material, the minimum gypsum board thickness shall be increased from $3/8$ inch to $1/2$ inch for 16-inch on center framing, and from $1/2$ inch to $5/8$ inch for 24-inch on center framing or $1/2$-inch sag-resistant gypsum ceiling board shall be used.

**Reason:** renaming to "ring shank" from "annular ringed" to be consistent with existing terminology in the code.

For the 5/8" Type X at garage ceiling, the description of a $1^{7/8}$" 6d coated nail does not provide a complete description.

Providing a nail diameter (0.099 inches) and "galvanized" provides a complete description for the nail.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

These changes provide clarification to existing language and will not affect cost

Proposal # 3875
Proponent: Cesar Lujan, representing National Association of Home Builders (clujan@nahb.org); Gary Ehrlich, representing National Association of Home Builders (gehrlich@nahb.org)

2018 International Residential Code

Revise as follows:

R702.7 Vapor retarders. Vapor retarders on the interior side of frame walls shall be installed in accordance with this section. Class I or II vapor retarders are required shall be provided on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where accumulation, condensation, or freezing of moisture or its freezing will not damage the materials.

Add new text as follows:

702.7.1 Class I and II vapor retarders. Class I and II vapor retarders shall not be provided on the interior side of frame walls in Climate Zone 1A, 2A, and portions of Climate Zone 3A south of the warm-humid line.

Reason: The purpose of this code change is to provide appropriate limitations on the use of Class I or II interior vapor retarders in the warm-humid climate zones. The intent of providing a vapor retarder in the wall assembly is to control the migration of moisture from the warm side of the wall assembly to the colder side, where it can condense against colder surfaces and, if trapped within a portion of the wall assembly, cause mold growth or material decay. The existing vapor retarder requirements are intended for colder climates where the most concerning direction of vapor drive is from the warm inside of the house towards the colder outside, occurring during the heating (winter) season. In warmer climates, the direction of concern would be from the warm outside towards the colder inside of the house, occurring during the cooling (summer) season. In the latter case, a vapor retarder on the inside of the wall assembly would prevent the wall from drying inwards and could result in condensation occurring on the interior gypsum board or on the back side of the vapor retarder. Either one could result in mold growth and decay. To minimize the risk of interior vapor retarders being installed where they are not necessary, and could cause issues within the wall, an explicit limitation on interior vapor retarders in the warm-humid climate zones is proposed.

The code change also provides several editorial revisions. A separate section under 702.7 for the Class I and II vapor retarder requirements is created, and new charging language for the entire vapor retarder provisions added. The third exception to providing Class I or II vapor retarders is revised to clarify what the moisture conditions of concern are that need to be evaluated in deciding whether a wall assembly can be exempted from the vapor retarder requirements.

The proposed limitations are consistent with industry guidance from Home Innovation Research Labs, Building Science Corporation, DOE’s Building America program, NAIMA, and others.

Building Science Digest 106, Understanding Vapor Barriers, Building Science Corporation, October 2006 (Revised April 2011).

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change clarifies when interior vapor retarders are not required, and in fact when they should not be provided. If anything, this code change would reduce the cost of construction if interior vapor retarders are currently being installed where they are not necessary, as well as avoiding the potential cost of mitigating moisture issues down the road.
2018 International Residential Code

SECTION R702
INTERIOR COVERING

Revise as follows:

R702.7 Vapor retarders. Class I or II vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4. Installation of a Class I vapor retarder shall comply with all of the following:

1. Be sealed to framing with construction adhesive or equivalent at the top and bottom plates, around window and door openings, and other areas where needed to create a tight seal.
2. Be sealed air tight around utility boxes and other penetrations.
3. Seams in the vapor retarder shall be overlapped at least 6 inches (152 mm) and sealed with compatible sealing tape or equivalent.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.

Reason: I have yet to see manufacture instructions for how to install a class one vapor retarder yet that is what the code relies on. The building science community has studied and reported on the fact that 90 plus percent of the moisture that enters walls or other assemblies is driven there by air leakage not diffusion. If a class one vapor retarder is installed and not sealed to prevent the majority of moisture transport via air leakage then it merely is trapping moisture not fully retarding its ability to enter the cavity. Yes, the barrier can substantially stop vapor diffusion which means that it is not forgiving and will not allow water vapor to diffuse back out of an assembly if it were to get in by other means than diffusion. The requirement to install a vapor retarder is reliant that it is installed correctly not only to stop or reduce vapor diffusion but also moisture that travels with air. Minnesota has realized the reality and dichotomy of this situation and therefore has added some basic installation instruction into their adopted code. The language has been adapted here so as to offer guidance that is needed and missing in the industry.

Cost Impact: The code change proposal will increase the cost of construction
Although this proposal should not increase the cost of construction it is expected that it will slightly since the majority of the country does not enforce proper installation of class one vapor retarders.
**2018 International Residential Code**

Revise as follows:

**R702.7 Vapor retarders.** Class I, II or III vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4.

**Exceptions:**

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.

**R702.7.1 Class III vapor retarders.** Class III vapor retarders shall be permitted where any one of the conditions in Table R702.7.1 is met.

**TABLE R702.7.1**

CLASS III VAPOR RETARDERS

Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>CLIMATEZONE</th>
<th>CLASS III VAPOR RETARDERS PERMITTED FOR:*</th>
</tr>
</thead>
</table>

**R702.7.2 Material vapor retarder class.** The vapor retarder class shall be based on the manufacturer’s certified testing or a tested assembly. The following shall be deemed to meet the class specified:

1. Class I: Sheet polyethylene, on perforated aluminum foil.
2. Class II: Kraft-faced fiberglass batts.
3. Class III: Latex or enamel paint.

Revise as follows:

**R702.7.3 Minimum clear airspaces and vented openings for vented cladding.** For the purposes of this section, vented cladding shall include the following minimum clear airspaces: a minimum 3/16-inch (4.8 mm) airspace. Other openings with the equivalent vent area shall be permitted.

1. Vinyl polypropylene or horizontal aluminum siding applied over a weather resistant barrier as specified in Table R703.3(1);
2. Brick veneer with a clear airspace as specified in Table R703.8.4;
3. Other approved vented claddings.

**Reason:** First, as written the section title R402.7.3 Minimum clear airspaces and vented openings for vented cladding does not match the code language below which is defining vented cladding. It appears that vented cladding is being used as an example of what minimum clear air spaces is but it is very confusing and most are unclear what the section is trying to do. If vented cladding needs to be defined a new section should be create to do so. In my option it does not need to be defined, but the minimum clear airspace certainly does.
As we know vapor retarders are designed to stop or limit the amount of moisture that can diffuse into a building assembly. They however do not stop moisture that moves with air and science has determined that 90 plus percent of the moisture that enters our building assemblies gets there via air leakage vs. vapor diffusion. Therefore, our concern regarding trapping moisture in assemblies and the drying potential of the assemblies we build is on the rise. With that in mind this proposal is striving to attain two things. First a realization that the choice of vapor retarder that is used should be based on the structure and the climate that structure is built in. We should dictate that a vapor retarder is installed, but not proclaim that only one type is best for a specific climate zone. Second, specifically when class three vapor retarders are used it has been shown that the vented space does not need to be more than 3/16 of an inch. The structure of the code does not called out the size of the vented opening which is causing builders to be forced to use class one and two vapor retarders when class three retarders would actually be the best choice for their climate and structure. This occurs because jurisdictions do not have better guidance than some random examples of gaps size behind vented cladding that is currently given in the code. This is especially true in dry climate zones but is an issue everywhere.

In Joe Lstiburek’s article titled “Wufi – Barking up the Wrong Tree” he demonstrates that wood siding that is installed over a 3/16” gap has air movement behind it that is equivalently to approximately 20 air changes per hour. See table 2 cladding ventilation/sheathing ventilation. Lstiburek continues in his article titled, “Hockey Pucks and Hydrostatic Pressure” to demonstrate the “you need to install wood siding and trim over a small gap to control hydrostatic pressure. This gap can be as small as ¼” and the spacer can be a strip of thin foam” such as sill seal which is what is pictured in the photographs that accompany the paper.

Are Vapor Barriers Required or Recommended?

BY JUAN RODRIGUEZ Updated December 30, 2018

https://www.thebalancesmb.com/what-is-a-vapor-barrier-845075

Cost Impact: The code change proposal will not increase or decrease the cost of construction
Cost Statement:
There are no construction cost increases associated with the clarification and flexibility that are achieved through this code change proposal.
2018 International Residential Code

Revise as follows:

R702.7 Vapor retarders. Class I or II vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4. Where a Class II vapor retarder is used in combination with foam plastic insulating sheathing installed as continuous insulation on the exterior side of frame walls, the continuous insulation shall provide the minimum R values indicated in Table R702.7. The Class II vapor retarder shall have a vapor permeance greater than 1 perm when measured by ASTM E96 water method, Procedure B. Use of a Class I interior vapor retarder in frame walls with a Class I vapor retarder on the exterior side shall require an approved design.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.
4. Conditions where Class III vapor retarders are permitted in Section R702.7.1.

Add new text as follows:

<table>
<thead>
<tr>
<th>CLIMATE ZONE</th>
<th>CLASS II VAPOR RETARDERS PERMITTED FOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Continuous insulation with R-value &gt;= 2</td>

</tbody>
</table>

In addition to the vapor retarder, spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement only for the moisture control purposes of this table where the spray foam R-value plus any continuous insulation R-value provided meets or exceeds the specified continuous insulation R-value.

Reason: This proposal is identical to a proposal (FS120-18) approved for the 2021 IBC. It provides needed...
requirements for appropriate use of continuous insulation where a Class II vapor retarder is used and conservatively limits use of Class I vapor retarder. These requirements are based on an extensive review of research and code requirements in the U.S. and Canada and also are consistent with the National Building Code of Canada (ABTG, 2015; ASTM 2017). The effectiveness of these requirements have also been confirmed in recent monitoring of actual homes across northern climates of the U.S. by the Home Innovation Research Lab (Kochkin and Shaw, 2017).

Various associations developed proposals to modify the 2021 Group A vapor retarder section which were subsequently approved by the ICC membership. These proposals act as a package of changes that improve the format and content of this code section. The collaborative group believes this package of code changes will result in regulations that adequately address the moisture management in residential buildings. We have submitted a similar grouping of proposals to make a corresponding change to the IRC. The table below correlates the code proposals between the Group A and B hearings.

**Bibliography:**

**Cost Impact:**

The code change proposal will not increase or decrease the cost of construction. The use of a Class I or II vapor retarder are options and other options are unchanged. Also, the proposal provides appropriate guidance for use of continuous insulation that, in many cases will allow less insulation to be used than required with use of a Class III vapor retarder. It will also allow conformance with prescriptive energy code R-value requirements without exceeding those requirements for moisture control purposes. Thus, in many cases this proposal may reduce cost.
RB221-19
IRC: R702.7, R702.7.4(New)

Proponent: Theresa Weston, representing Air Barrier Association of America (ABAA) (theresa.a.weston@dupont.com)

2018 International Residential Code
Revise as follows:

R702.7 Vapor retarders. Class I or II vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4 to protect the exterior wall assembly against condensation. Vapor retarders shall be installed in accordance with Section R702.7.4.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.

Add new text as follows:

702.7.4 Installation Vapor retarders shall be installed in accordance with the manufacturer’s instructions or an approved design. The vapor retarder shall be installed as an air barrier or in conjunction with an air barrier.

Reason: For vapor retarders to perform as intended, they need to be installed as or in conjunction with an air barrier.

Air leakage control is currently dealt with in the I-codes based on energy efficiency considerations, but it is also critical to protection against moisture condensation. Air leakage can move 100x more moisture than vapor diffusion, and vapor retarders will not work properly without air leakage control. As stated in the Whole Building Design Guide:

“Moisture contributed by air leakage is a significant source and should be a serious concern in the design of the wall system. In fact, the design of the building envelope for minimizing air leakage is more critical than the design of the vapor barrier. To illustrate this point, consider that the amount of moisture contributed to a building by the air that flows through a crack 1/16th inch thick by 1 foot long is just over 5 pints per day in a light breeze. In contrast, the amount of moisture contributed by vapor diffusion through a 10 foot by 50-foot painted block wall over the same period equals just under 1/3 of a pint (about 5 ounces).”

It is important to include air leakage control in Section R702.7 as it will highlight its importance to moisture management and facilitate the inclusion of air leakage control in water management details.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal should neither increase nor decrease the cost of construction, as its intention is to ensure that an existing requirement is installed in an effective manner.
2018 International Residential Code

Delete and substitute as follows:

R702.7 Vapor retarders. Class I or II vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4:

   Exceptions:
   1. Basement walls.
   2. Below-grade portion of any wall.
   3. Construction where moisture or its freezing will not damage the materials.

R702.7 Vapor retarders. Vapor retarder materials shall be classified in accordance with Table R702.7(1). A vapor retarder shall be provided on the interior side of frame walls in accordance with Table R702.7(2) including compliance with Table R702.7(3) where applicable. Alternatively, an approved design using accepted engineering practice for hygrothermal analysis shall be used. The appropriate climate zone shall be selected in accordance with Section N1101.7 (R301.1).

   Exceptions:
   1. Basement walls.
   2. Below-grade portion of any wall.
   3. Construction where accumulation, condensation, or freezing of moisture will not damage the materials.

</table>

For SI: 1 pound per cubic foot = 16 kg/m$^3$.

a. Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement where the spray foam R-value meets or exceeds the specified continuous insulation R-value.

b. Vented cladding shall include vinyl, polypropylene, or horizontal aluminum siding, brick veneer with a clear airspace as specified in Table R703.8.4, and other approved vented claddings.

Delete without substitution:

**R702.7.1 Class III vapor retarders.** Class III vapor retarders shall be permitted where any one of the conditions in Table R702.7.1 is met.

**R702.7.2 Material vapor retarder class.** The vapor retarder class shall be based on the manufacturer’s certified testing or a tested assembly. The following shall be deemed to meet the class specified:
1. Class I: Sheet polyethylene, on perforated aluminum foil.
2. Class II: Kraft-faced fiberglass batts.
3. Class III: Latex or enamel paint.

**R702.7.3 Minimum clear airspaces and vented openings for vented cladding.** For the purposes of this section, vented cladding shall include the following minimum clear airspaces. Other openings with the equivalent vent area shall be permitted.

1. Vinyl polypropylene or horizontal aluminum siding applied over a weather-resistive barrier as specified in Table R703.3(1).
2. Brick veneer with a clear airspace as specified in Table R703.8.4.
3. Other approved vented claddings.

**Reason:** This proposal reformats the vapor retarder provisions to coordinate the IRC with an identical proposal (FS117-18) that was approved for the 2021 IBC vapor retarder provisions. All of the requirements are arranged for easy “look-up” in tables rather than in text such that requirements for a given climate zone or locality can be easily identified. Also, it is important that the IBC and IRC provisions are coordinated to avoid confusion or contradiction.

Various associations developed proposals to modify the 2021 Group A vapor retarder section which were subsequently approved by the ICC membership. These proposals act as a package of changes that improve the format and content of this code section. The collaborative group believes this package of code changes will result in regulations that adequately address the moisture management in residential buildings. We have submitted a similar grouping of proposals to make a corresponding change to the IRC. The table below correlates the code proposals between the Group A and B hearings.

a. The requirements in this table apply only to insulation used to control moisture in order to permit the use of Class II vapor retarders. The insulation materials used to satisfy this option also contribute to but do not supersede the thermal envelope requirements of Chapter 11.

Delete and substitute as follows:

R702.7.1 Class III vapor retarders. Class III vapor retarders shall be permitted where any one of the conditions in Table R702.7.1 is met.

R702.7.1 Spray foam plastic insulation for moisture control with Class II and III vapor retarders. For purposes of compliance with Tables R702.7(3) and R702.7(4), spray foam with a maximum permeance of 1.5 perms at the installed thickness applied to the interior side of wood structural panels, fiberboard, insulating sheathing or gypsum shall be deemed to meet the continuous insulation moisture control requirement in accordance with one of the following conditions:

1. The spray foam R-value is equal to or greater than the specified continuous insulation R-value.
2. The combined R-value of the spray foam and continuous insulation is equal to or greater than the specified continuous insulation R-value.

Delete without substitution:
R702.7.2 Material vapor retarder class. The vapor retarder class shall be based on the manufacturer’s certified testing or a tested assembly. The following shall be deemed to meet the class specified:

1. Class I: Sheet polyethylene, on perforated aluminum foil.
2. Class II: Kraft-faced fiberglass batts.
3. Class III: Latex or enamel paint.

R702.7.3 Minimum clear airspaces and vented openings for vented cladding. For the purposes of this section, vented cladding shall include the following minimum clear airspaces. Other openings with the equivalent vent area shall be permitted:

1. Vinyl polypropylene or horizontal aluminum siding applied over a weather-resistive barrier as specified in Table R703.3(1).
2. Brick veneer with a clear airspace as specified in Table R703.8.4.
3. Other approved vented claddings.

Reason: This proposal represents a compilation (sum effect) of all vapor retarder proposals approved for the 2021 IBC. This proposal makes no further technical changes to the individual proposals and is intended to demonstrate how all the various individual proposals fit together in a manner consistent with what will appear in the 2021 IBC to ensure consistency between the IBC and the IRC. The justification for the various parts of this "omnibus" proposal are found in the reason statements for the various individual vapor retarder (Section R702.7) proposals which also are submitted here in Group B for the IRC as they were in the prior Group A code development hearing for Chapter 14 of the IBC. However, if this reconciliation proposal is approved, those individual proposals will be moved for disapproval.

Various associations and individuals developed proposals to modify the 2021 Group A vapor retarder section which were subsequently approved by the ICC membership. These proposals act as a package of changes that improve the format and content of this code section. The collaborative group believes this package of code changes will result in regulations that adequately address the moisture management in residential buildings. We have submitted a similar grouping of proposals to make a corresponding change to the IRC. The table below correlates the code proposals between the Group A and B hearings.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

The sum effect of the proposal (which represents the compilation of various individual proposals approved for
the 2012 IBC in Group A) is to provide a better and more transparent organization of vapor retarder provisions in a table format for easy selection by climate zone. It also provides expanded and improved options. In some specific cases costs may increase or decrease depending on which options are selected to control water vapor in particular climate zones (e.g., Class III vapor retarder in Climate Zone 8), but there are always options that remain in any climate zone that either have no cost impact or which can reduce cost while maintaining water vapor control.

Proposal # 5438

RB223-19
Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee of the American Chemistry Council

2018 International Residential Code

Revise as follows:

**R702.7.1 Class III vapor retarders.** Class III vapor retarders shall be permitted in Climate Zones 1 through 3 and where any one of the conditions in Table R702.7.1 is met.

</tbody>
</table>

For SI: 1 pound per cubic foot = 16 kg/m³.

a. Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement where the spray foam R-value meets or exceeds the specified continuous insulation R-value.

**Reason:** This proposal coordinates with an identical Group A proposal (FS125-18) approved for the 2021 IBC. It corrects and clarifies appropriate use of a Class III vapor retarder, applying it to all of Climate Zone 4 and permitting its use in Climate Zones 1-3 (not just those climate zones indicated in the table where additional requirements apply).

Various associations developed proposals to modify the 2021 Group A vapor retarder section which were
subsequently approved by the ICC membership. These proposals act as a package of changes that improve the format and content of this code section. The collaborative group believes this package of code changes will result in regulations that adequately address the moisture management in residential buildings. We have submitted a similar grouping of proposals to make a corresponding change to the IRC. The table below correlates the code proposals between the Group A and B hearings.

6. Improves requirements for vapour vents to ensure performance |
Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The use of a Class III vapor retarder is optional. However, where it is used, it can reduce cost of construction and this proposal clarifies and extends the applicability.

Proposal # 4524

RB224-19
**2018 International Residential Code**

Revise as follows:

![Table](attachment:image.png)

For SI: 1 pound per cubic foot = 16 kg/m³.

- Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement where the spray foam $R$-value meets or exceeds the specified continuous insulation $R$-value.

**Reason:** This proposal coordinates with an identical proposal (FS127-18) approved for the 2021 IBC. It corrects an inadvertent extension of Climate Zone 7 requirements into Climate Zone 8 when the table was first introduced to the IBC and IRC. It provides consistent requirements and performance for Climate Zone 8 distinct from Climate Zone 7 that accounts for the colder climate in Climate Zone 8.

Various associations developed proposals to modify the 2021 Group A vapor retarder section which were subsequently approved by the ICC membership. These proposals act as a package of changes that improve...
The collaborative group believes this package of code changes will result in regulations that adequately address the moisture management in residential buildings. We have submitted a similar grouping of proposals to make a corresponding change to the IRC. The table below correlates the code proposals between the Group A and B hearings.

Cost Impact: The code change proposal will increase the cost of construction. The more stringent provisions in Climate Zone 8 are necessary to ensure equivalent vapor/moisture control performance in Climate Zone 8 and will decrease cost in the long run.

Proposal # 4525

RB225-19
R702.7.1 Class III vapor retarders. Class III vapor retarders shall be permitted where any one of the conditions in Table R702.7.1 is met.

Add new text as follows:

**R702.7.1.1 Spray foam plastic insulation for moisture control with Class III vapor retarders.** For the purposes of compliance with Table R702.7.1, spray foam with a maximum permeance of 1.5 perms at the installed thickness applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum shall be deemed to meet the continuous insulation R-value requirement where the spray foam R-value meets or exceeds the specified continuous insulation R-value.

**R702.7.1.2 Hybrid insulation for moisture control with Class III vapor retarders.** For the purposes of compliance with Table R702.7.1, the combined R-values of spray foam plastic insulation and continuous insulation shall be permitted to be counted towards the continuous R-value requirement.

Revise as follows:

<table>

<tr>
<td></td>
<td>Continuous insulation with R-value ≥ 15 over 2 × 6 wall.</td>
</tr>
</tbody>
</table>

For SI: 1 pound per cubic foot = 16 kg/m³.
a. Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement where the spray foam $R$-value meets or exceeds the specified continuous insulation $R$-value.

**Reason:** Table R702.7.1 includes various combinations of continuous insulation used as part of wall assemblies with Class III vapor retarders. Footnote “a” to the table provides an option to use spray foam as an alternative to the continuous insulation requirement. This proposal moves the footnote to the code text and adds an option for hybrid assemblies with a combination of continuous insulation and spray foam. Given that the code permits either option, it is logical that combinations are also acceptable, but that option is not currently included. This proposed requirement is consistent with the provisions for the IBC as approved in proposal FS122-18.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal is an editorial clarification.

Proposal # 5621

RB226-19
2018 International Residential Code

Revise as follows:

**TABLE R702.7.1**

**CLASS III VAPOR RETARDERS**

<table>

</tbody>
</table>

For SI: 1 pound per cubic foot = 16 kg/m³.

a. Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation moisture control requirement where the spray foam R-value meets or exceeds the specified continuous insulation R-value.

b. The requirements in this table apply only to insulation used to control moisture in order to permit the use of Class III vapor retarders. The insulation materials used to satisfy this option contribute to but do not supersede the thermal envelope requirements of Chapter 11.

**Reason:** The proposal clarifies that spray foam used to satisfy the continuous insulation requirements is intended to be used for moisture control. It adds an additional footnote to the table to clarify that the provisions of the IECC are not supplanted by this option. This proposal is identical to FS120-18 that has been approved for inclusion in the 2021 IBC.
**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal is editorial.

Proposal # 5630

RB227-19
RB228-19

IRC®: R702.7.2

Proponent: John Woestman, representing Extruded Polystyrene Foam Association
(jwoestman@kellencompany.com)

2018 International Residential Code

Revise as follows:

R702.7.2 Material vapor retarder class. The vapor retarder class shall be based on the manufacturer’s certified testing or a tested assembly.
The following shall be deemed to meet the class specified:

1. Class I: Sheet polyethylene, on perforated aluminum foil with a perm rating of not more than 0.1.
2. Class II: Kraft-faced fiberglass batts or vapor retarder paint applied in accordance with the manufacturer’s instructions for a perm rating greater than 0.1 and not more than 1.0.
3. Class III: Latex or enamel paint applied in accordance with the manufacturer’s instructions for a perm rating of greater than 1.0 and not more than 10.0.

Reason: Recommending revisions in the IRC to be consistent with 2021 IBC, as modified by proposal FS131-18.

This proposal clarifies that where paints are used as vapor retarders they must be applied in accordance with the manufacturer’s instructions to achieve the required perm rating for the vapor retarder class. Misuse or misapplication of paints that also may not be specifically recommended for use as vapor retarders has been shown to increase the risk of moisture problems in walls with Class III vapor retarders. Cases have been documented where paint applications have a water vapor permeance of more than three times greater than the maximum limit for Class III vapor retarders. As a result, walls intended to rely on Class III vapor retarders can experience an increased risk of moisture accumulation problems. This proposal will provide the ability to avoid this problem.

Also, consistent with the IBC, this proposal includes the appropriate perm ratings in each Class of vapor retarders.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal clarifies the intent of the code and does not impact cost.

Proposal # 5247
**2018 International Residential Code**

Revise as follows:

**R702.7.2 Material vapor retarder class.** The vapor retarder class shall be based on the manufacturer's certified testing or a tested assembly.

The following shall be deemed to meet the class specified:

1. Class I: Sheet polyethylene, on perforated aluminum foil.
2. Class II: Kraft-faced fiberglass batts.
3. Class III: Latex or enamel paint.

The vapor retarder class of latex or enamel paint shall be determined based on the perm rating provided by the paint manufacturer.

**Reason:** The purpose of this code change is to remove the automatic assumption that latex paint and enamel paint meets the requirements of a Class III vapor retarder. Depending on the paint thickness, number of coats, and type of primer used, the actual water vapor permeance can far exceed the 1 perm to 10 perm range which defines a Class III vapor retarder. Field studies using test huts or test houses have shown that a coat of primer and 2 coats of standard latex paint can have a perm rating of as much as 50. In one study using test huts in Climate Zone 4A, wall assemblies consisting of un-faced batt insulation and an interior painted wall developed mold within 6 months. In another recent study of 22 houses in a range of climate zones, some wall assemblies meeting the requirements of Table R702.7.1 but relying on gypsum board and paint as a Class III interior vapor retarder showed high cyclic winter moisture contents.

Some paint manufacturers also produce a paint explicitly formulated to act as a Class II vapor retarder, if not Class I. When installed per the manufacturer's instruction to the specified thickness and number of coats, plus any primer coat, these paints can achieve a tested water vapor permeance per ASTM E96 of less than 1.0 perm, qualifying as a Class II vapor retarder or better. The current code language has resulted in difficulty convincing some building officials to accept low-perm paints as a Class II or better vapor retarder. Removing the automatic classification and allowing the manufacturer's specified perm rating and application instructions to be used is intended to help clarify when paints with high vapor-retarding properties (i.e. low perm ratings) can be used.

This change will also align the material specifications in Section R702.7.2 with IBC Section 1404.3 as modified for the 2021 IBC by approved proposal FS117-18.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.
perm ratings for paints sold as vapor retarding paints.

Proposal # 4738

RB229-19
2018 International Residential Code

Revise as follows:

R702.7.3 Minimum clear airspaces and vented openings for vented cladding. For the purposes of this section, vented cladding shall include the following minimum clear airspaces. Other openings with the equivalent vent area shall be permitted.

1. Vinyl polypropylene or horizontal aluminum siding applied over a weather-resistant barrier as specified in Table R703.3(1).
2. Brick veneer, anchored stone or masonry veneer with a clear airspace as specified in Table R703.8.4(1).
3. Other approved vented claddings.

Reason: Revising Item 2 to use a term defined in the IRC and to be consistent with the veneer included in Section R703.8 (anchored stone and masonry veneer) and which is required to be installed with an airspace, per Table R703.8.4(1), of between 1" and 4 ½". Retaining “brick veneer” even though redundant with “masonry veneer”, for clarity and consistency. It follows that if brick veneer with a (required) airspace per Table R703.8.4(1) is considered vented cladding, then anchored stone or (other) masonry veneer required to be installed with the same airspace requirements should also be considered vented cladding.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal is identifying all the types of (anchored) masonry veneer required by the IRC to be installed with a clear airspace, which results in a vented cladding. This should not increase or decrease the cost of construction.
RB231-19

IRC®: R703.2

Proponent: Paul Coats, representing American Wood Council (pcoats@awc.org)

2018 International Residential Code

Revise as follows:

R703.2 Water-resistive barrier. One layer of No. 15 asphalt felt, free from holes and breaks, complying with ASTM D226 for Type 1 felt or other approved water-resistive barrier shall be applied over studs or sheathing of all exterior walls. No.15 asphalt felt shall be applied horizontally, with the upper layer lapped over the lower layer not less than 2 inches (51 mm). Where joints occur, felt shall be lapped not less than 6 inches (152 mm). Other approved materials shall be installed in accordance with the water-resistive barrier manufacturer’s installation instructions. The No. 15 asphalt felt or other approved water-resistive barrier material shall be continuous to the top of walls and terminated at penetrations and building appendages in a manner to meet the requirements of the exterior wall envelope as described in Section R703.1.

Exception: A water-resistive barrier shall not be required in detached accessory structures that are not heated or cooled.

Reason: For many years the code exempted accessory structures from the requirement for a water resistive barrier. The exception was removed from the code in the previous cycle, but the exception that was removed applied to all accessory structures, regardless of their purpose and regardless of whether they were heated or cooled. This proposal will not exempt conditioned (heated or cooled) accessory structures, which are more subject to movement of moisture through the exterior walls than unconditioned ones. Unconditioned detached accessory structures such as sheds and storage structures have a proven record of performance when complying with the normal siding installation requirements without a water resistive barrier as defined in the code. Unconditioned structures are typically used to store yard tools, lawn mowers, tractors, hay, boats, road salts, including certain amounts of fume-producing fuels and lubricants. They often do not have interior wall coverings or insulation, but instead have exposed framing with siding and no wall sheathing. Installing a water resistive barrier directly to framing without wall sheathing is difficult, and the barrier would be easily punctured by yard tools or other objects leaning against the walls. In addition, they could hinder the natural ventilation needed to disperse fumes and heat. Structures that are heated or cooled are more likely to have insulation and therefore the water resistive barrier makes sense, but an exception is needed for unconditioned structures which have been adequately served by the siding provisions in the code.

Cost Impact: The code change proposal will decrease the cost of construction
This may decrease the cost of construction for certain unconditioned accessory structures.

Proposal # 4273
2018 International Residential Code

Delete and substitute as follows:

R703.2 Water-resistive barrier. One layer of No. 15 asphalt felt, free from holes and breaks, complying with ASTM D226 for Type 1 felt or other approved water-resistive barrier shall be applied over studs or sheathing of all exterior walls. No. 15 asphalt felt shall be applied horizontally, with the upper layer lapped over the lower layer not less than 2 inches (51 mm). Where joints occur, felt shall be lapped not less than 6 inches (152 mm). Other approved materials shall be installed in accordance with the water-resistive barrier manufacturer's installation instructions. The No. 15 asphalt felt or other approved water-resistive barrier material shall be continuous to the top of walls and terminated at penetrations and building appendages in a manner to meet the requirements of the exterior wall envelope as described in Section R703.1.

R703.2 Water-resistive barrier. Not fewer than one layer of water-resistive barrier shall be applied over studs or sheathing with flashing as indicated in Section R703.4, in such a manner as to provide a continuous water-resistive barrier behind the exterior wall veneer. Water-resistive barrier materials shall comply with one of the following:

1. No. 15 felt complying with ASTM D226, Type 1
2. ASTM E2556, Type 1 or 2
3. ASTM E331 in accordance with Section R703.1.1, or
4. Other approved materials in accordance with the manufacturer's installation instructions.

Add new text as follows:

E2556/E2556M-10: Standard Specification for Vapor Permeable Flexible Sheet Water-resistive Barriers Intended for Mechanical Attachment

Reason: Objective: Provide more flexible definition of WRB to account for new innovations that are not sheet applied materials as defined by ASTM D226 or ASTM E2556. Amend IRC R703.2 in Cycle B with same language submitted in cycle A for IBC

The existing code language gives insufficient guidance for other approved materials. The added language addresses this issue and provides a specific performance requirement for water resistance and provides consistency with other sections of the code that relate specifically to water-resistive barriers.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change gives better guidance for water resistance.

Staff Analysis: The referenced standard, ASTM E2556/E2556M-10, is currently referenced in other 2018 I-codes.
R703.2 Water-resistive barrier. One layer of No. 15 asphalt felt, free from holes and breaks, complying with ASTM D226 for Type 1 felt or other approved water-resistive barrier shall be applied over studs or sheathing of all exterior walls. No. 15 asphalt felt shall be applied horizontally, with the upper layer lapped over the lower layer not less than 2 inches (51 mm). Where joints occur, felt shall be lapped not less than 6 inches (152 mm). Other approved materials shall be installed in accordance with the water-resistive barrier manufacturer’s installation instructions. The No. 15 asphalt felt or other approved water-resistive barrier material shall be continuous to the top of walls and terminated at penetrations and building appendages in a manner to meet the requirements of the exterior wall envelope as described in Section R703.1.

R703.2 Water-resistive barrier. Not fewer than one layer of water-resistive barrier shall be applied over studs or sheathing of all exterior walls with flashing as described in Section R703.4, in such a manner as to provide a continuous water-resistive barrier behind the exterior wall veneer. The water-resistive barrier material shall be continuous to the top of walls and terminated at penetrations and building appendages in a manner to meet the requirements of the exterior wall envelope as described in Section R703.1. Water-resistive barrier materials shall comply with one of the following:

1. No. 15 felt complying with ASTM D226, Type 1
2. ASTM E2556, Type I or II
3. ASTM E331 in accordance with Section R703.1.1
4. Other approved materials installed in accordance with the manufacturer’s installation instructions.
5. No.15 asphalt felt and water-resistive barriers complying with ASTM E2556 shall be applied horizontally, with the upper layer lapped over the lower layer not less than 2 inches (51 mm), and where joints occur, shall be lapped not less than 6 inches (152 mm).

Add new text as follows:

**E2556/E2556M—10:** Standard Specification for Vapor Permeable Flexible Sheet Water-resistive Barriers Intended for Mechanical Attachment

**Reason:** This proposal recognizes the broad range of water-resistive barriers available to the market in addition to the one traditional material currently recognized. This proposal is consistent with a change made to Chapter 14 of the IBC in Group A of this code change cycle, but the change merges that change with more prescriptive language in the IRC

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change does not add requirements to the code. It explicitly lists the various types of water-resistive barriers which are currently approved through evaluation services reports.
Staff Analysis: The referenced standard, E2556/E2556M—10, is currently referenced in other 2018 I-codes.
2018 International Residential Code

Revise as follows:

R703.3.1 Soffit installation. Soffits shall comply with Section R703.3.1.1, Section R703.3.1.2 or the manufacturer's installation instructions. 

Delete without substitution:

R703.3.1.1 Wood structural panel soffit. The minimum nominal thickness for wood structural panel soffits shall be 3/16 inch (9.5 mm) and shall be fastened to framing or nailing strips with 2-inch by 0.099-inch (51 mm × 2.5 mm) nails. Fasteners shall be in spaced not less than 6 inches (152 mm) on center at panel edges and 12 inches (305 mm) on center at intermediate supports.

R703.3.1.2 Vinyl soffit panels. Soffit panels shall be fastened at fascia and wall ends and to intermediate nailing strips as necessary to ensure that there is no unsupported span greater than 16 inches (406 mm), or as specified by the manufacturer's instructions.

Add new text as follows:

SECTION R704
SOFITS

R704.1 General wind limitations. Where the design wind pressure is 30 psf or less, soffits shall comply with Section R704.2. Where the design wind pressure exceeds 30 psf, soffits shall comply with Section R704.3. The design wind pressure on soffits shall be determined using the component and cladding loads specified in Table R301.2(2) for walls using an effective wind area of 10 square feet and adjusted for height and exposure in accordance with Table R301.2(3).

R704.2 Soffit installation where the design wind pressure is 30 psf or less. Where the design wind pressure is 30 psf or less, soffit installation shall comply with Section R704.2.1, Section R704.2.2, Section R704.2.3, or Section R704.2.4.

R704.2.1 Vinyl soffit panels. Vinyl soffit panels shall be installed using fasteners specified by the manufacturer and shall be fastened at both ends to a supporting component such as a nailing strip, fascia or subfascia component. Where the unsupported span of soffit panels is greater than 16 inches, intermediate nailing strips shall be provided in accordance with Figure R704.2.1. Vinyl soffit panels shall be installed in accordance with the manufacturer's installation instructions. Fascia covers shall be installed in accordance with the manufacturer's installation instructions.
R704.2.2 Fiber-cement soffit panels. Fiber-cement soffit panels shall be a minimum of 1/4 inch in thickness and shall comply with the requirements of ASTM C1186, Type A, minimum Grade II or ISO 8336, Category A, minimum Class 2. Panel joints shall occur over framing or over wood structural panel sheathing. Soffit panels shall be installed with spans and fasteners in accordance with the manufacturer’s installation instructions.

R704.2.3 Hardboard soffit panels. Hardboard soffit panels shall be a minimum of 7/16 inch in thickness and shall be fastened to framing or nailing strips with 2 ½” x 0.113” siding nails spaced not more than 6 inches on center at panel edges and 12 inches on center at intermediate supports.

R704.2.4 Wood structural panel soffit. The minimum nominal thickness for wood structural panel soffits shall be 3/8 inch (9.5 mm) and shall be fastened to framing or nailing strips with 2-inch by 0.099-inch (51 mm x 2.5 mm) nails. Fasteners shall be spaced not less than 6 inches (152 mm) on center at panel edges and 12 inches (305 mm) on center at intermediate supports.

R704.3 Soffit installation where the design wind pressure exceeds 30 psf. Where the design wind pressure is greater than 30 psf, soffit installation shall comply with Section R704.3.1, Section R704.3.2, Section R704.3.3, or Section R704.3.4.

R704.3.1 Vinyl soffit panels. Vinyl soffit panels and their attachments shall be capable of resisting wind loads specified in Table R301.2(2) for walls using an effective wind area of 10 square feet and adjusted for height and exposure in accordance with Table R301.2(3). Vinyl soffit panels shall be installed using fasteners specified by the manufacturer and shall be fastened at both ends to a supporting component such as a nailing strip, fascia or subfascia component. Where the unsupported span of soffit panels is greater than 12 inches, intermediate nailing strips shall be provided in accordance with Figure R704.2.1. Vinyl soffit panels shall be installed in
accordance with the manufacturer’s installation instructions. Fascia covers shall be installed in accordance with the manufacturer’s installation instructions.

**R704.3.2 Fiber-cement soffit panels.** Fiber-cement soffit panels shall comply with Section R704.2.2 and shall be capable of resisting wind loads specified in Table R301.2(2) for walls using an effective wind area of 10 square feet and adjusted for height and exposure in accordance with Table R301.2(3).

**R704.3.3 Hardboard soffit panels.** Hardboard soffit panels shall comply with the manufacturer’s installation instructions and shall be capable of resisting wind loads specified in Table R301.2(2) for walls using an effective wind area of 10 square feet and adjusted for height and exposure in accordance with Table R301.2(3).

**R704.3.4 Wood structural panel soffit.** Wood structural panel soffits shall be capable of resisting wind loads specified in Table R301.2(2) for walls using an effective wind area of 10 square feet and adjusted for height and exposure in accordance with Table R301.2(3). Alternatively, wood structural panel soffits shall be installed in accordance with Table R704.3.4.

</table>
a. Fasteners shall comply with Sections R703.3.2 and R703.3.3.
b. Maximum spacing of soffit framing members shall not exceed 24 inches.
c. Wood structural panels shall be of an exterior exposure grade.
d. Wood structural panels shall be installed with strength axis perpendicular to supports with a minimum of two continuous spans.
e. Wood structural panels shall be attached to soffit framing members with specific gravity of at least 0.42. Framing members shall be minimum 2x3 nominal with the larger dimension in the cross section aligning with the length of fasteners to provide sufficient embedment depths.
f. Spacing at intermediate supports shall not be greater than 12 inches on center.

**Reason:** The purpose of this code change proposal is to improve the wind performance of soffits by clarifying International Residential Code (IRC) installation requirements for the most common types of manufactured soffits and by providing a prescriptive alternative for wood structural panel soffits that complies with design wind pressures specified in the IRC and ASCE 7. The proposal's sponsor and co-sponsor developed content in collaboration with representatives from American Wood Council, National Association of Home Builders, Vinyl Siding Institute, and other soffit manufacturer groups. The code change refines and further clarifies provisions that were adopted into the 2018 IRC and adds new provisions to address soffit installation in high wind regions. The proposal also moves the clarified soffit provisions to the new Section 704 to better distinguish from exterior wall covering provisions that make up nearly all of Section 703. In addition to separating the clarified soffit provisions to prevent them from being overlooked, new soffit provisions can easily be added as needed with this improved organization and simplified format.

As part of the response to Hurricane Harvey in Texas and Hurricane Irma in Florida, the Federal Emergency Management Agency (FEMA) deployed Mitigation Assessment Teams (MATs) composed of national and regional building science experts to assess the damage in both States. The primary purpose of a MAT is to improve the natural hazard resistance of buildings by evaluating the key causes of building damage, failure, and success, and developing strategic recommendations for improving short-term recovery and long-term disaster resilience from future natural hazard events. The following MAT-related information is included in the FEMA MAT Reports: Hurricane Irma in Florida and Hurricane Harvey in Texas. Links to download the free report will be shared with IRC Committee members for reference upon publication.

The FL MAT observed building envelope damage on both older and newer residential construction, and soffits were among the most frequently observed damaged envelope components. Based on estimated wind speeds at the sites visited, failure occurred to soffit components at wind speeds well below design wind speeds for these areas. The FL MAT observed both vinyl and metal soffit loss, but vinyl soffit panels were the most common product observed, particularly in the Florida Keys where vinyl soffit damage was widespread.

In many cases, inadequate support and attachment at the ends of the soffit panel led to failure of the soffit. The Sugarloaf Key house shown below (FL MAT Report Figure 4-19) lost its vinyl soffit in several areas. The red oval shows where the soffit panel was stripped from the assembly’s J-channel, which remains attached along the exterior wall (yellow arrows). The soffit appears to have been fastened to only a single nailing strip across the midpoint of the framing above. Section 704.2.1 (including Figure 704.2.1) of the proposal has been included to clarify that vinyl soffit panels are required to be fastened at each end and the unsupported span cannot exceed specified limits (16 or 12 inches) unless permitted by the manufacturer’s product approval.
In some cases, vinyl soffit failure appeared to have been associated with fascia cover loss as shown in the image below from Little Torch Key (FL MAT Report Figure 4-18). Loss of the fascia cover likely increases wind pressures on vinyl soffit where the edges of the soffit are exposed.
The TX MAT observed similar wind damage to residential soffits as indicated below. The dwelling in Cape Valero shown on the left (TX MAT Figure 4-44) lost re-covered vinyl soffit panels (green arrow) to high winds, exposing the vent opening (red arrows) to wind driven rain. The photo on the right (TX MAT Figure 4-45) shows a soffit opening that was previously covered by a ventilating fiber-cement board. Red arrows indicate where the attic is exposed to wind driven rain. As with examples shown from Florida, estimated wind speeds for the sites were below design wind speeds.
FL and TX MAT observations described above along with other examples detailed in the MAT Reports, led to
the following conclusions and recommendations:

Conclusion FL-10: The MAT observed evidence of inadequate resistance to wind pressures and improper
installation of soffits on residential buildings. Widespread loss of soffits was observed in residential construction,
and wind-driven rain infiltrated some areas where soffits were displaced or lost.
Recommendation FL-10a: Designers, contractors, and inspectors should place more emphasis on proper soffit
installation to limit wind-driven rain. Proper soffit installation should be emphasized by designers, contractors,
and inspectors in order to limit wind-driven rain from entering building envelopes and damaging building
Conclusion TX-18: Many soffits lacked adequate wind resistance, typically because the wrong material was used for the region or it was improperly installed. The MAT observed widespread loss of soffits in residential and non-residential construction, generally due to improper materials, lack of fasteners, and/or inadequate framing, and wind-driven rain infiltrated some areas where soffits were displaced or lost. The loss of soffit vents can allow hurricane winds to drive large amounts of water through the openings and soak insulation, which can lead to mold growth and, in some cases, the collapse of ceilings.

Recommendation TX-18: Designers, contractors, and inspectors should place more emphasis on proper soffit installation in high-wind regions. Wind-driven rain should be limited from entering building envelopes and damaging building interiors through proper soffit installation.

In summary, widespread residential soffit damage observed in the wake of the 2017 Hurricane Season indicates the need for clarified installation provisions in the IRC. The proposed provisions apply to design wind pressures realized across the US, but are clearly differentiated where 30 pounds per square foot (psf) or less or where greater than 30 psf, so that installation requirements are tailored for the site-specific pressures. Regardless the soffit design wind pressure, the new provisions will provide greater clarity for the builder to implement code-compliant soffit installation and for the building official to verify code-compliant soffit installation.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase the cost of construction for buildings where design wind pressures are 30 psf or less because it only clarifies the existing requirement for soffit installation. The code change proposal may decrease costs for buildings where the design wind pressure exceeds 30 psf because it provides some prescriptive solutions as an alternative to design.
**RB235-19**

**IRC®: R703.3.1.1**

**Proponent:** Borjen Yeh, APA - The Engineered Wood Association, representing APA - The Engineered Wood Association (borjen.yeh@apawood.org); Ralph Leyva, representing APA - The Engineered Wood Association (ralph.leyva@apawood.org)

**2018 International Residential Code**

Revise as follows:

**R703.3.1.1 Wood structural panel soffit.** The minimum nominal thickness for wood structural panel soffits shall be \(\frac{3}{8}\) inch (9.5 mm) and shall be fastened to framing or nailing strips with 2-inch by 0.099-inch (51 mm × 2.5 mm) nails. Fasteners shall be in-spaced not less greater than 6 inches (152 mm) on center at panel edges and 12 inches (305 mm) on center at intermediate supports.

**Reason:** This proposal is intended to correct an oversight on the fastener spacing for wood structural panel soffit from the last code cycle. The fastener spacing should not be greater than 6 inches on center at panel edges. Otherwise, the fastener spacing could be indefinitely larger than 6 inches on center.

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal is a correction to an oversight from the last code cycle.

Proposal # 4623
RB236-19
IRC®: R703.4

Proponent: Mike Fischer, Kellen Company, representing The Polyisocyanurate Insulation Manufacturers Association (mfischer@kellencompany.com); Marcin Pazera, representing The Polyisocyanurate Insulation Manufacturers Association (mpazera@pima.org)

2018 International Residential Code

Revise as follows:

R703.4 Flashing. Approved corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. Fluid-applied membranes used as flashing in exterior walls shall comply with AAMA 714. The flashing shall extend to the surface of the exterior wall finish or to a water-resistive barrier that complies with Section R703.2 and is part of a means of drainage complying with Section R703.1.1. Approved corrosion-resistant flashings shall be installed at the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier complying with Section 703.2 for subsequent drainage. Mechanically attached flexible flashings shall comply with AAMA 712. Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:
   1.1. The fenestration manufacturer’s installation and flashing instructions, or for applications not addressed in the fenestration manufacturer’s instructions, in accordance with the flashing manufacturer’s instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. Openings using pan flashing shall incorporate flashing or protection at the head and sides.
   1.2. In accordance with the flashing design or method of a registered design professional.
   1.3. In accordance with other approved methods.

2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

Reason: Item 1 in locations required to be flashed indicates that it is acceptable to direct water to the exterior of the WRB for subsequent drainage to the exterior. That option conflicts with the charging language in R703.4 that does not mention the WRB. This proposal is similar to FS133-18 that was approved as submitted by the ICC FS Committee during the Group A Code Development Cycle in 2018; FS133-18 was Approved as Submitted. This proposal creates consistency between the two codes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposal is a clarification of common practice.
R703.4 Flashing. Approved corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. Fluid-applied membranes used as flashing in exterior walls shall comply with AAMA 714. The flashing shall extend to the surface of the exterior wall finish. Approved corrosion-resistant flashings shall be installed at the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall be installed in accordance with R703.4.1, extend to the surface of the exterior wall finish or to the water-resistive barrier complying with Section 703.2 for subsequent drainage. Mechanically attached flexible flashings shall comply with AAMA 712. Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:

   1.1. The fenestration manufacturer’s installation and flashing instructions, or for applications not addressed in the fenestration manufacturer’s instructions, in accordance with the flashing manufacturer’s instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. Openings using pan flashing shall incorporate flashing or protection at the head and sides.

   1.2. In accordance with the flashing design or method of a registered design professional.

   1.3. In accordance with other approved methods.

2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.

3. Under and at the ends of masonry, wood or metal copings and sills.

4. Continuously above all projecting wood trim.

5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.

6. At wall and roof intersections.

7. At built-in gutters.

Add new text as follows:

R703.4.1 Flashing installation at exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier complying with Section 703.2 for subsequent drainage. Mechanically attached flexible flashings shall comply with AAMA 712. Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:

1. The fenestration manufacturer’s installation and flashing instructions, or for applications not addressed in the fenestration manufacturer’s instructions, in accordance with the flashing manufacturer’s instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior
window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water resistive barrier for subsequent drainage. Openings using pan flashing shall incorporate flashing or protection at the head and sides.

2. In accordance with the flashing design or method of a registered design professional.
3. In accordance with other approved methods.

**Reason:** This proposal rearranges the code text for clarity. Currently the list of places in which flashing is required is "broken up" by details on flashing installation at window and door openings. This proposal moves the installation to a later subsection. Therefore, it makes the list of required flashing locations. No technical changes are made to the installation details.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal is a text rearrangement to improve clarity. It does not change any technical requirements.
Proponent: Donald Sivigny, representing State of MN and Association of Minnesota Building Officials
(don.sivigny@state.mn.us)

2018 International Residential Code

Revise as follows:

R703.4 Flashing. Approved corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. Fluid-applied membranes used as flashing in exterior walls shall comply with AAMA 714. The flashing shall extend to the surface of the exterior wall finish. Approved corrosion-resistant flashings shall be installed at the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier complying with Section 703.2 for subsequent drainage. An insulation stop shall be installed around all window and door openings, 1 to 2 inches inward from the face of the exterior sheathing, to allow for drainage of incidental water at the window or door flashing system. Mechanically attached flexible flashings shall comply with AAMA 712. Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:
   1.1. The fenestration manufacturer’s installation and flashing instructions, or for applications not addressed in the fenestration manufacturer’s instructions, in accordance with the flashing manufacturer’s instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. Openings using pan flashing shall incorporate flashing or protection at the head and sides.
   1.2. In accordance with the flashing design or method of a registered design professional.
   1.3. In accordance with other approved methods.
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

Reason: This change will increase the durability of the wall assembly when integrating a fenestration product into the assembly. This code change will enhance the opportunity for water drainage in accordance with the remainder of Section R703.4 to specifically address water drainage at the pan flashing. This proposal provides the opportunity to install fenestration product in compliance with both the Energy Code and the installation instructions of the fenestration manufacturer, by enhancing the drainage of pan flashed fenestration products. The Energy code requires the fenestration products and the framed openings to be insulated and sealed. The installers of these fenestration units almost exclusively use expanding spray foam as a sealant to meet the Energy Codes. When this expanding foam or other sealant flows outward to, or extends to the exterior nailing flange, it actually blocks the free drainage of water to the exterior, allowing water to collect and wick inward.
through capillary action toward the interior of the exterior wall assembly where it will cause degradation of the wall assembly. Maintaining an unobstructed and drainable air space around the perimeter of the fenestration product, and especially the pan flashing, will allow for convective air flow that promotes drying and will elevate water infiltration to the wall assembly. This can be accomplished by installing a barrier or stop to prevent the expanding foam or other sealants from reaching the interior side of the nailing flange where it will create degradation issues within the wall assembly. Unobstructed drainage is essential to the draining of water where the fenestration products interface with the wall assemblies. The existing code language does not have any specific, or enforceable language to require an unobstructed drainage plane at all fenestration products. This code change proposal does not interfere with or override the specific installation instruction of fenestration products into walls assemblies by the manufacturer or the code, but instead, it simply enhances the ability of the wall assembly to drain water and maintain a dry and durable assembly for years to come.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The code change proposal initially may increase or decrease the cost of construction slightly in material, depending on the manufacturer’s installation instructions, however any increase in these cost will more than recovered in the longevity of the assembly and addressing those problems of degradation of wall assemblies at these openings when it is not allowed to drain fully and stay dry. Remember the cost of a Call back to a home is around $350 or above on average.
RB239-19
IRC®: R703.5

Proponent: Matthew Hunter, representing American Wood Council (mhunter@awc.org)

2018 International Residential Code

Revise as follows:

R703.5 Wood, hardboard and wood structural panel siding. Wood, hardboard, and wood structural panel siding shall be installed in accordance with this section and Table R703.3(1). Hardboard siding shall comply with CPA/ANSI A135.6. Hardboard siding used as architectural trim shall comply with CPA/ANSI A135.7.

Reason: The Composite Panel Association (CPA) and its trim producing members, view architectural trim as a non-structural decorative accent that should not be required to be certified to voluntary ANSI A135.7-2012 Engineered Wood Trim Standard in the IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The code change proposal will not increase the cost of construction.

Proposal # 4282
# 2018 International Residential Code

**Revise as follows:**

## TABLE R703.6.3(1)
### SINGLE-COURSE SIDEWALL FASTENERS

<table>

<td>0.0915”</td>
</tr>
<tr>
<td>24” taper-split</td>
<td>5d box $1^{3/4} \times 0.080$</td>
<td>0.19”</td>
<td>0.080”</td>
</tr>
<tr>
<td>18” and 24” tapersawn</td>
<td>6d box $2” \times 0.099$</td>
<td>0.19”</td>
<td>0.0915”</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

**Reason:** The box nail dimensions listed in Tables do not match those listed in ASTM F1667. The nominal head diameter of a 3d box, 4d box and 5d box nail is 0.219 inches with a minimum head diameter of 0.197 inches. The nominal head diameter of a 6d and 7d box nail is 0.266 inches with a minimum head diameter of 0.239 inches. The nominal head diameter of an 8d box nail is 0.297 inches with a minimum head diameter of 0.267 inches. The nominal shank diameter (not shank thickness) of a 3d box nail is 0.076 inches with a minimum of 0.072 inches.
The nominal shank diameter (not shank thickness) of a 4d and 5d box nail is 0.080 inches with a minimum of 0.076 inches.

The nominal shank diameter (not shank thickness) of a 6d and 7d box nail is 0.099 inches with a minimum of 0.095 inches.

The nominal shank diameter (not shank thickness) of an 8d box nail is 0.113 inches with a minimum of 0.109 inches.

Listing the nail type (3d box, 4d box, etc.) and then the nominal length and nominal shank diameter provides a correct description of the fastener.

The Cedar Shake & Shingle Bureau has listed in their installation manuals the use of box nails for installation these products.

In Table R703.6.3(2) the size of the R&R and sanded shingles should read 16", 18" and 24" not 16", 8" and 24".

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

These proposed changes do not change the existing requirements but instead clarify the description of the fasteners.

Proposal # 3843
Proponent: Cesar Lujan, representing National Association of Home Builders (clujan@nahb.org); Gary Ehrlich, National Association of Home Builders, representing National Association of Home Builders (gehrlich@nahb.org)

2018 International Residential Code

R703.7 Exterior plaster (stucco). Installation of exterior plaster shall be in compliance with ASTM C926, ASTM C1063 and the provisions of this code.

Revise as follows:

R703.7.1 Lath. Lath and lath attachments shall be of corrosion-resistant materials in accordance with ASTM C1063. expanded meta, welded wire, or woven wire lath shall be attached to wood framing members with 1 1/2-inch-long (38 mm), 11-gage nails having a 7/16-inch (11.1 mm) head, or 7/8-inch-long (22.2 mm), 16-gage staples, spaced not more than 6 7 inches (152 178 mm) on center vertically and not more than 24 inches on center horizontally, or as otherwise approved. Additional fastening between wood framing members shall not be prohibited. Lath attachments to cold-formed steel framing or to masonry, stone, or concrete substrates shall be in accordance with ASTM C 1063. Where lath is installed directly over foam sheathing, lath connections shall also be in accordance with Sections R703.15, R703.16, or R703.17. Where lath is attached to furring installed over foam sheathing, the furring connections shall be in accordance with Sections R703.15, R703.16, or R703.17.

Exception: Lath is not required over masonry, cast-in-place concrete, precast concrete or stone substrates prepared in accordance with ASTM C1063.

R703.7.3 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-resistive, vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, is directed between the layers.

Exception: Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage space.

Add new text as follows:

703.7.3.1 Furring Where provided, furring between lath and vertical supports or solid sheathing shall consist of wood furring strips not less than 1 inch by 2 inches (25 mm by 51 mm), minimum ¾ inch (19 mm) metal channels, or self-furring lath, and shall be installed in accordance with ASTM C1063. Furring shall be spaced a maximum of 24 inches (600 mm) on center horizontally and, where installed over wood or cold-formed steel framing, shall be fastened into framing members.

Reason: The purpose of this code change is to correlate the requirements for exterior lath and plaster (stucco) with the requirements of ASTM C 926 and C 1063 and recommended practice. The code requirements in the IRC are not in alignment with the reference standards and lack key details needed to insure a good installation and minimize the risk of moisture intrusion.

In particular, the IRC lath attachment requirements state a 6” nail or staple spacing but do not specify direction.
or what nailing substrates are permitted. ASTM C 1063 specifies a 7" vertical spacing along and 16" to 24"
horizontal spacing into wood studs. Without this clear direction in the code, some stucco is being installed with
fasteners in a 6" grid pattern (both horizontal and vertical), leading to fasteners penetrating sheathing and
providing a path for moisture intrusion behind the WRB and exterior sheathing and causing decay and water
damage. The code user is referred to C 1063 for lath attachment requirements for other substrates, and is
allowed to omit the lath when permitted by C 1063 for concrete substrates which have been properly prepared
such that the plaster will bond directly to the concrete.

Also, the IRC does not currently provide any details for furring. Minimum sizes consistent with other wood
furring requirements in the IRC and the minimum channel size from C 1063 are supplied along with the
maximum horizontal spacing. Again, the proposed language underscores that furring attachment to metal or
wood framing must be into studs. Where furring is required between lath and vertical supports or solid surfaces
varies depending on the type of lath or plaster base used and the type of vertical support or surface. Designers
and stucco installers should defer to C 1063 and stucco manufacturer instructions for guidance on where furring
is required.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
The code change aligns the prescriptive language for exterior lath and plaster in the IRC with the ASTM
standards referenced in the section. Since compliance with these standards is already required, this change
simply provides clarification for builders, stucco installers and building officials and thus does not increase the
cost of construction.
2018 International Residential Code

Revise as follows:

R703.7.3 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall comply with Section R703.7.3.1 or Section R703.7.3.2. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, is directed between the layers.

Exception: Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage space.

Add new text as follows:

R703.7.3.1 Dry Climates. In dry (B) climate zones indicated in Figure N1101.7, water-resistive barriers shall comply with one of the following:

1. The water-resistive barrier shall be two layers of 10-minute Grade D paper or have a water resistance equal to or greater than two layers of a water-resistive barrier complying with ASTM E2556, Type I. The individual layers shall be installed independently such that each layer provides a separate continuous plane. Flashing installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, shall be directed between the layers.

2. The water-resistive barrier shall be 60-minute Grade D paper or have a water resistance equal to or greater than one layer of a water-resistive barrier complying with ASTM E2556, Type II. The water-resistant barrier shall be separated from the stucco by a layer of foam plastic insulating sheathing or other non-water-absorbing layer.

R703.7.3.2 Moist or marine climates. In the moist (A) or marine (C) climate zones indicated in Figure N1101.7, water-resistive barriers shall comply with one of the following:

1. In addition to complying with Section R703.7.3.1, a space not less than 3/16 inch (5 mm) in depth shall be added to the exterior side of the water-resistant barrier.

2. In addition to complying with Section R703.7.3.1 Item 2, a space having a drainage efficiency of not less than 90%, as measured in accordance with ASTM E2273 or Annex A2 of ASTM E2925, shall be added to the exterior side of the water-resistive barrier.

ASTM E2925-17: Standard Specification for Manufactured Polymeric Drainage and Ventilation Materials Used to Provide a Rainscreen Function
**Reason:** The proposal does two things. First, it reorganizes the provisions by deleting an exception (which is really a construction option) and replacing it with subsections that indicate different methods of complying with stucco water-resistive barrier requirements. Second, the proposal properly applies requirements in relation to climate -- something that has been missing in the code and is needed to avoid higher risk of moisture problems in climates that are moist/rainy. The proposal will help resolve problems with stucco performance (e.g., moisture problems over wood-based sheathings) and avoid impacting cost or performance where performance has a long-standing record of good performance (e.g., dry climates such as the southwestern region of the U.S.).

**Cost Impact:** The code change proposal will increase the cost of construction. The proposal will not increase cost for substrates other than wood-based sheathing. Also, it will not impact cost or change requirements in dry climates where stucco has a long record of successful performance. This also will not impact cost in moist or marine climates where similar actions are already being taken (e.g., a drainage space) to reduce risk of moisture damage.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ASTM E2925-17, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

IRC®: R703.7.3, ASTM Chapter 44 (New)

Proponent: Craig Conner, representing self (craig.conner@mac.com); Joseph Lstiburek, representing self (joe@buildingscience.com)

2018 International Residential Code

Revise as follows:

R703.7.3 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-resistive, vapor-permeable barrier with a performance water resistance at least equivalent to two layers of Grade D paper or two layers of water-resistive barrier complying with ASTM E2556. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, is directed between the layers.

Exception: Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper a water-resistive barrier complying with ASTM E2556 Type I and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage foam plastic insulating sheathing layer or by a minimum 3/16 inch (5 mm) space.

Add new text as follows:

ASTM

F2556/F2556M—10: Standard Specification for Vapor Permeable Flexible Sheet Water-resistive Barriers Intended for Mechanical Attachment

Reason: Objective:

1. Define water resistance as the primary functional requirement of the WRB and remove reference to vapor permeable.
2. Enable a single layer of WRB complying with ASTM E2556 Type I with a drainage space.
3. Define depths drainage space

The existing code language gives insufficient guidance for other approved materials. The added language addresses this issue and provides a specific performance requirement for water resistance and provides consistancy with other sections of the code that relate specifically to water-resistive barriers.

The size of the drainage space needs to be specified. Type 1 is the appropriate water-resistive metric for the specified space. This logic is consistant with the body and intent of the text of Section R703.7.3. The specified space and one layer of Type 1 provides equivalent performance to the two layers of Type 1 specified in the body of R703.7.3.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change gives better guidance for water-resistance.

Staff Analysis: The referenced standard, ASTM E2556/E2556M-10, is currently referenced in other 2018 I-codes.
2018 International Residential Code

**R703.7.3 Water-resistive barriers.** Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-resistant, vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistant barrier, is directed between the layers.

**Exception-Exceptions:**

1. Where the water-resistant barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage space.

2. Where the water-resistant barrier is applied over wood-based sheathing where the annual mean rainfall as determined by the National Oceanic and Atmospheric Administration (NOAA) exceeds 20 inches, a minimum 3/16 inch space shall be provided between the stucco and the water-resistant barrier.

**Reason:** There are serious stucco failures occurring with wood frame buildings sheathed with wood based sheathing. The reasons for these failures can be found in the following link:

This code change addresses these issues. Annual mean rainfall is the appropriate metric for risk not humidity and temperature.

**Cost Impact:** The code change proposal will increase the cost of construction

The code change proposal reduces the cost of damage, repair and associated litigation. This change gives better guidance for water resistance.
RB245-19

IRC®: R703.7.3, ASTM Chapter 44 (New)

Proponent: Gary Ehrlich, National Association of Home Builders, representing National Association of Home Builders (gehrlich@nahb.org)

2018 International Residential Code

Revise as follows:

R703.7.3 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-resistive, vapor-permeable barrier with a performance that have a water resistance at least equivalent to 60-minute Grade D paper or other material complying with ASTM E2556, Type II and be separated from the stucco by an intervening, substantially nonwater-absorbing layer or by a designed drainage space not less than 3/16 inch in depth.

Exception: In climate zones designated as Dry (B) in accordance with Section 1101.7, the water-resistive barrier shall have a water resistance at least equivalent to that of two layers of 10-minute Grade D paper or other material complying with ASTM E2556, Type I. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, is directed between the layers. The designed drainage space or additional substantially non water-absorbing layer shall not be required.

Exception: Where the water-resistive barrier that is applied over wood based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially non water-absorbing layer or designed drainage space.

Add new text as follows:

ASTM

E2556-10: Standard Specification for Vapor Permeable Flexible Sheet Water-resistant Barriers Intended for Mechanical Attachment

Reason: The purpose of this code change is to revise the requirements for water resistive barriers and drainage behind exterior lath and plaster (stucco)

Significant water damage has occurred in stucco walls due to improper provisions for drainage and drying behind the lath and plaster. If sufficient amounts of moisture accumulate, especially around penetrations and rough openings, it may be able to wick through the traditional 10-minute layers of Grade D paper or equivalent material. The current exception for one layer of minimum 60-minute Grade D paper or equivalent with an additional layer of non-water-absorbing material or drainage space is a good recommended practice and is elevated to the base requirement. The traditional requirement for two 10-minute layers of Grade D paper or equivalent material is limited to dry climate zones where bulk moisture is not expected to be present for extended periods of time.

Materials considered as “substantially non-water-absorbing material” include an additional layer of 10-minute Grade D paper, an additional layer of housewrap, or foam plastic insulating sheathing.

Cost Impact: The code change proposal will increase the cost of construction

Depending on the products selected to meet the water-resistant barrier requirements, the cost to provide a
single 60-minute layer may be greater than the cost to provide two separate 10-minute layers. In warm-humid climates, the requirement for an additional 10-minute layer over the 60-minute layer would be an increase in cost if not already being provided as the "substantially non-water absorbing layer".

**Staff Analysis:** The referenced standard, ASTM E2556-10, is currently referenced in other 2018 I-codes.

Proposal # 5076

RB245-19
2018 International Residential Code

Revise as follows:

R703.7.3 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-resistive, vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper. The individual shall be installed as required in Table R703.7.3. The individual water-resistive barrier and bond break material layers shall be installed independently such that each layer provides a separate continuous plane and any flashing, installed in accordance with Section R703.4 and intended to drain to the water-resistive barrier, is directed between the layers.

Exception: Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage space.

</tbody>
</table>

a. Water-resistive barrier complying with Section R703.2 shall be 10-minute Grade D paper or have a water-resistance equal to or greater than one layer of water-resistive barrier complying with ADTM E2556, Type I.

b. Water-resistive barrier complying with Section R703.2 shall be 60-min Grade D paper or have a water-resistance equal to or greater than one layer of water-resistive barrier complying with ADTM E2556, Type II.

c. A minimum 1/8-inch (3.2 mm) draining space or have a minimum drainage efficiency of 90% as measured in accordance with ASTM E2273 or Annex A2 of ASTM E2925.
d. A minimum 3/16-inch (4.8 mm) ventilated drainage space and, where not a clear airspace, have a minimum drainage efficiency of 90% as measured in accordance with ASTM E2273 or Annex A2 of ASTM E2925.

e. Where foam plastic insulating sheathing complying with ASTM C578 or ASTM C1289 is located between the stucco and wood-based sheathing with a drainage space in accordance with footnote ‘c’, a ventilated drainage space is not required.

Add new definition as follows:

**BOND BREAK.** A substantially nonwater-absorbing layer placed directly behind stucco to prevent adhesion of the stucco to the surface of the water-resistive barrier, to serve as a protective layer over the water-resistive barrier, to provide a capillary break, and to promote drainage.

**DRAINAGE SPACE.** A separation between cladding and the surface of a water-resistive barrier created by a furred gap, channels, a porous material or matrix, or by other means to provide drainage of water downward to an outlet.

**VENTILATED DRAINAGE SPACE.** A drainage space that further incorporates the capability to allow outdoor air flow into and back out of the space behind cladding, usually by way of high and low vent inlets and outlets or by way of an air permeable, vented, cladding.

Add new text as follows:

**ASTM E2925-17:** Standard Specification for Manufactured Polymeric Drainage and Ventilation Materials Used to Provide a Rainscreen Function

**E2556/E2556M—10:** Standard Specification for Vapor Permeable Flexible Sheet Water-resistive Barriers Intended for Mechanical Attachment

**Reason:** The current minimum requirements for stucco installation over wood-based sheathing are confusing and also problematic in that they are predominantly aimed at practices that have been successful mainly in drying climates. In more moist climates, these minimum stucco installation requirements, particularly in regard to the WRB layer and lack of sufficient drainage or ventilation, has resulted in or contributed to numerous moisture-related problems.

Given the above concerns, this proposal achieves the following:

1) First, it **re-formats** the provisions into an easy-to-use tabulated (“look up table) format as shown in proposed Table R703.7.3. This will make it much easier to identify the various installation practices (including those also currently permitted in the code).

2) Second, it **clarifies** much of the confusion or ambiguity in this section of code. This is done through definitions and terminology that reflect the primary purpose of various features or materials that are important to an overall
stucco installation and proper functioning of the WRB layer. This has also allowed the exception to be deleted since it is now incorporated more appropriately within the requirements of Table R703.7.3 (and footnote ‘b’) and the added definition of a “bond break” (replacing currently use of “nonwater absorbing layer” is consistent with the intent of the exception as explained in the reason statement to proposal S93-03/04 which brought the exception into the 2006 code).

3) Third, it provides enhanced moisture control practices only where needed for the moist (rainy) and hot/humid climates where rainwater management (drainage) and also ventilation (drying) or hygric redistribution become more important, particularly when used over wood-based sheathing. Thus, these provisions add the enhancements only where needed and only where stucco is used over wood sheathing which is susceptible to moisture (following the current approach to single-out special requirements for application over wood-based sheathing). It does not change requirements where stucco has been performing successfully for decades.

4) Finally, this proposal provides for flexibility in meeting the requirements, including both prescriptive and performance requirements for drainage and ventilation in the footnotes. And, these requirements are consistent with a wide selection of suitable materials currently being used and relies on available (and widely used) consensus standards for measuring performance of those materials or alternatives.

**Cost Impact:** The code change proposal will increase the cost of construction

This proposal will not increase cost for stucco installation over substrates other than wood-based sheathing. Also, it will not impact cost or change requirements in dry climates where the minimum stucco installation over wood-based sheathing has a very successful performance record. Even where enhanced practices (drainage or ventilation) are required, this will impact cost only where they are not already being used to control risk of moisture damage. For those installations not already using these enhanced provisions in moist/rainy/humid climates, this proposal will likely reduce long term costs to builders and home owners because it will reduce risk of moisture problems and improve durability.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ASTM E2925-17, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

The referenced standard, ASTM E2556-10, is currently referenced in other 2018 I-codes.

2018 International Residential Code

Revise as follows:

R703.8.4 Anchorage. Masonry veneer shall be anchored directly to the supporting wall studs with corrosion-resistant metal ties embedded in mortar or grout and extending into the veneer a minimum of 1 1/2 inches (38 mm), with not less than 5/8-inch (15.9 mm) mortar or grout cover to outside face. Masonry veneer shall conform to Table R703.8.4(1). For Where the masonry veneer tie attachment is fastened directly to wood structural panel not less than 7/16 performance category through insulating sheathing not greater than 2 inches (51 mm) in thickness, see Table R703.8.4(2). Where Table R703.8.4(2) is used, attachment to the wood studs behind the sheathing is not required.

Reason: This is a non-technical change. It clarifies the code making it easier to use and enforce, and making it more clearly conveys the two separate anchorage requirements -- one directly to the studs and one directly to wood structural panel sheathing.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal clarifies the code and will not increase the cost of construction.
2018 International Residential Code

Revis as follows:

<td>Minimum nominal 1 in. between sheathing and veneer</td>
</tr>
<tr>
<td>Cold-formed steel stud backing with adjustable metal strand wire</td>
<td>W2.8 (0.187 in. dia) with hook embedded in mortar joint&lt;sup&gt;e,f&lt;/sup&gt;</td>
<td>No. 10 screw extending through the steel framing a minimum of three exposed threads</td>
<td>Greater than 4 5/8 in. between backing and veneer</td>
</tr>
</tbody>
</table>

<sup>b</sup> All fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

<sup>c</sup> All fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

<sup>a</sup> In Seismic Design Category D0, D1 or D2, the minimum tie fastener shall be an 8d ring-shank nail (2 1/2 in. × 0.131 in.) or a No. 10 screw extending through the steel framing a minimum of three exposed threads.

<sup>d</sup> Adjustable tie pintle shall include a minimum of 1 pintle leg of wire size W2.8 (MW18) with a maximum offset of 1-1/4 in.

<sup>e</sup> Adjustable tie pintle shall include a minimum of 2 pintle legs with a maximum offset of 1-1/4 in. Distance between inside face of brick and end of pintle shall be a maximum of 2 in.
f. Adjustable tie backing attachment components shall consist of one of the following: eyes with minimum wire W2.8 (MW18), barrel with minimum 1/4 in. outside dia., or plate with minimum thickness of 0.074 in. and minimum width of 1-1/4 in.

**Reason:** This code change proposal allows larger airspaces to be constructed between masonry veneer and backing. Larger airspaces are necessary in order to accommodate thicker continuous insulation which may be needed in colder climate zones.

If adopted, the tie and airspace provisions of the IRC would match those required by the IBC through reference to the anchored masonry veneer provisions of TMS 402 Building Code Requirements for Masonry Structures. As such, they would allow masonry veneer with airspaces up to a maximum of 4-5/8 in. to be constructed using the traditional tie configurations already in the existing IRC table. They would also allow masonry veneer with airspaces greater than 4-5/8 in. up to a maximum of 6-5/8 in. to be constructed using stiffer tie configurations.

This code change proposal also adjusts the existing footnotes in the table (Footnotes a, b and c). For the footnote addressing Seismic Design Category D0, D1 or D2, there is no need to include No. 10 screws as they are already required for all cold-formed steel framing. Footnotes addressing rust-inhibitive coating and construction mortar are moved to more appropriate locations.

**Cost Impact:** The code change proposal will increase the cost of construction

This code change proposal WILL NOT increase the cost of constructing masonry veneer with an airspace of 4-1/2 in. or smaller as currently allowed by the existing code provision. Rather, it allows the construction of masonry veneer with an airspace larger than 4-1/2 in. to a maximum of 6-5/8 in. However, masonry veneer with an airspace greater than 4-5/8 in. will be more expensive than veneer with an airspace of 4-5/8 in. or less because stiffer ties are required to span the larger airspace.

Proposal # 5503

a. Linear interpolation is permitted.

b. The table values are based on a maximum 30-foot mean roof height, and effective wind area of 10 square feet Wall Zone 5 (corner), and the ASD design component and cladding wind pressure from Table R301.2(2), adjusted for exposure in accordance with Table R301.2(3), multiplied by the following adjustment factors: 2.6 (Case 1) and 3.7 (Case 2) for wind speeds less than 130 mph and 3.7 (Case 2) for wind speeds greater than 130 mph.

c. Gypsum wallboard, gypsum panel product or equivalent.

d. For the indicated wind speed condition, vinyl siding over foam sheathing, only on the exterior of frame walls with vinyl siding is not allowed unless the vinyl siding complies with an adjusted minimum design wind pressure requirement as determined in accordance with Note b and the wall assembly shall be capable of resisting an impact without puncture at least equivalent to that of a wood frame wall with minimum 7/16-inch OSB sheathing as tested in accordance with ASTM E1886. The vinyl siding shall comply with an adjusted design wind pressure requirement in accordance with Note b, using an adjustment factor of 2.67.

**Reason:** The main purpose of this proposal is to update Table R703.11.2 to ensure that the adjusted vinyl siding design wind pressure ratings are based on updated standard for vinyl siding (ASTM D3679) which has changed the pressure equalization factor from 0.36 to 0.5 for design wind pressure rating of vinyl siding. Because the pressure equalization factor in ASTM D3679 is now more conservative (changed to 0.5 from 0.36), the adjustment for applications over foam sheathing are adjusted downward accordingly by multiplying existing table values by 0.36/0.5 = 0.72. This will ensure that the intended level of performance is maintained with use of newer vinyl siding products complying with ASTM D3679 as required by the code. Also, the design components and cladding wind pressures for walls (which the adjusted values in Table R703.11.2 are based) remain consistent with the newer ASCE 7-16 standard. The proposal also coordinates “wind load design pressure rating” with terminology as used in ASTM D3679.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal only updates to correlate with the newer ASTM D3679 standard. Because the adjustments are relative to that standard, there is no difference in cost of vinyl siding specified for use over foam sheathing.
RB250-19

Proponent: Matthew Dobson, Vinyl Siding Institute, representing Vinyl Siding Institute (mdobson@vinylsiding.org)

2018 International Residential Code

Revise as follows:

**R703.14 Polypropylene siding.** Polypropylene siding shall be certified and labeled as conforming to the requirements of ASTM D7254, and those of Section R703.14.2 or Section R703.14.3, by an approved quality control agency.

Delete without substitution:

**R703.14.2 Fire separation.** Polypropylene siding shall not be installed on walls with a fire separation distance of less than 5 feet (1524 mm) and walls closer than 10 feet (3048 mm) to a building on another lot.

  **Exception:** Walls perpendicular to the line used to determine the fire separation distance.

**R703.14.3 Flame spread index.** The certification of the flame spread index shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E84 or UL 723.

Reason: The requirements in sections R703.14.2 & 3, are unnecessary and unfair. Section R302 of the code deals with fire separation, specifically for high density settings. We feel these sections are erroneous for the following reasons:

1. 703.14.2 bans the use of polypropylene siding high density settings, yet the product can pass an ASTM E119 test which is the requirement in high density settings. The requirement also applies a 10 foot fire separation to buildings on another lot which may or may not be enforceable as there may be two property owners involved.

2. 703.14.3 provides that if you change how you conduct the flame spread test prescribed in the ASTM standard for polypropylene siding, it can be used in high density settings. Having changes to standard testing methods in the code is inappropriate. This issue has been ongoing in the ASTM realm for years, it not the place of the code to get in the middle of this issue. Further, there has been no shown direct correlation of how this specific change to the flame spread test impacts allowing the product’s use in high density settings, especially when the long standing requirement has been the rated assembly test.

We have included as evidence a report which approves polypropylene siding use with an ASTM E119 rated assembly as required by the code and therefore could and should be allowed in high density settings.

The code should be fair in its approach and not single out one particular product without clear substantiated evidence. We ask these erroneous restrictions be removed and let the code regulate safely as it has done through section R302.

Cost Impact: The code change proposal will decrease the cost of construction This change could potentially reduce the cost by removing an additional unnecessary testing requirement.

Proposal # 5461

RB250-19
2018 International Residential Code

Revise as follows:

**TABLE R703.15.1**

| CLADDING MINIMUM FASTENING REQUIREMENTS FOR DIRECT ATTACHMENT OVER FOAM PLASTIC SHEATHING TO SUPPORT CLADDING WEIGHT<sup>a</sup> |
| --- | --- | --- |
| **MA**: FOAM | 16 | Hor Sp |
| **Fa**: Cla Wt |
| **Wt**: 3 psf | 1 psi |

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

DR = Design Required.

**o.c.** = On Center.

a. Wood framing shall be Spruce-pine-fir or any wood species with a specific gravity of 0.42 or greater in accordance with AWC NDS.

b. Where wood structural panels complying with the specific gravity requirement of Note 'a' are used, the fastener penetration depth into framing plus the thickness of the such panel shall be considered as satisfying the minimum penetration into framing. For cladding connections to wood structural panels, see Table R703.3.3.

c. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths.

d. Foam sheathing shall have a minimum compressive strength of 15 psi in accordance with ASTM C578 or ASTM C1289.

**Reason:** This footnote added to Table R703.15.1 is needed to coordinate with provisions in other parts of the code related to fastening through wood structural panels which addresses a very common “oversheathing” application of foam plastic insulating sheathing (continuous insulation).
Cost Impact: The code change proposal will decrease the cost of construction.
The proposal will allow for slightly reduced fastener lengths while still satisfying minimum fastener penetration. It will also help reduce cost by referring to Table R703.3.3 which permits fastening directly to wood-structural panels of minimum required thickness to serve as a nail base. This will also simplify installation which can reduce cost.
### 2018 International Residential Code

**R703.15.1 Direct attachment.** Where cladding is installed directly over foam sheathing without the use of furring, cladding minimum fastening requirements to support the cladding weight shall be as specified in Table R703.15.1.

Revise as follows:

</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 mil = 0.0254 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

DR = Design Required.

o.c. = On Center.

- Wood furring shall be Spruce-pine-fir or any softwood species with a specific gravity of 0.42 or greater. Steel furring shall be minimum 33-ksi steel. Steel studs shall be minimum 33-ksi steel for 33-mil and 43-mil thickness, and 50-ksi steel for 54-mil steel or thicker.
- Screws shall comply with the requirements of ASTM C1513.
- Where the required cladding fastener penetration into wood material exceeds \( \frac{3}{4} \) inch and is not more than 1\( \frac{1}{2} \) inches, a minimum 2-inch nominal wood furring or an approved design shall be used.
- Foam sheathing shall have a minimum compressive strength of 15 psi in accordance with ASTM C578 or ASTM C1289.
e. Furring shall be spaced not more than 24 inches (610 mm) on center, in a vertical or horizontal orientation. In a vertical orientation, furring shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, the indicated 8-inch and 12-inch fastener spacing in furring shall be achieved by use of two fasteners into studs at 16 inches and 24 inches on center, respectively.

**Reason:** This code change proposal adds a 15 psf column option to the cladding over foam plastic sheathing tables. This is the weight usually associated with adhered masonry veneer applied using a traditional lath and scratch coat. The thicknesses in the proposed 15 psf columns were developed using the same analysis that was used for developing the original tables.

**Cost Impact:** The code change proposal will decrease the cost of construction. This code change proposal decreases the cost of hiring an engineer to determine the size and spacing of fasteners for a 15 psf cladding directly attached over foam sheathing.
Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee of the American Chemistry Council

2018 International Residential Code

For SI: 1 inch = 25.4 mm, 1 mil = 0.0254 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

DR = Design Required.

o.c. = On Center.

a. Steel framing shall be minimum 33 ksi steel for 33 mil and 43 mil steel, and 50 ksi steel for 54 mil steel or thicker.

b. Where cladding is attached to wood structural panel sheathing only, fastening requirements shall be in accordance with Table R703.3.3.

c. Screws shall comply with the requirements of ASTM C1513.
Foam sheathing shall have a minimum compressive strength of 15 psi in accordance with ASTM C578 or ASTM C1289.

**Reason:** This footnote added to Table R703.16.1 is needed to coordinate with provisions in other parts of the code related to fastening through wood structural panels which addresses a very common “oversheathing” application of foam plastic insulating sheathing (continuous insulation).

**Cost Impact:** The code change proposal will decrease the cost of construction.

The proposal will help reduce cost by referring to Table R703.3.3 which permits fastening directly to wood-structural panels of minimum required thickness to serve as a nail base. This will also simplify installation which can reduce cost.

Proposal # 4530

---

RB254-19
2018 International Residential Code

Revise as follows:

R802.1.5 Fire-retardant-treated wood. Fire-retardant-treated wood (FRTW) is any wood product that, when impregnated with chemicals by a pressure process or other means during manufacture, shall have, when tested in accordance with ASTM E84 or UL 723, a listed flame spread index of 25 or less and does not show evidence of significant progressive combustion where the test is ... In addition, the ASTM E84 or UL 723 test shall be continued for an additional 20-minutes. In addition, and the flame front shall not progress more than 10.5 feet (3200 mm) beyond the center line of the burners at any time during the extended 30-minute test.

Reason: This proposal addresses the incorrect double requirement for testing to both flame front progress and no significant progressive combustion in the extended ASTM E84 test. This issue has been under discussion for many years at the ICC codes, as well as at ASTM and at NFPA, but can now be resolved in the IRC code. The ASTM E5 committee, responsible for ASTM E84, has now, for the first time, accepted incorporating requirements for conducting a 30 minute test. Until this change ASTM E84 did not contain any information other than that it is a 10 minute test. Consequently, until this change ASTM E84 did not provide any details on how to assess either "no evidence of significant progressive combustion" or "the flame front shall not progress more than 101/2 feet (3200 mm) beyond the centerline of the burners". The information for how to determine both of those characteristics is contained in ASTM E2768. The committee agreed that the next edition of ASTM E84 will state that a 30 minute test is to be conducted per ASTM E2768. In turn, ASTM E2768 explains that "no significant progressive combustion" is evidenced by lack of flame front progress beyond 10 1/2 feet. In fact ASTM E2768 states: "The flame front shall not progress more than 10.5 ft (3.2 m) beyond the centerline of the burners at any time during the 30 min test period. This is considered evidence of no significant progressive combustion in this test method." This IBC proposal incorporates the requirements from the ASTM E84 test into the IBC and ensures that the code does not require a duplicate (and confusing) measurement.

It is likely that information will be presented stating that "no significant progressive combustion" has been in the code since the legacy codes and that the flame front progress requirement was added later. That is exactly the reason that ASTM E2768 was developed to ensure that everyone understands what is to be measured, and that is what the testing laboratories have been doing for many years now.

This change appears to alter requirements but in fact simply recognizes what the ASTM E84 standard states and what the labs are doing (and have been doing for years) and, therefore, is really clarification.

The ASTM E05 committee agreed on actions at the December 2018 meeting so that the language in ASTM E84 reads:

1. Scope

1.1 This fire-test–response standard for the comparative surface burning behavior of building materials is applicable to exposed surfaces such as walls and ceilings. The test is conducted with the specimen in the ceiling position with the surface to be evaluated exposed face down to the ignition source. The material, product, or assembly shall be capable of being mounted in the test position during the test. Thus, the specimen shall either be self-supporting by its own structural quality, held in place by added supports along the test surface, or
secured from the back side.

1.2 Test Method E84 is a 10-minute fire-test response method. The following standards address testing of materials in accordance with test methods that are applications or variations of the test method or apparatus used for Test Method E84:

1.2.1 Materials required by the user to meet an extended 30-min duration tunnel test shall be tested per Test Method E2768.

1.2.2 Wires and cables for use in air-handling spaces shall be tested per NFPA 262.

1.2.3 Pneumatic tubing for control systems shall be tested per UL 1820.

1.2.4 Combustible sprinkler piping shall be tested per UL 1887.

1.2.5 Optical fiber and communications raceways for use in air handling spaces shall be tested per UL 2024.

1.3 The purpose of this test method is to determine the relative burning behavior of the material by observing the flame spread along the specimen. Flame spread and smoke developed index are reported. However, there is not necessarily a relationship between these two measurements.

1.4 The use of supporting materials on the underside of the test specimen has the ability to lower the flame spread index from those which might be obtained if the specimen could be tested without such support. These test results do not necessarily relate to indices obtained by testing materials without such support.

1.5 Testing of materials that melt, drip, or delaminate to such a degree that the continuity of the flame front is destroyed, results in low flame spread indices that do not relate directly to indices obtained by testing materials that remain in place.

1.6 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.7 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes, excluding those in tables and figures, shall not be considered as requirements of the standard.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This simply recognizes what the fire test labs have been doing for many years. When they conduct the "extended ASTM E84 test" they assess two criteria: a flame spread index of 25 and a flame front that does not progress more than 10.5 ft (3.2 m) beyond the centerline of the burners.

Proposal # 5094

RB255-19
2018 International Residential Code

Revise as follows:

R802.1.5.2 Other means during manufacture. For wood products produced impregnated with chemicals by other means during manufacture, the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product. The use of paints, coatings, stains or other surface treatments is not an approved method of protection as required in this section.

Reason: This proposal corrects the language of the section by making it identical to the language of the corresponding section of the IBC. The proposal makes two changes:
1. It incorporates the words "impregnated with chemicals" into the first sentence, which makes it consistent with the code section above that says that the pressure treatment process must provide impregnation with chemicals.
2. It adds a sentence pointing out that coatings are not permitted as a way of generating fire retardant treated wood.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is clarification, consistent with the IBC and with the section above.
Proponent: Manny Muniz, representing Representing self (Mannymuniz.mm@gmail.com)

2018 International Residential Code

Revise as follows:

R802.1.5.2 Other means during manufacture. For wood products produced impregnated with chemicals by other means during manufacture, the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product. The use of paints, coating, stains or other surface treatments is not an approved method of protection as required by this section.

Reason: The proposed code language has already been approved in the IBC and appears in the 2018 International Building Code, Section 2303.2.2. Clarification is made that regardless of the other means used during manufacture, fire-retardant-treated wood must be impregnated with chemicals per the definition of fire-retardant-treated wood in Chapter 2. During the IBC committee hearings, the State Fire Marshal of California, a committee member, identified this code change as being a necessary clarification as California had experienced numerous problems with coated wood products pretending to be fire-retardant-treated wood. The language in the last sentence was derived from the California codes.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The code change proposal will not increase or decrease the cost of construction.

Proposal # 5590

RB633
RB258-19
IRC: R802.1.5.3, 802.1.5.3.1 (New)

Proponent: Marcelo Hirschler, representing GBH International (mmh@gbhint.com)

2018 International Residential Code
Revise as follows:

R802.1.5.3 Testing. For wood products produced by other means during manufacture, other than a pressure process, all sides—fire retardant treated wood products the front and back faces of the wood product shall be tested in accordance with and produce the results required in Section R802.1.5. Testing of only the front and back faces of wood structural panels shall be permitted.

Add new text as follows:

R802.1.5.3.1 Fire testing of wood structural panels. Wood structural panels shall be tested with a ripped or cut longitudinal gap of 1/8 inch (3.2 mm).

Reason: Note that the sections above require that fire retardant treated wood be "impregnated with chemicals" and provide permanent protection. That requirement applies to all FRTW products, whether produced by a pressure process or produced by other means during manufacture. IBC Section 2303.2.2 (and the proposed revision to R802.1.5.2, for consistency) is also explicit in stating that the use of paints or coatings is not an approved method to comply with this section. This proposal thus eliminates the requirement to test a particular type of fire retardant treated wood on "all sides", since the testing is never actually conducted on all sides (as pointed out often by multiple testifiers in previous code cycles) because all sides really means front and back (you literally cannot test the edges in the ASTM E84 other than by putting multiple edge pieces into the tunnel to make up the 24 feet by 2 feet specimen). In order to test "all sides" of a lumber product it would be necessary to fasten 864 small pieces together to make one specimen, which is not realistic.

The proposed new subsection will add fire safety because it recognizes an issue that was highlighted in the previous code cycle, and was also brought up in committee ASTM E05 and at the IWUIC: wood structural panels are typically installed in the field following industry practice. Industry recommendations for wood structural panels require a gap to accommodate dimensional changes caused by swelling due to changing moisture conditions. Therefore, installation in the field requires cutting and ripping of the panels and this results in the creation of "non-factory edges". Therefore, it is important to test wood structural panels with a rip or gap to ensure that the required fire test results from the charging paragraph are achieved when the interior of the panel is exposed.

Note that the IWUIC requires such a rip or gap for ignition resistant structural panels, and it sends FRTW products to IBC section 2303.2, which is equivalent to section R802.1.5.

Cost Impact: The code change proposal will increase the cost of construction
This proposal will add fire safety and will require more testing for wood structural panels. The proposal will also require more testing for other FRTW products manufactured by a pressure process but apparently less testing for FRTW products that are manufactured by other means, except that typically just the front and back faces are tested anyway.

Proposal # 4823

RB258-19
RB259-19
IRC®: R801.2, ASSE Chapter 44 (New)

Proponent: nella davis-ray, Michigan Department of Licensing and Regulatory Affairs, MIOSHA, representing MIOSHA (davis-rayn@michigan.gov)

2018 International Residential Code
Revise as follows:

R801.2 Requirements. Roof and ceiling construction shall be capable of accommodating all loads imposed in accordance with Section R301 and of transmitting the resulting loads to the supporting structural elements. Permanent anchorage connectors shall be installed to fixed structural members to provide a secure connecting point for personal fall arrest systems. The anchorage connecting devices shall comply with ANSI/ASSE Z359.1.

Add new text as follows:

ANSI/ASSE Z359.1—2016: Requirements for the ANSI/ASSE Z359 Fall Protection Code

Reason: Falls are the leading cause of death in the construction industry. Falls from roofs account for a third of the fall deaths. Contractors are required to use fall protection by OSHA. 1926.502 - Fall Protection, addresses minimum requirements and criteria for fall protection at construction workplaces. Personal fall arrest systems (PFAs) require a secure point of attachment, anchorage and components for coupling PFAs to anchorage, anchorage connectors. A significant challenge contractors report is finding or creating suitable anchoring for PFAs. A logical time to install anchorage connectors is during the construction process. OSHA cannot mandate permanent anchorage connectors for PFAs fabricated or designed into fixed structural members although we know the protective and functional anchoring role they play.

A variety of permanent anchorage connectors are commercially available. ANSI/ASSE Z359 establishes safety requirements for personal fall arrest systems, subsystems and components. Verification that permanent anchorage connectors are installed in accordance with applicable requirements of ANSI/ASSE Z359.1 will be an additional element of a building plan review.

Requiring permanent anchorage connectors has many advantages:

a. Level playing field: Currently, installing and removing temporary anchor points costs the “safe” contractors time and money. If the building code required the installation permanent anchorage connectors it would help ensure compliance with fall protection requirements.

b. Benefits to the building owner. The building owners becomes the beneficiary of a safer building which is a primary goal of construction codes. Permanent anchorage connections came be used for building maintenance such as cleaning windows, cleaning gutters, minor repairs, hanging holiday lights, etc. These anchor points would be available for maintenance/repair contractors eliminating the need for these contractors to make new penetrations in the roof.

c. Reduced labor costs: The labor cost of installing and removing temporary anchors is eliminated, helping offset the cost of the permanent anchors.
d. Efficiencies in construction: For other contractors working at the site, the work and costs of installing temporary anchor points is removed. This added efficiency would likely help offset the cost of the permanent anchorage connectors.

e. Workers Comp Reductions: Workers compensation costs for the building industry is very high. Availability of anchor points, and their use, may lead to lower premium costs for many businesses.

f. General Liability: Reduced likelihood of accidents by contractors, and due diligence for providing safety, reduces property and personal injury risk thus reducing the contractor and building owner liability.

g. Aligning requirements: Aligning building code requirements with national safety requirements helps contractors more clearly understand what is required and how it all fits together.

h. Increased use of fall protection: If the anchorage connectors are there, people are more likely to use them. Creating buildings and job sites with less risk, less citations, and more cost savings.

**Cost Impact:** The code change proposal will increase the cost of construction
The increased advantage of having anchorage will encourage use of fall protection which will lower fall accidents and fatalities. In turn, increased safety may lower worker compensation costs.

**Staff Analysis:** The referenced standard, ANSI/ASSE Z359.1—2016, is currently referenced in other 2018 I-codes.
2018 International Residential Code

Revise as follows:

R802.4.2 Framing details. Rafters shall be framed opposite from each other to a ridge board, shall not be offset more than 1 1/2 inches (38 mm) offset from each other to a ridge board or directly opposite from each other and shall be connected with a collar tie, gusset plate or ridge strap in accordance with Section R802.4.6 or a gusset plate in accordance with Table R602.3(1). Rafters shall be nailed to the top wall plates in accordance with Table R602.3(1) unless the roof assembly is required to comply with the uplift requirements of Section R802.11.

R802.4.6 Collar ties. Where collar ties are used to connect opposing rafters, they shall be located in the upper third of the attic space and fastened in accordance with Table R602.3(1). Collar ties shall be not less than 1 inch by 4 inches (25 mm × 102 mm) nominal, spaced not more than 4 feet (1220 mm) on center. Ridge straps in accordance with Table R602.3(1) shall be permitted to replace collar ties. Ridge straps shall be not less than 1 1/4 inch (32 mm) x 20 gage and shall extend a minimum of 12 inches (305 mm) onto rafters and shall be nailed in accordance with manufacturers installation instructions.

**TABLE R602.3(1)**

<table>
<thead>
<tr>
<th>ITEM</th>
<th>DESCRIPTION OF BUILDING ELEMENTS</th>
<th>NUMBER AND TYPE OF FASTENERᵃ,ᵇ,ᶜ</th>
<th>SPACING AND LOCATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Collar tie to rafter, face nail or 1 1/4” × 20 ga. ridge strap to rafter</td>
<td>4-10d box (3” × 0.128”); or 3-10d common (3” × 0.148”); or 4-3” × 0.131” nails</td>
<td>Face nail each rafter</td>
</tr>
</tbody>
</table>

Reason: Prior to the 2012 code, this section (R802.3.1 in the previous code) simply called out a "ridge strap" with no further information. It was not known to most code users that Table R602.3(1) showed a "1 1/4" x 20 ga ridge strap". A proposal was submitted and approved to modify this section to include "..in accordance with Table R602.3(1)." and Figure R802.4.5 was also revised to call out the ridge strap which tied those sections together.

However, upon further examination, I realized that the ridge strap noted in the Table only defines the width and gauge of the strap. It does not specify the length that the strap has to extend onto the rafter or the nailing requirements for the strap. It also does not specify the spacing requirements for the straps. Without this information, the strap reference is incomplete and, effectively, impossible to accomplish.

This proposal is to address the missing information. Rather than adding the information to the strap noted in the table, it would be much more clear to add the information to the text of Sections R802.4.2 and R802.4.6 as shown in this proposal.

The requirement for a minimum of 12 inches onto each rafter is based on typical manufactured straps.
The spacing requirement is consistent with the collar tie requirement of 48 inches on center.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This proposal clarifies an existing provision for ridge straps to replace collar ties and does not add or remove any code requirements. The use of ridge straps is and remains an option. Therefore, there is no cost impact.

Proposal # 4090

RB260-19
R802.5.2 Ceiling joist and rafter connections. Ceiling joists, rafter ties and ridge beams shall be in accordance with Sections R802.5.2.1 and R802.5.2.2.

Revise as follows:

R802.5.2 R802.5.2.1 Ceiling joist and rafter connections. Joists parallel to rafters. Where ceiling joists run parallel to rafters and are located at the top wall plate, they shall be connected to rafters at and the top wall plate in accordance with Table R802.5.2 R802.5.2.1. Where ceiling joists are not connected to the rafters at the top wall plate, they shall be installed in the bottom third of the rafter height in accordance with Figure R802.4.5 and Table R802.5.2 R802.5.2.1. Where the ceiling joists are installed above the bottom third of the rafter height, the ridge shall be supported by a wall or ridge beam designed in accordance with accepted engineering practice as a beam. Where ceiling joists do not run parallel to rafters, the ceiling joists shall be connected to top plates in accordance with Table R602.3(1). Each rafter shall be tied across the structure with a rafter tie or a 2-inch by 4-inch (51 mm × 102 mm) kicker connected to the ceiling diaphragm with nails equivalent in capacity to Table R802.5.2.

TABLE R802.5.2 R802.5.2.1
RAFTER/CEILING JOIST HEEL JOINT CONNECTIONS\(a, b, c, d, e, g\)

<table>
<thead>
<tr>
<th>RAFTER SLOPE</th>
<th>RAFTER SPACING (inches)</th>
<th>GROUND SNOW LOAD (psf)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>20(f)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Roof span (feet)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Required number of 16d common nails(a, b) per heel joint splices(c, d, e)</td>
</tr>
</tbody>
</table>

Add new text as follows:

R802.5.2.2 Ceiling joists not parallel to rafters or not provided. Where ceiling joists do not run parallel to rafters, the ceiling joists shall be connected to top plates in accordance with Table R602.3(1). Each rafter shall be tied across the structure with a rafter tie not less than 2 inches by 4 inches (51 mm × 102 mm) fastened to rafters in accordance with Table R802.2.5.1 and with joints in accordance with Section R802.5.3. Where ceiling joists or rafter ties are not provided, the ridge shall be supported by a wall or ridge beam designed in accordance with accepted engineering practice.

Revise as follows:

R802.5.2.4 R802.5.3 Ceiling joists lapped. Ends of ceiling joists shall be lapped not less than 3 inches (76 mm) or butted over bearing partitions or beams and toenailed to the bearing member. Where ceiling joists are used to provide resistance to rafter thrust, lapped joists shall be nailed together in accordance with Table.
R802.5.2 and butted joists shall be tied together with a connection of equivalent capacity in a manner to resist such thrust. Joists that do not resist thrust shall be permitted to be nailed in accordance with Table R602.3(1). Wood structural panel roof sheathing, in accordance with Table R503.2.1.1(1), shall not cantilever more than 9 inches (229 mm) beyond the gable endwall unless supported by gable overhang framing.

Delete without substitution:

R802.5.2.2 Rafter ties. Wood rafter ties shall be not less than 2 inches by 4 inches (51 mm x 102 mm) installed in accordance with Table R802.5.2 at each rafter. Other approved rafter tie methods shall be permitted.

Revise as follows:

R802.5.2.3 R802.5.4 Blocking: Lumber. Blocking Lumber used to transfer loads shall be not less than utility grade lumber.

Reason: The purpose of this code change is to clarify the requirements for connections of rafters and ceiling joists. This section is the most important section in establishing the concept of the continuous tie across the lower portion of the rafters, using either ceiling joists or rafter ties, which will prevent the rafters from sliding off the walls or pushing the walls out when the rafters are loaded, which is referred to as rafter thrust. The concept is that the ceiling joists have to be installed in the lower portion of the attic, and fastened in a specific manner as required in Table R802.5.2. However, sometimes the ceiling joists are installed higher in the attic where they are ineffective as a tie, sometimes the ceiling joists are installed perpendicular to the rafters, and sometimes there may not be any ceiling joists at all, such as in a cathedral ceiling.

So the first revision is to break out these possibilities into two separate sections to clarify what needs to happen in each case to ensure the rafters do not slide off the walls or push them outward.

In each case, either a tie can be provided, or a "wall or ridge beam designed in accordance with accepted engineering practice" can be provided. This language is close to what was required in this section prior to the 2018 edition.

In new R802.5.2.2, the requirements for rafter ties are moved back into this section, and the description of the rafter tie is provided. Since it is in this section now, the subsequent section on Rafter Ties can be deleted. The language about the kicker connected to the ceiling diaphragm is deleted because I don't know what a kicker really is in regard to ceiling joists, and because a prescriptive requirement is not provided. Any alternate method could be accepted if proven equivalent.

In new R802.5.3, Ceiling Joists Lapped, the last sentence talking about wood structural panel roof sheathing is deleted because this is out of place. The exact same wording is repeated in Section R803.2.3, which is the appropriate location.

In the last section, the term "blocking" was replaced by "lumber". It does not appear that the term "blocking" is used anywhere in this section, but it is possible that scabs of wood could be used to transfer tension loads across butt joints in ceiling joists or rafter ties, so it is proposed to be left in this way.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. There is no intent to cause any change in requirements, just a clarification.

Proposal # 5688

</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. 10d common (3” × 0.148") nails shall be permitted to be substituted for 16d common (3-1/2”x 0.162") nails where the required number of nails is taken as 1.2 times the required number of 16d common nails.

b. Heel joint connections are not required where the ridge is supported by a load-bearing wall, header or ridge beam.

c. Where intermediate support of the rafter is provided by vertical struts or purlins to a load-bearing wall, the tabulated heel joint connection requirements shall be permitted to be reduced proportionally to the reduction in span.

d. Equivalent nailing patterns are required for ceiling joist to ceiling joist lap splices.

e. Applies to roof live load of 20 psf or less.

f. Tabulated heel joint connection requirements assume that ceiling joists or rafter ties are located at the bottom of the attic space. Where ceiling joists or rafter ties are located higher in the attic, heel joint connection requirements shall be increased by the following factors:

<table>
<thead>
<tr>
<th>( \frac{H_C}{H_R} )</th>
<th>Heel Joint Connection Adjustment Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \frac{1}{3} )</td>
<td>1.5</td>
</tr>
<tr>
<td>( \frac{1}{4} )</td>
<td>1.33</td>
</tr>
<tr>
<td>( \frac{1}{5} )</td>
<td>1.25</td>
</tr>
<tr>
<td>( \frac{1}{6} )</td>
<td>1.2</td>
</tr>
<tr>
<td>1/10 or less</td>
<td>1.11</td>
</tr>
</tbody>
</table>

where:

\( H_C = \) Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

\( H_R = \) Height of roof ridge measured vertically above the top of the rafter support walls.

g. Tabulated requirements are based on 10 psf roof dead load in combination with the specified roof snow load.
and roof live load.

**Reason:** Replace Table R802.5.2 to be consistent with calculation basis of 2018 Wood Frame Construction Manual (WFCM) heel joint nailing requirements based on the 2018 National Design Specification for Wood Construction (NDS) provisions for nailed connections. The reduced number of 16d common nails required in rafter tie connections, by approximately 15%, are due to changes in penetration factor and load duration assumptions from those used to develop the existing table. The existing table used a 0.77 penetration factor (based on 1991 and 1997 NDS) for 16d common nails with less than 12d penetration in the main member and a load duration factor of 1.25 for all tabulated cells. The proposed revised nailing requirements are based on use of a 1.15 load duration factor for snow cases, 1.25 load duration factor for roof live load cases, and an effective penetration factor equal to 1.0 per 2001 NDS and later editions when nail lateral value calculations are based on the actual penetration in the wood member. The ratio of nail design values for snow cases originally used to develop nailing requirements to the current nail design values for snow cases is \((Z \times 0.77 \times 1.25)/(Z \times 1.0 \times 1.15) = 0.84\) and explains the reduced number of nails required by this proposal. Due to revised nail design provisions in the NDS, the benefit of a longer nail that is clinched is no longer recognized for this application and existing footnote b is removed. A 10d common nail option is added in new footnote “a.” based on NDS lateral nail calculations. The table heading clarifies the 10psf dead load basis of the tabulated nailing requirements.

**Cost Impact:** The code change proposal will decrease the cost of construction
This code change utilizes fewer nails from the WFCM at less cost.

Proposal # 4258

_____________________________________________________
RB262-19
2018 International Residential Code

Revise as follows:

R802.5.2.1 Ceiling joists lapped. Ends of ceiling joists shall be lapped not less than 3 inches (76 mm) or butted over bearing partitions or beams and toenailed to the bearing member. Where ceiling joists are used to provide resistance to rafter thrust, lapped joists shall be nailed together in accordance with Table R802.5.2 and butted joists shall be tied together in a manner to resist such thrust. Joists that do not resist thrust shall be permitted to bel nailed in accordance with Table R602.3(1).

Wood structural panel roof sheathing, in accordance with Table R503.2.1.1(1), shall not cantilever more than 9 inches (229 mm) beyond the gable endwall unless supported by gable overhang framing.

Reason: This wording does not appear to belong here. This section deals with lapping of ceiling joists to provide a continuous tie across the building. The exact same text on roof sheathing cantilever over gable end walls is contained in Section R803.2.3.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is just deleting an unrelated and duplicate code requirement so no cost impact.
2018 International Residential Code

Revise as follows:

**R802.6 Bearing.** The ends of each rafter or ceiling joist shall have not less than 1 1/2 inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on masonry or concrete. The bearing on masonry or concrete shall be direct, or a sill plate of 2-inch (51 mm) minimum nominal thickness shall be provided under the rafter or ceiling joist. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 mm²). Where the roof pitch is greater than or equal to 3:12 (25% slope), and ceiling joists or rafter ties are connected to rafters to provide a continuous tension tie in accordance with Section R802.5.2, vertical bearing of the top of the rafter against the ridge board shall satisfy this bearing requirement.

**Reason:** The reason for this code change is to clarify what types of bearing are acceptable for rafters, specifically at the top ends of rafters. Section R802.6 requires that “The ends of each rafter or ceiling joist shall have not less than 1-1/2 inches of bearing on wood or metal.......”

Bearing is typically thought of as bearing on a horizontal surface, such as a top plate, beam, or hanger for resisting vertical loads. However, for a rafter system that has the continuous tension tie at the bottom provided by ceiling joists or rafter ties, and collar ties at the top, it is considered that the downward force is all transferred to the lower ends of the rafters, and the force at the top is a horizontal force toward the ridge board, bearing on it. So horizontal bearing here is fine.

On the other hand, when the roof slope gets shallow, a structural ridge beam is required to be provided. (See Section R802.4.4). In that case, the ridge beam is providing vertical support for the “top” end of the rafters, and a connection with vertical capacity is required (horizontal bearing).
Another case is when the horizontal tie is not provided at the bottom of the rafters. In that case, a load-bearing ridge beam is required to be provided (See Section R802.5.2). Again, here the ridge beam is providing vertical support for the top end of the rafter, so a support against vertical forces is required (horizontal bearing).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This code change is meant as a clarification, and will not result in an increase in cost for a normal rafter/ceiling joist system.
2018 International Residential Code

Revise as follows:

R802.11

Roof tie-down.

R802.11.1 Uplift resistance. Roof assemblies shall have uplift resistance in accordance with Sections R802.11.1.1 and R802.11.1.2.

Exception: Where the uplift force does not exceed 200 pounds (90.8 kg), rafters and trusses spaced not more than 24 inches (610 mm) on center Rafters or trusses shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1) where either of the following occur:

1. Where the uplift force per rafter or truss does not exceed 200 pounds (90.8 kg) as determined by Table R802.11.
2. Where the basic wind speed does not exceed 115 mph, the wind exposure category is B, the roof pitch is 5:12 (42-percent slope) or greater, and the roof span is 32 feet (9754 mm) or less, and rafters and trusses are spaced not more than 24 inches (610 mm) on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

R802.11.1.1 Truss uplift resistance. Trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as specified on the truss design drawings for the ultimate design wind speed as determined by Figure R301.2(5)A and listed in Table R301.2(1) or as shown on the construction documents. Uplift forces shall be permitted to be determined as specified by Table R802.11, if applicable, or as determined by accepted engineering practice.

R802.11.1.2 Rafter uplift resistance. Individual rafters shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by Table R802.11 or as determined by accepted engineering practice. Connections for beams used in a roof system shall be designed in accordance with accepted engineering practice.

Reason: The purpose of this proposal is to clarify the roof tiedown requirements. Section R802.11.1 states that roof tiedown shall be in accordance with either the truss tiedown section (R802.11.1.1) or the rafter tiedown section (R802.11.1.2). Then it has some more text that are actually exceptions for when the standard roof to wall fastening can be used. This seems to be more appropriate as an exception, so this code change is written as such. There is no intent to make technical changes. Exception 1 does not need the language about limiting to 24” o.c. since the uplift is being read directly form Table R802.11 anyway, and that only goes up to 24” o.c.

Cost Impact: The code change proposal will not increase or decrease the cost of construction This proposal is just a clarification of this section.
2018 International Residential Code

For SI: 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa.

**R804.3.2.1.2 Rake overhangs.** Rake overhangs shall not exceed 12 inches (305 mm) measured horizontally. The limitations provided for Option #1 or Option #2 in Figure R804.3.2.1.2. Outlookers at gable endwalls shall be installed in accordance with Figure R804.3.2.1.2. The required strength for uplift connectors required for Option #1 shall be determined in accordance with AISI S230 Table F3-4.

Delete and substitute as follows:
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**FIGURE R804.3.2.1.2**

**GABLE-ENDWALL-OVERHANG-DETAILS**
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R804.3.2.1.2
GABLE ENDWALL OVERHANG DETAILS

Revise as follows:

R804.3.2.5 Roof rafter bottom flange bracing. The bottom flanges of roof rafters shall be continuously braced, at a maximum spacing of 8 of 4 feet (2440 mm) as measured parallel to the roof rafters, with one of the following members:

1. Minimum 33-mil (0.84 mm) C-shaped member.
2. Minimum 33-mil (0.84 mm) track section.
3. Minimum 1 1/2-inch by 33-mil (38 mm by 0.84 mm) steel strap.

The bracing element shall be fastened to the bottom flange of each roof rafter with one No. 8 screw and shall be fastened to blocking with two No. 8 screws. Blocking shall be installed between roof rafters in-line with the continuous bracing at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the roof rafters.
The ends of continuous bracing shall be fastened to blocking or anchored to a stable building component with two No. 8 screws.

**Reason:** The purpose of this code change proposal is to update the cold-formed steel framing provisions of the International Residential Code to correspond to the latest edition of AISI S230 - *Standard for Cold-Formed Steel Framing - Prescriptive Method for One- and Two-Family Dwellings (AISI S230-18)*. The 2018 edition of AISI S230 has updated the prescriptive provisions to conform to the loading criteria of the 2016 edition of ASCE 7-16: *Minimum Design Loads and Associated Criteria for Buildings and Other Structures (ASCE 7-16)*. The cold-formed steel provisions affected by the update to ASCE 7-16 are exclusively located in IRC Section 804 – *Roof Framing*. The affected provisions are isolated in Section 804 due to the increase in wind pressure coefficients on roof surfaces from the 2010 to 2016 editions of ASCE 7. AISI S230-18 reduced the required bottom flange bracing spacing from 8-feet to 4-feet in order to minimize changes in the allowable roof span tables due to the increased wind loading.

There is a concurrent code change proposal to update Chapter 44 to AISI S230-18. A draft version of AISI S230-18 is currently available for review at www.aisistandards.org. AISI anticipates the final published edition of AISI S230-18 will be available free of charge at the same website by March 1, 2019.

**Bibliography:** AISI (2018), *Standard for Cold-Formed Steel Framing - Prescriptive Method for One- and Two-Family Dwellings*, ANSI/AISI S230-18, American Iron and Steel Institute, Washington D.C.

**Cost Impact:** The code change proposal will increase the cost of construction.

This proposal reduces the required bottom flange bracing of roof members to account for increase wind uplift forces. Also, in some conditions this code change proposal will require additional tie-downs at roof overhangs to resist wind uplift forces.

Proposal # 4002

RB266-19
2018 International Residential Code

Revise as follows:

R805.1 Ceiling installation. Ceilings shall be installed in accordance with the requirements for interior wall finishes as provided in Sections R702.1 through R702.6.

Reason: Removing section R702.7 from section R805 Ceiling Finishes clears up the confusion of vapor retarders being required in the ceiling assembly. Section R702.7 specifically requires vapor retarders for frame walls but since the ceiling finishes section refers to this section it may be interpreted to mean a vapor retarder is required in the ceiling assembly as well.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The code change proposal will not increase or decrease the cost of construction due to the fact the code is not changing but rather clarifying the scope as to how it is applied.
R806.1 Ventilation required. Enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof rafters shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain or snow. Ventilation openings shall have a least dimension of \(\frac{1}{16}\) inch (1.6 mm) minimum and \(\frac{1}{4}\) inch (6.4 mm) maximum. Ventilation openings having a least dimension larger than \(\frac{1}{4}\) inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth, perforated vinyl or similar material with openings having a least dimension of \(\frac{1}{16}\) inch (1.6 mm) minimum and \(\frac{1}{4}\) inch (6.4 mm) maximum. Openings in roof framing members shall conform to the requirements of Section R802.7. Required ventilation openings shall open directly to the outside air and shall be protected to prevent the entry of birds, rodents, snakes and other similar creatures.

Revision as follows:

R806.5 Unvented attic and unvented enclosed rafter assemblies. Unvented attics and unvented enclosed roof framing assemblies created by ceilings that are applied directly to the underside of the roof framing members and structural roof sheathing applied directly to the top of the roof framing members/rafters, shall be permitted where all the following conditions are met:

1. The unvented attic space is completely within the building thermal envelope.
2. Interior Class I vapor retarders are not installed on the ceiling side (attic floor) of the unvented attic assembly or on the ceiling side of the unvented enclosed roof framing assembly.
3. Where wood shingles or shakes are used, a minimum \(\frac{1}{4}\)-inch (6.4 mm) vented airspace separates the shingles or shakes and the roofing underlayment above the structural sheathing.
4. In Climate Zones 5, 6, 7 and 8, any air-impermeable insulation shall be a Class II vapor retarder, or shall have a Class II vapor retarder coating or covering in direct contact with the underside of the insulation.
5. Insulation shall comply with Item 5.3 and either Item 5.1 or 5.2:
   5.1. Item 5.1.1, 5.1.2, 5.1.3 or 5.1.4 shall be met, depending on the air permeability of the insulation directly under the structural roof sheathing.
   5.1.1. Where only air-impermeable insulation is provided, it shall be applied in direct contact with the underside of the structural roof sheathing.
   5.1.2. Where air-permeable insulation is installed directly below the structural sheathing, rigid board or sheet insulation shall be installed directly above the structural roof sheathing in accordance with the \(R\)-values in Table R806.5 for condensation control.
   5.1.3. Where both air-impermeable and air-permeable insulation are provided, the air-impermeable insulation shall be applied in direct contact with the underside of the structural roof sheathing in accordance with Item 5.1.1 and shall be in accordance with the \(R\)-values in Table R806.5 for condensation control. The air-permeable insulation shall be installed directly under the air-impermeable insulation.
5.1.4. Alternatively, sufficient rigid board or sheet insulation shall be installed directly above the structural roof sheathing to maintain the monthly average temperature of the underside of the structural roof sheathing above 45°F (7°C). For calculation purposes, an interior air temperature of 68°F (20°C) is assumed and the exterior air temperature is assumed to be the monthly average outside air temperature of the three coldest months.

5.2. In Climate Zones 1, 2 and 3, air-permeable insulation installed in unvented attics shall meet the following requirements:

5.2.1. An approved vapor diffusion port shall be installed not more than 12 inches (305 mm) from the highest point of the roof, measured vertically from the highest point of the roof to the lower edge of the port.

5.2.2. The port area shall be greater than or equal to 1:600 of the ceiling area. Where there are multiple ports in the attic, the sum of the port areas shall be greater than or equal to the area requirement.

5.2.3. The vapor-permeable membrane in the vapor diffusion port shall have a vapor permeance rating of greater than or equal to 20 perms when tested in accordance with Procedure A of ASTM E96.

5.2.4. The vapor diffusion port shall serve as an air barrier between the attic and the exterior of the building.

5.2.5. The vapor diffusion port shall protect the attic against the entrance of rain and snow.

5.2.6. Framing members and blocking shall not block the free flow of water vapor to the port. Not less than a 2-inch (51 mm) space shall be provided between any blocking and the roof sheathing. Air-permeable insulation shall be permitted within that space.

5.2.7. The roof slope shall be greater than or equal to 3:12 (vertical/horizontal).

5.2.8. Where only air-permeable insulation is used, it shall be installed directly below the structural roof sheathing, on top of the attic floor, or on top of the ceiling.

5.2.9. Air-impermeable insulation, if any, where used in conjunction with air-permeable insulation, shall be directly above or below the structural roof sheathing and is not required to meet the $R$-value in Table 806.5. Where directly below the structural roof sheathing, there shall be no space between the air-impermeable insulation and air-permeable insulation.

5.2.10. Where air-permeable insulation is used and is installed directly below the roof structural sheathing, air shall be supplied at a flow rate greater than or equal to 50 CFM (23.6 L/s) per 1,000 square feet (93 m²) of ceiling. The air shall be supplied from ductwork providing supply air to the occupiable space when the conditioning system is operating. Alternatively, the air shall be supplied by a supply fan when the conditioning system is operating.

Exceptions:

1. Where both air-impermeable and air-permeable insulation are used, and the $R$-value in Table 806.5 is met, air supply to the attic is not required.

2. Where only air-permeable insulation is used and is installed on top of the attic floor, or on top of the ceiling, air supply to the attic is not required.

5.3. Where preformed insulation board is used as the air-impermeable insulation layer, it shall be sealed at the perimeter of each individual sheet interior surface to form a continuous layer.

Reason: Objective: Provide consistency with IBC and provide additional options
This code change provides consistency with the IBC and provides additional options. The building science related to this change can be found in the following link:

**Cost Impact:** The code change proposal will decrease the cost of construction
For some types of insulation and construction this will be a lower cost option.
2018 International Residential Code

R807.1 Attic access. Buildings with combustible ceiling or roof construction shall have an attic access opening to attic areas that have a vertical height of 30 inches (762 mm) or greater over an area of not less than 30 square feet (2.8 m²). The vertical height shall be measured from the top of the ceiling framing members to the underside of the roof framing members. The rough-framed opening shall be not less than 22 inches by 30 inches (559 mm by 762 mm) and shall be located in a hallway or other location with ready access. Where located in a wall, the opening shall be not less than 22 inches wide by 30 inches high (559 mm wide by 762 mm high). Where the access is located in a ceiling, minimum unobstructed headroom in the attic space shall be 30 inches (762 mm) at some point above the access measured vertically from the bottom of ceiling framing members. See Section M1305.1.3 for access requirements where mechanical equipment is located in attics.

Add new text as follows:

807.1.1 Attic access platform. A standing platform having an area not less than 32 square foot (2.98 m²) shall be constructed adjacent to the attic access opening. The platform shall be constructed of plywood or oriented stand board (OSB) sheathing of 5/8-inch (16 mm) minimum thickness and fastened to the ceiling joists or bottom truss chord with nails or screws, and elevated to create a nominal 10 inch (254 mm) deep cavity space for installing insulation beneath the sheathing. Framing materials shall be provided to support the platform sheathing.

Reason: The attic access opening is usually accessed by use of a ladder or similar device to gain entry into the attic space. Once inside the attic, there is little to no place to stand or maneuver once in the attic space. It is a life-safety issue everyday a person enters the attic regarding the location and placement of their feet once inside the attic. Some attics have limited insulation and the bottom chords of trusses or ceiling joists can be easily seen, however with the advent of blown-in insulation and added energy conservation measures the attic ceiling joists disappear below the insulation surface. This lack of a "platform" could lead to persons stepping onto the ceiling gypsum board and potentially falling between or through the attic joists/rafters, resulting in serious injury from a fall to the floor level below. A building occupant, owner, tenant, or repairman could sustain serious injury from a fall especially in an unlighted attic space. A second code change to add an electrical outlet receptacle has been proposed to IRC Sec. E3901.9 to provide a light source and power source during the performance of work or maintenance within an attic space.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The cost impact of adding this 32-sqft "platform" adjacent to the attic access opening is negligible to less than $100.00.
RB270-19
IRC®: R902.2

Proponent: Marcelo Hirschler, representing GBH International (mmh@gbhint.com)

2018 International Residential Code

Revise as follows:

R902.2 Fire-retardant-treated shingles and shakes. Fire-retardant-treated wood shakes and shingles shall be treated by impregnation with chemicals by the full cell vacuum-pressure process, in accordance with AWPA E1—a pressure process or other means during manufacture. The fire-retardant-treated wood shakes and shingles shall be tested in accordance with and produce the results required in Section R802.1.5. Each bundle shall be marked to identify the manufactured unit and the manufacturer, and shall be labeled to identify the classification of the material in accordance with the testing required in Section R902.1, the treating company and the quality control agency.

Reason: Section 802.1.5 explains that fire retardant treated wood needs to be manufactured by impregnation "with chemicals by a pressure process or other means during manufacture" and this section should state the same and not address a specific manufacturing process. The same words are also in the IBC and in the IWUIC. The added sentence ensures that the fire retardant treated wood products meet the requirements for fire-retardant treated wood products, now in chapter 8.

The other change being introduced is the elimination of AWPA C1, which is a standard that has been withdrawn by AWPA (since being issued in 2003). Moreover, AWPA C1 (entitled "All Timber Products - Preservative Treatment by Pressure Processes") does not address impregnation with fire retardant chemicals for improved flame spread but addresses preservative treatment.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is clarification since the requirements for fire retardant treated wood are already in the IRC code.

Proposal # 4824
**2018 International Residential Code**

Revise as follows:

**R902.4 Rooftop-mounted photovoltaic panel systems.** Rooftop-mounted *photovoltaic panel systems* installed on or above the roof covering shall be tested, listed and identified with a fire classification in accordance with UL 1703 and UL 2703. Class A, B or C *photovoltaic panel systems* and modules shall be installed in jurisdictions designated by law as requiring their use or where the edge of the roof is less than 3 feet (914 mm) from a lot line.

**Reason:** This correlates with the action taken in Group A for Section 1505.9 of the IBC, Proposal FS152-18. Fire classification for rooftop rack-mounted photovoltaic panel systems are determined in accordance with UL 2703. UL 1703 includes partial fire testing of the photovoltaic panel, which is one of the components of the photovoltaic panel system. UL 2703 uses the results of that component testing, and includes further evaluation and testing of the photovoltaic panel system (i.e. the photovoltaic panel and the rack support system) to establish the Fire Classification for the system. UL 1703 is referenced within UL 2703.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. Fire classification of these systems are determined in accordance with UL 2703 currently.

Proposal # 4266

---

**Proponent:** Jonathan Roberts, UL LLC, representing UL LLC (jonathan.roberts@ul.com)
SECTION R904
WIND REQUIREMENTS FOR ROOF COVERINGS

R904.1 Wind resistance for roof coverings. Roof coverings shall comply with the wind provisions and limitations of this section.

Revise as follows:

R904.1.1 Wind resistance of asphalt shingles. Asphalt shingles shall be tested in accordance with ASTM D7158. Asphalt shingles shall meet the classification requirements of Table R905.2.4.1-R904.1.1 for the appropriate ultimate design wind speed. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D7158 and the required classification in Table R905.2.4.1-R904.1.1.

Exception: Asphalt shingles not included in the scope of ASTM D7158 shall be tested and labeled in accordance with ASTM D3161. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D3161 and the required classification in Table R905.2.4.1-R904.1.1.

For SI: 1 foot = 304.8 mm; 1 mile per hour = 0.447 m/s.

a. The standard calculations contained in ASTM D7158 assume Exposure Category B or C and a building height of 60 feet or less. Additional calculations are required for conditions outside of these assumptions.
R904.1.2 **Concrete and clay tile.** In regions where wind design is required in accordance with Figure R301.2(5)B, wind loads on concrete and clay tile shall be determined in accordance with Section 1609.5 of the *International Building Code*. Concrete and clay tile shall be tested to determine their resistance to overturning due to wind loads in accordance with SBCCI SSTD 11 or ASTM C1568. Where concrete and clay roof tiles do not satisfy the limitations in Chapter 16 of the *International Building Code* for rigid tile, a wind tunnel test shall be used to determine the wind characteristics of the concrete or clay tile roof covering in accordance with SBCCI SSTD 11.

In regions where wind design is not required in accordance with Figure R301.2(5)B, concrete and clay tiles shall be attached in accordance with this section or Section R905.3.

R904.1.3 **Metal roof shingles.** Metal roof shingles shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3). Metal roof shingles shall be tested in accordance with FM 4474, UL 580 or UL 1897.

R904.1.4 **Mineral-surfaced roll roofing.** Mineral-surfaced roll roofing shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

R904.1.5 **Slate shingles.** Slate shingles shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

R904.1.6 **Wood shingles.** In regions where wind design is required in accordance with Figure R301.2(5)B, wood shingles shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3). In regions where wind design is not required in accordance with Figure R301.2(5)B, wood shingles are permitted to be attached in accordance with Section R905.7.

R904.1.7 **Wood shakes.** In regions where wind design is required in accordance with Figure R301.2(5)B, wood shakes shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3). In regions where wind design is not required in accordance with Figure R301.2(5)B, wood shakes are permitted to be attached in accordance with Section R905.8.

R904.1.8 **Metal roof panels.** Metal roof panels shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3). Metal roof panels shall be tested for wind resistance in accordance with FM 4474, UL 580, or UL 1897.

R904.1.9 **Photovoltaic shingles.** Photovoltaic shingles shall be tested in accordance with procedures and acceptance criteria in ASTM D 3161. Photovoltaic shingles shall comply with the classification requirements of Table R904.1.1 for the appropriate maximum basic wind speed. Photovoltaic shingle packaging shall bear a label to indicate compliance with the procedures in ASTM D 3161 and the required classification from Table R904.1.1.

R904.1.10 **Building-integrated Photovoltaic roof panels.** *BIPV roof panels* shall be tested in accordance with UL 1897. *BIPV roof panel* packaging shall bear a label to indicate compliance with UL 1897.

R904.1.11 **Other roof systems.** Built-up, modified bitumen, fully adhered or mechanically attached single ply systems, sprayed polyurethane foam, and liquid applied roof coverings shall be tested in accordance with FM 4474, UL1897 or UL 580 and installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).
Revise as follows:

**R905.1 Roof covering application.** Roof coverings shall be applied in accordance with the applicable provisions of this section and the manufacturer’s installation instructions. **Unless otherwise specified in this section, roof coverings shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3), comply with the wind requirements specified in Section R904.**

**R905.16.6 Wind resistance.** Photovoltaic- **Wind resistance of photovoltaic shingles** shall be tested in accordance with procedures and acceptance criteria in ASTM D3161. Photovoltaic shingles shall comply with the classification requirements of Table R905.2.4.1 for the appropriate maximum basic wind speed. Photovoltaic shingle packaging shall bear a label to indicate compliance with the procedures in ASTM D3161 and the required classification from Table R905.2.4.1. Section R904.

**R905.17.7 Wind resistance.** Wind resistance of BIPV roof panels shall be tested in accordance with UL 1897. BIPV roof panel packaging shall bear a label to indicate compliance with UL 1897. Section R904.

Add new standard(s) as follows:

**ASTM**

(Mechanical Uplift Resistance Method) R904.1.2

**FM**

4474-2011: American National Standard for Evaluating the Simulated Wind Uplift Resistance of Roof Assemblies Using Static Positive and/or Negative Differential Pressures R904.1.3, R904.1.8

**ICC**

SBCCI SSTD 11-97: Test Standard for Determining Wind Resistance of Concrete or Clay Roof Tiles R904.1.2

**UL**

580-2006: Test for Uplift Resistance of Roof Assemblies-with Revisions through October 2013 R904.1.3, R904.1.8

**Reason:** This proposal is one of two proposals intended to clarify the wind limitations in the IRC. Section R301.2.1.1 intends to limit the applicability of the IRC to areas where wind design is not required in accordance with Figure R301.2(5)B. However, Chapter 9 contains high wind requirements for asphalt shingles and for underlayment in wind design required regions, but for no other roof coverings. While Section R905.1 states that unless otherwise specified, roof coverings have to resist the component and cladding loads specified in Table...
R302(2), that requirement is not necessarily correct for all roof coverings. Prescriptive attachment methods are provided for concrete and clay tile but the code does not specify any wind limitations on the use of this prescriptive method.

Therefore, a new section is proposed for Chapter 9 on roof coverings that specifically addresses the wind limitations in the IRC for roof covering attachment and specifies the performance requirements for roof coverings in wind design required regions. It is similar to and was patterned after Section 1504 in the IBC.

This proposal is not intended to change any technical requirements in the IRC related to wind design. It is intended to simply clarify the wind requirements for roof coverings in the IRC.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
This code change proposal will not increase the cost of construction as it is primarily a clarification.

**Staff Analysis:** The referenced standard, ASTM C1568-08(2013), FM 4474-2011, ICC SBCCI SSTD 11-97 and UL 580-2006 are currently referenced in other 2018 I-codes.
R905.1.1 Underlayment. Underlayment for asphalt shingles, clay and concrete tile, metal roof shingles, mineral-surfaced roll roofing, slate and slate-type shingles, wood shingles, wood shakes, metal roof panels and photovoltaic shingles shall conform to the applicable standards listed in this chapter. Underlayment materials required to comply with ASTM D226, D1970, D4869, and D6757 and ASTM WK51913 shall bear a label indicating compliance to the standard designation and, if applicable, type classification indicated in Table R905.1.1(1). Underlayment shall be applied in accordance with Table R905.1.1(2). Underlayment shall be attached in accordance with Table R905.1.1(3).

Exceptions:

1. As an alternative, self-adhering polymer-modified bitumen underlayment complying with ASTM D1970 installed in accordance with both the underlayment manufacturer’s and roof covering manufacturer’s instructions for the deck material, roof ventilation configuration and climate exposure for the roof covering to be installed, shall be permitted.

2. As an alternative, a minimum 4-inch-wide (102 mm) strip of self-adhering polymer-modified bitumen membrane complying with ASTM D1970, installed in accordance with the manufacturer’s installation instructions for the deck material, shall be applied over all joints in the roof decking. An approved underlayment for the applicable roof covering for maximum ultimate design wind speeds, $V_{ult}$, less than 140 miles per hour shall be applied over the entire roof over the 4-inch-wide (102 mm) membrane strips.

3. As an alternative, two layers of underlayment complying with ASTM D226 Type II; or ASTM D4869 Type III or Type IV; or ASTM WK51913 shall be permitted to be installed as follows in 3.1 through 3.4:

   3.1. Apply a 19-inch-wide (483 mm) strip of underlayment parallel with the eave. Starting at the eave, apply 36-inch-wide (914 mm) strips of underlayment felt, overlapping successive sheets 19 inches (483 mm). End laps shall be 4 inches (102 mm) and shall be offset by 6 feet (1829 mm).

   3.2. The underlayment shall be attached with corrosion-resistant fasteners in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at side and end laps.

   3.3. Underlayment shall be attached using metal or plastic cap nails with a nominal cap diameter of not less than 1 inch (25 mm). Metal caps shall have a thickness of not less than 32-gage sheet metal. Power-driven metal caps shall have a thickness of not less than 0.010 inch (0.25 mm). Minimum thickness of the outside edge of plastic caps shall be 0.035 inch (0.89 mm).

   3.4. The cap nail shank shall be not less than 0.083 inch (2.11 mm) for ring shank cap nails and 0.091 inch (2.31 mm) for smooth shank cap nails. Cap nail shank shall have a length sufficient to penetrate through the roof sheathing or not less than $\frac{3}{4}$ inch (19 mm) into the roof sheathing.

Add new text as follows:
ASTM WK51913 - ????: New Specification for Mechanically Attached Polymeric Roof Underlayment Used in Steep Slope Roofing

Reason: This is a placeholder for the ASTM Work Item to develop a standard related to synthetic underlayments. This will be the first ASTM Standard that applies specifically to synthetic underlayments and includes requirements that are related directly to synthetic underlayments. These requirements are much more appropriate for synthetic underlayment products than testing in accordance with the current standards which are specifically for asphalt impregnated products.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This proposal simply adds requirements for products that are already in widespread use.

Staff Analysis: A review of the standard proposed for inclusion in the code, ASTM WK51913, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Residential Code

Revise as follows:

R905.1.1 Underlayment. Underlayment for asphalt shingles, clay and concrete tile, metal roof shingles, mineral-surfaced roll roofing, slate and slate-type shingles, wood shingles, wood shakes, metal roof panels and photovoltaic shingles shall conform to the applicable standards listed in this chapter. Underlayment materials required to comply with ASTM D226, D1970, D4869 and D6757 shall bear a label indicating compliance to the standard designation and, if applicable, type classification indicated in Table R905.1.1(1). Underlayment shall be applied in accordance with Table R905.1.1(2). Underlayment shall be attached in accordance with Table R905.1.1(3).

Exceptions:

1. As an alternative, self-adhering polymer-modified bitumen underlayment complying with ASTM D1970 installed in accordance with both the underlayment manufacturer’s and roof covering manufacturer’s instructions for the deck material, roof ventilation configuration and climate exposure for the roof covering to be installed, shall be permitted.

2. As an alternative, a minimum 4-inch-wide (102 mm) strip of self-adhering polymer-modified bitumen membrane complying with ASTM D1970, installed in accordance with the manufacturer’s installation instructions for the deck material, shall be applied over all joints in the roof decking. An approved underlayment for the applicable roof covering for maximum ultimate design wind speeds, \( V_{uk} \), less than 140 miles per hour shall be applied over the entire roof over the 4-inch-wide (102 mm) membrane strips.

3. As an alternative, two layers of underlayment complying with ASTM D226 Type II or ASTM D4869 Type III or Type IV shall be permitted to be installed as follows in 3.1–3.4:

   3.1. Apply a 19-inch-wide (483 mm) strip of underlayment parallel with the eave. Starting at the eave, apply 36-inch-wide (914 mm) strips of underlayment felt, overlapping successive sheets 19 inches (483 mm). End laps shall be 4 inches (102 mm) and shall be offset by 6 feet (1829 mm).

   3.2. The underlayment shall be attached with corrosion-resistant fasteners in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at side and end laps.

   3.3. Underlayment shall be attached using metal or plastic cap nails with a nominal cap diameter of not less than 1 inch (25 mm). Metal caps shall have a thickness of not less than 32-gage sheet metal. Power-driven metal caps shall have a thickness of not less than 0.010 inch (0.25 mm). Minimum thickness of the outside edge of plastic caps shall be 0.035 inch (0.89 mm).

   3.4. The cap nail shank shall be not less than 0.083 inch (2.11 mm) for ring shank cap nails and 0.091 inch (2.31 mm) for smooth shank cap nails. Cap nail shank shall have a length sufficient to penetrate through the roof sheathing or not less than 3/4 inch (19 mm) into the roof sheathing.

---

**TABLE R905.1.1(1)**

**UNDERLAYERMENT TYPES**
Portions of table not shown remain unchanged.

<table>
<thead>
<tr>
<th>ROOF COVERING</th>
<th>SECTION</th>
<th>MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} &lt; 140$ MPH</th>
<th>MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} \geq 140$ MPH</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asphalt shingles</td>
<td>R905.2</td>
<td>ASTM D226 Type I or Type II ASTM D4869 Type I, II, III or IV ASTM D6757</td>
<td>ASTM D226 Type II ASTM D4869 Type III or Type IV ASTM D6757</td>
</tr>
</tbody>
</table>

For SI: 1 mile per hour = 0.447 m/s.

**Reason:** The proposal makes two editorial changes. The alternate for ASTM D 1970 is redundant as that standard is listed in Section R905.1.1. Table R905.1.1 (1) includes ASTM D226 Type II for high wind areas; that material is also appropriate for lower wind zone areas.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

The proposal is editorial.

Proposal # 5672

(testafford@charter.net)

2018 International Residential Code

Revise as follows:

R905.1.1 Underlayment. Underlayment for asphalt shingles, clay and concrete tile, metal roof shingles, mineral-surfaced roll roofing, slate and slate-type shingles, wood shingles, wood shakes, metal roof panels and photovoltaic shingles shall conform to the applicable standards listed in this chapter. Underlayment materials required to comply with ASTM D226, D1970, D4869 and D6757 shall bear a label indicating compliance to the standard designation and, if applicable, type classification indicated in Table R905.1.1(1). Underlayment shall be applied in accordance with Table R905.1.1(2). Underlayment shall be attached in accordance with Table R905.1.1(3).

Exceptions:

1. As an alternative, self-adhering polymer-modified bitumen underlayment complying with ASTM D1970 installed in accordance with both the underlayment manufacturer’s and roof covering manufacturer’s instructions for the deck material, roof ventilation configuration and climate exposure for the roof covering to be installed, shall be permitted.

2. As an alternative, a minimum 4-inch-wide (102 mm) strip of self-adhering polymer-modified bitumen membrane complying with ASTM D1970, installed in accordance with the manufacturer’s installation instructions for the deck material, shall be applied over all joints in the roof decking. An approved underlayment for the applicable roof covering for maximum ultimate design wind speeds, $V_{\text{ult}}$, less than 140 miles per hour areas where wind design is not required in accordance with Figure R301.2(4)B shall be applied over the entire roof over the 4-inch-wide (102 mm) membrane strips.

3. As an alternative, two layers of underlayment complying with ASTM D226 Type II or ASTM D4869 Type III or Type IV shall be permitted to be installed as follows in 3.1–3.4:

   3.1. Apply a 19-inch-wide (483 mm) strip of underlayment parallel with the eave. Starting at the eave, apply 36-inch-wide (914 mm) strips of underlayment felt, overlapping successive sheets 19 inches (483 mm). End laps shall be 4 inches (102 mm) and shall be offset by 6 feet (1829 mm).

   3.2. The underlayment shall be attached with corrosion-resistant fasteners in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at side and end laps.

   3.3. Underlayment shall be attached using metal or plastic cap nails with a nominal cap diameter of not less than 1 inch (25 mm). Metal caps shall have a thickness of not less than 32-gage sheet metal. Power-driven metal caps shall have a thickness of not less than 0.010 inch (0.25 mm). Minimum thickness of the outside edge of plastic caps shall be 0.035 inch (0.89 mm).

   3.4. The cap nail shank shall be not less than 0.083 inch (2.11 mm) for ring shank cap nails and 0.091 inch (2.31 mm) for smooth shank cap nails. Cap nail shank shall have a length sufficient to penetrate through the roof sheathing or not less than $\frac{3}{4}$ inch (19 mm) into the roof sheathing.

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s.

**Reason:** This code change simply requires an extra layer of 30# roofing felt (ASTM D 226 Type II, or ASTM D 4869 Types III or IV) for areas vulnerable to roof covering loss and subsequent water intrusion in the hurricane-prone regions. The fastening of the underlayment remains the same as required in the 2018 IRC except the use of staples as a fastening method has been removed. The effectiveness of staples in keeping the underlayment in place when subjected to hurricane-level wind loads has not been tested. Additionally, the trigger for the enhanced underlayment has been changed to where wind design is required in accordance with Figure.
The wind design required trigger is consistent with other limitations in the IRC and would also capture areas impacted by Hurricane Michael where design wind speeds currently range from 130 mph to 140 mph. However, for the northeastern U.S. and Alaska, where the wind design required region is based on the 140 mph wind speed contour, the trigger remains the same. This proposal would also remove the enhanced underlayment requirements from the Special Wind Regions.

Water infiltration due to wind driven rain has been well documented from post-hurricane damage assessments where hurricane winds were strong enough to blow off the primary roof covering, but not strong enough to blow off roof sheathing. In such instances, significant property damage and extended occupant displacement routinely occur due to water intrusion. In many cases, the building will appear relatively undamaged from the exterior except for roof covering loss. However, a closer inspection would reveal significant interior and contents damage.

Water entry can occur where it is able to infiltrate through the roof, walls, vents, windows, and/or doors, or at interfaces between these items. Water intrusion can cause extensive damage to interior finishes, furnishings, and other contents, and can lead to ceiling collapse when attic insulation is saturated. When power is lost and/or a building cannot otherwise be dried out within 24–48 hours, additional issues such as mold can develop, potentially extending the period during which the property may not be available for use. An insurance closed claims study for residential properties conducted following Hurricane Charley in 2004 indicated interior losses and additional living expenses were 27% of the total loss costs.

Recent hurricanes have not been an exception. The following photographs show buildings damaged due to Hurricane Michael which impacted Mexico Beach and the Panama City area of Florida (other areas as well). While structurally, the buildings performed well, each had extensive interior damage likely due to wind driven rain and roof covering loss. Also, parts of North Carolina that were hit by Hurricane Florence in 2018 are in areas where the design wind speed is around 145 mph. However, these areas suffered substantial residential roof damage at winds which measured only at around 100 mph.

Tests performed by IBHS at the Research Center have consistently shown that the secondary roof underlayment strategies recommended by the IBHS Fortified Home™ - Hurricane program consistently show significantly reduced water intrusion rates when one of these strategies was employed. Two of these strategies are already recognized by the code in Exceptions 1 and 2 to Section R905.1.1. A 2011 hurricane demonstration clearly showed the benefit of sealing the seams of the roof deck sheathing which is one of the strategies recognized in Exception 2 to Section R905.1.1.

A summary of the results of the demonstration can be viewed at the following link: http://ibhstest.wpengine.com/ibhs-news-releases/ibhs-hurricane-demonstration-illustrates-importance-of-sealed-roof-deck-3/.

The wind driven rain demonstration can be viewed at the following link: https://disastersafety.org/thunderstorms/wind-driven-rain-demo/.

A more recent study included an assessment of a new approach where the roof is covered with two layers of high-quality underlayment attached with cap nails. Based on the performance achieved with this system, it has now been added to the FORTIFIED Home—Hurricane program as a fifth option for achieving a sealed roof deck. This report is identified in the bibliography and has been included as an attachment to this code change. All of the mitigation strategies, including the two layers of felt underlayment reduced water entry into the attic space by 70% or more.
Bibliography: Brown, T.M., Quarles, S.L., Giammanco, I.M., Brown, R., Insurance Institute for Business and Home Safety, "Building Vulnerability to Wind-Driven Rain Entry and Effectiveness of Mitigation Techniques." 14th International Conference on Wind Engineering (ICWE).

Cost Impact: The code change proposal will increase the cost of construction
If one of the methods in Exceptions 1 or 2 of Section R905.1.1 are used, this proposal will not increase the cost of construction.

If the double layer of underlayment option is used, for areas where wind design is required, the cost of the additional layer of underlayment will vary by region. However, for a 2000 square foot roof, the cost increase for the additional layer of underlayment will be between $100 to $200. For areas where the design wind speed is less than 140 mph but equal to or greater than 130 mph in the wind design required region, additional fasteners will be required in addition to the additional layer of underlayment.

**Add new text as follows:**

**ASTM**

**ASTM WK51913 - ?????: New Specification for Mechanically Attached Polymeric Roof Underlayment Used in Steep Slope Roofing**

**Reason:** This proposal references an ASTM Work Item for a new ASTM Standard that will apply exclusively to synthetic underlayments. The proposal simply stipulates new performance requirements for products that are already in widespread use.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction.

This proposal references a proposed ASTM Standard that will, for the first time, apply specific performance requirements to synthetic underlayment products that are already in widespread use and will therefore not affect the cost of construction.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ASTM WK51913-????, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

---

Proposal # 5319

**ICC COMMITTEE ACTION HEARINGS :::: April, 2019**

RB276-19

**RB679**
2018 International Residential Code

Revise as follows:

**R905.3.1 Deck requirements.** Concrete and clay tile shall be installed only over solid sheathing or spaced structural sheathing boards.

**Reason:** This section is amended to require concrete and clay tiles to be installed only over solid structural sheathing boards. The change is necessary because there were numerous observations of tile roofs pulling away from wood framed buildings following the 1994 Northridge Earthquake. The SEAOSC/LA City Post Northridge Earthquake committee findings indicated significant problems with tile roofs was due to inadequate design and/or construction. Therefore, the amendment is needed to minimize such occurrences in the event of future significant earthquakes. This amendment will reduce the failure of concrete and clay tile roofs during a significant earthquake and is in accordance with the scope and objectives of the Internation Building Code.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposal limits the "spaces sheathing", therefore it does not increase any cost.
RB278-19
IRC®: R905.3.6 (New)

Proponent: Rick Allen, International Staple, Nail and Tool Association, representing International Staple, Nail and Tool Association (rallen@isanta.org)

2018 International Residential Code
Revise as follows:

R905.3.6 Fasteners. Nails shall be corrosion resistant and not less than 11-gage, [0.120 inch (3 mm)] 5/16-inch (11 mm) head, and of sufficient length to penetrate the deck not less than 3/4 inch (19 mm) or through the thickness of the deck, whichever is less. Attaching wire for clay or concrete tile shall not be smaller than 0.083 inch (2 mm). Perimeter fastening areas include three tile courses but not less than 36 inches (914 mm) from either side of hips or ridges and edges of eaves and gable rakes.

Reason: ASTM F1667-18 requires that when gage is used as a diameter for nails, a decimal equivalent must also be shown. This requirement was put in place because of the multiple and conflicting wire gage tables that are used in the manufacturing of nails.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This proposal will not change the cost of production. It only provides clarification required by ASTM F01667-18

Proposal # 4085
2018 International Residential Code

Add new text as follows:

R905.4.4.1 Wind Resistance of metal roof shingles. Metal roof shingles applied to a solid or closely fitted deck shall be tested in accordance with ASTM D3161, FM 4474, UL 580, or UL 1897. Metal roof shingles tested in accordance with ASTM D3161 shall meet the classification requirements of Table R905.4.4.1 for the appropriate maximum basic wind speed and the metal shingle packaging shall bear a label to indicate compliance with ASTM D3161 and the required classification in Table R905.2.4.1

For SI: 1 foot = 304.8 mm; 1 mile per hour = 0.447 m/s.

a. The standard calculations contained in ASTM D7158 assume Exposure Category B or C and a building height of 60 feet or less. Additional calculations are required for conditions outside of these assumptions.

Revise as follows:

R301.2.1 Wind design criteria. Buildings and portions thereof shall be constructed in accordance with the wind provisions of this code using the ultimate design wind speed in Table R301.2(1) as determined from Figure R301.2(5)A. The structural provisions of this code for wind loads are not permitted where wind design is required as specified in Section R301.2.1.1. Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where not otherwise specified, the wind loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.4. Metal roof shingles shall be designed for wind...
speeds in accordance with Section R905.4.4. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 from the roof assembly to the foundation.

Add new text as follows:

580—2006: Test for Uplift Resistance of Roof Assemblies—with Revisions through October 2013

Reason: This proposal recognizes wind resistance of "metal roof shingles" as a separate item in Section R905.4.4.1. This product is not the same in all respects as asphalt shingles (Section R905.2.4.1) which is the reason for addition of this section.

Table R905.2.4.1 is appropriate to metal roof shingles. The title is changed to reflect modifications that were made to ASTM D3161 dating back to 2013.

The major issue is that the wind uplift testing is currently addressed by multiple standards that determine compliance through uplift ratings. Metal shingle performance is not correctly represented by these current tests due to the air permeability inherent in the design of the shingle units, so a fan-induced method was developed through ASTM, with UL as a major proponent, as an alternative to the required uplift resistance testing. Manufacturers use one or more of the standards listed to determine this performance and feel they should choose the correct and most representative method to show compliance.

ASTM D3161 (Fan Induced) was originally created for asphalt shingles however the standard was expanded in 2013 to evaluate wind resistance of discontinuous, air permeable, steep slope roofing products with or without contribution from adhesives or mechanical interlocking to hold down the leading tab edge and is not limited to asphalt shingles. This clearly includes metal shingles (specifically identified in Scope Section 1.3).

ASTM D3161 removes difficulties for metal shingle manufacturers currently required to run UL 1897 or UL 580 in a non-air-permeable manner that does not fairly represent the product. UL has provided metal shingle wind classifications for many years and currently has D3161-related listings in the Online Classification Directory. UL was also a proponent of the D3161 scope change showing acceptance of D3161 as a means to demonstrate metal shingle wind resistance. The scope is clear. "This test method was formerly titled "Wind Resistance of Asphalt Shingles (Fan-Induced Method)" but was revised to acknowledge that the method is applicable to many other steep slope roofing products and has been used to evaluate the wind resistance of those products for many years by several testing and certification laboratories."

The modification to Section R301.2.1 is placed to point the reader to Section R905.4.4.1.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This proposal introduces alternate wind resistance testing that is more appropriate to metal shingles.

Staff Analysis: The referenced standard, FM 4474-2011 and UL 580-2006/13, is currently referenced in other 2018 I-codes.
2018 International Residential Code

Revise as follows:

R905.7.1 Deck requirements. Wood shingles shall be installed on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall be not less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners. Spaced sheathing shall be open to the building interior and shall not be backed with spray foam or other moisture impermeable material.

Reason: Moisture is driven into the shingles by the heating of the sun. When the back or interior side of the shingles are open to air the moisture and heat has two ways to escape the shingle, toward the inside and toward the outdoors. When foam insulation is added to the back side of the shingles, there is only one escape path. The foam also stops heat transfer and builds up the temperature of the shingle, resulting in more rapid deterioration from both moisture and heat.

Bibliography: Fisette, P. Housewraps, Felt Paper and Weather Penetration Barriers: Building Materials and Wood Technology, University of Massachusetts Amherst, 2001

Cost Impact: The code change proposal will not increase or decrease the cost of construction

This change is primarily to stop a practice that often occurs as a retrofit. It is not a normal part of any construction process or system, but can sometimes be added to a building interior during modifications. No costs are involved when following standard construction practices.
RB281-19
RPC®: R905.8.1

Proponent: David Roodvoets (davelee@ix.netcom.com)

2018 International Residential Code

Revise as follows:

R905.8.1 Deck requirements. Wood shakes shall be used only on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall be not less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners. Where 1-inch by 4-inch (25 mm by 102 mm) spaced sheathing is installed at 10 inches (254 mm) on center, additional 1-inch by 4-inch (25 mm by 102 mm) boards shall be installed between the sheathing boards. Spaced sheathing shall not be backed with spray foam or other moisture impermeable material.

Reason: Moisture is driven into the shakes by the heating of the sun. When the back or interior side of the shakes are open to air the moisture has two ways to escape the shake, toward the inside and toward the outdoors. When foam insulation is added to the back side of the shakes there is only one escape path. The foam also stops heat transfer and builds up the temperature in the shake resulting in more rapid deterioration from both moisture and heat.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This change is primarily to stop a practice that often occurs as a retrofit. It is not a normal part of any construction process or system, but can sometimes be added to a building interior during modifications. No costs are involved when following standard construction practices.

Add new standard(s) as follows:

UL

UL 907-94: Fireplace Accessories - with revisions through November 2014

Reason: This proposal aligns the masonry fireplace requirements in the IRC with the masonry fireplace requirements in the IMC, Section 902.2.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.
This proposal only requires that if listed and labeled fireplace accessories are used, they shall be installed in accordance with the manufacturer’s installation instructions and be listed in accordance with UL 907.

Staff Analysis: The referenced standard, UL 907-94, is currently referenced in other 2018 I-codes.
2018 International Residential Code

Add new text as follows:

R101.2.1 Manufactured Home Installation. The installation of a new manufactured home shall be in accordance with HUD 24 CFR 3285 and the manufacturer's installation instructions.

Add new standard(s) as follows:

24 CFR 3285: Model Manufactured Home Installation Standards

Delete without substitution:

E MANUFACTURED HOUSING USED AS DWELLINGS

SECTION AJ101 PURPOSE AND INTENT

Add new text as follows:

AJ101.4 Relocated Manufactured Home A manufactured home that is being relocated to a new foundation system shall comply with one of the following standards:

1. The manufacturer's installation instructions for that specific model.
2. The latest installation instructions provided by the manufacturer of the manufactured home.
3. NFPA 225

AJ101.4.1 Repair, renovation, alteration and reconstruction of a manufactured home The repair, renovation, alteration and reconstruction of a manufactured home shall comply with Appendix J.

Revise as follows:

SECTION AJ701 REFERENCED STANDARDS ASTM
Reason: This proposal will delete all of Appendix E.
All manufactured home installations are required to conform to 24 CFR 3285 - Model Manufactured Home Installation Standards. In accordance with 24 CFR 3285.2, a manufacturer of manufactured homes must provide installation instructions. Federal standards regulate the installation of a manufactured home. This proposal directly references 24 CFR 3285 within the scope of the IRC for new installations and addresses the repair, renovation, relocation, renovation and addition of manufactured homes in Appendix J.

Cost Impact: The code change proposal will increase the cost of construction
The proposal will increase the cost of construction in places that Appendix E is less restrictive than 24 CFR 3285.

Staff Analysis: A review of the standard proposed for inclusion in the code, HUD 24 CFR CFR 3285 and NFPA 225-17, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
This proposal will delete the entirety of Appendix E.
2018 International Residential Code

Add new text as follows:

**AF103.7 Sidewall Vent Termination.** The vent pipe shall be permitted to be routed out the side of the building and terminated at the sidewall provided the requirements of this section are met.

**AF103.7.1 Vent Location.** The vent termination shall be located:
1. Not less than 3 feet (914 mm) above any forced-air inlet located within 10 feet (3048 mm).
2. Not less than 4 feet (1219 mm) below, 4 feet (1219 mm) horizontally from or 1 foot (305 mm) above any door, operable window or gravity air inlet into any building. The bottom of the vent terminal shall be located not less than 12 inches (305 mm) above finished ground level.
3. Not over public walkways or over an area where condensate or vapor could create a nuisance or hazard or could be detrimental to the operation of regulators, relief valves or other equipment.
4. Not less than 12 inches (305 mm) above finished ground level.

**AF103.7.2 Vent Pipe.** Vent pipe joints shall be solvent welded.

**AF103.7.3 Fan.** A radon fan shall be installed to activate the system and shall meet the following conditions:
1. The fan shall be a listed in-line fan designed for radon mitigation and be installed in accordance with NFPA 70 and the manufacturer’s installation instructions.
2. The fan shall be airtight and installed within 4 feet (1219 mm) from the point the vent passes through the wall.
3. The fan shall have ready access for repair or replacement.
4. The fan shall be connected to a system failure alarm.

**AF103.7.4 Testing.** The radon system shall be tested as follows:
1. Testing shall be performed after the dwelling passes its air tightness test and after the radon control system and HVAC installations are complete.
2. The radon fan and HVAC system shall be operating during the test.
3. Testing shall be performed with the windows closed.
4. Testing shall be performed with the exterior doors closed, except when being used for entrance or exit.
5. If the test result is 4 pCi/L or greater, then the system shall be modified and retested until the test result is less than 4 pCi/L.
6. The final test results shall be included with the construction documents.

Reason: The intent of this proposal is to allow sidewall venting of radon reduction systems without changing the other provisions of Appendix F. An active system is required if the sidewall venting option is chosen, but builders and owners still have the option of constructing a passive through-the-roof system. The sidewall termination option can provide advantages for those who have already decided to install a radon fan and want the benefits of simple vent routing or want to have better access to the fan for monitoring and maintenance. The side-vent option reduces ice formation on the roof vent. In cold climates ice forms on the roof vent as warm moist air meets cold outdoor air.
venting (Henschel, 1995) showed a negligible re-entrainment level of 0.07 pCi/L when a concentration of 25 times the EPA action level was being exhausted at grade level. At the action level of 4 pCi/L, the calculated re-entrainment level would be a negligible 0.003 pCi/L. This same research has been used as substantiation to allow sidewall radon vent termination in Canada (see Health Canada, Reducing Radon Levels in Existing Homes: A Canadian Guide for Professional Contractors). Recent additional testing summarized below supports this view.

The following is from Summary Report on Active Soil Depressurization (ASD) Field Study (Health Canada, 2016), emphasis added. The 200 Bq/m³ in the quoted text below is the Canadian action level for radon.

"The second part of the study investigated how quickly radon levels dissipate with distance away from the side-wall discharge point. To do this, real-time radon dispersion measurements were conducted at 5 homes. At each home, arrays of approximately 10-15 continuous radon monitors were set up at fixed heights and distances away from where the exhaust is expelled, and measurements were conducted for a continuous period of roughly 6 hours. Generally speaking, radon levels fell from thousands of Bq/m³ to less than the 200 Bq/m³ guideline value within 1-2 metres, indicating a rapid decrease with distance.

"The long-term indoor post-mitigation results indicate that radon levels can be successfully lowered, and maintained, to levels well below the Canadian guideline value using an ASD mitigation system with an indoor mounted fan and side-wall discharge. This further implies that indoor leakage of radon from the system, and re-entry of radon into the home from the exhaust stream, were not issues of concern for the systems tested. As predicted, extreme cold climatic conditions did not cause freeze-up issues or impact the function of the ASD fan or system, as system components were not directly exposed to harsh conditions in the way they may be with the traditional geometry. The alternative, and conveniently less expensive, ASD geometry has been shown to be quite viable."
A sidewall termination can also be beneficial in cold climates where water vapor can freeze at the termination of tall, uninsulated systems, closing off the vent.

"Condensation problems can be reduced if the exhaust is discharged from a short pipe near ground level at right angles to the wall, similar to the exhausts from fan powered combustion appliances. ... A major advantage in cold weather areas is that the exposed discharge pipe is short and horizontal, reducing condensation and frost problems." (Health Canada, Reducing Radon Levels in Existing Homes: A Canadian Guide for Professional Contractors).

When considering how big of an issue freezing can be, it's important to note that most of the Canadian population lives near the U.S. border in climate zone 6, which is the same climate zone that covers a significant portion of the northern U.S. This is demonstrated in the figure to the left which shows IECC climate zones extended into Canada. Coincidentally, the same region covers much of radon zone 1.

The proposed language for the vent termination clearances was taken from IRC Section G2427.8 where it applies to a mechanical draft venting system. The power source for a future fan is adequately addressed in AF103.12.

The Canadian - National Radon Proficiency Program (C-NRPP) also recognizes sidewall terminations for radon reduction systems and shows the following image on its website: [https://c-nrpp.ca/radonreduction/](https://c-nrpp.ca/radonreduction/). The C-NRPP was established in 2014 as an agreement between the Canadian Association of Radon Scientists and Technologists and Health Canada.

Cost Impact: The code change proposal will not increase or decrease the cost of construction Installing an active radon system with a sidewall termination is an option, and the passive, through-the-roof option is still available.

Proposal # 4478

RB286-19
2018 International Residential Code

Add new text as follows:

**AF103.13 Testing.** The building or dwelling unit shall be tested and verified as having an indoor radon level less than the USEPA Action level of 4 picocuries per liter (pCi/L). Testing shall be conducted in accordance with ANSI/AARST MAH. Where required by the code official testing shall be provided by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be conducted at any time after the completion of the building thermal envelope, with all doors and windows in place, and after the building heating and cooling systems are installed.

**AF103.14 Mitigation.** Where testing results indicate the radon level is 4 pCi/L or greater steps shall be taken to mitigate radon levels, including the installation of a radon fan in the anticipated location prescribed in Section AF103.12. Where required by the code official mitigation shall be provided by an approved third party. Testing as prescribed in Section AF103.13 shall be repeated until results are below 4 pCi/L.

**Reason:** This proposal updates Appendix F Radon Control Methods by adding new requirements for Radon Testing and Mitigation. Radon is an odorless, colorless radioactive that can only be detected through a radon test. Various inexpensive test methods are available. If the test results exceed the USEPA Action Level of 4 picocurries per liter (pCi/L) then the excess gas can be removed by adding a radon fan to the preliminary system properly installed per Appendix F. An active radon mitigation system can be up to 99% effective in removing radon gas from a home.

**Bibliography: Add Referenced Standards:**
AARST/ANSI MAH - Protocol For Conducting Measurements Of Radon And Radon Decay Products In Homes

**Cost Impact:** The code change proposal will increase the cost of construction.
Radon testing can cost between $20 and $125 depending on the type of test and who performs the test. Only if excess levels of radon are detected will a radon fan will need to be added which will increase the cost between $100 and $300.

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ANSI/AARST MAH, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 5515
2018 International Residential Code

SECTION AF101
SCOPE

Revise as follows:

AF101.1 General. This appendix contains requirements for radon control methods in new construction in jurisdictions where radon-resistant construction is required. Inclusion of this appendix by jurisdictions shall be determined through the use of locally available data or determination of Zone 1 designation in Figure AF101 and Table AF101(1).

Add new definition as follows:

SECTION AF102
DEFINITIONS

AF102.1 General. For the purpose of these requirements, the terms used shall be defined as follows:

Delete without substitution:

DRAIN TILE LOOP. A continuous length of drain tile or perforated pipe extending around all or part of the internal or external perimeter of a basement or crawl space footing.

Revise as follows:

RADON GAS. A naturally occurring, chemically inert, radioactive gas that is not detectable by human senses. As a gas, it can move readily through particles of soil and rock, and can accumulate under the slabs and foundations of homes where it can easily enter into the living space through construction cracks and openings. The element Rn, which is a radioactive colorless, odorless, tasteless, cancer-causing gas that occurs naturally as a decay product of radium.

Add new definition as follows:

RADON ROUGH-IN. The installation of all parts and materials of sub-membrane or sub-slab depressurization system including gas permeable layers, soil gas retarders, membranes, piping, connectors, terminations, and power sources.
SOIL-GAS-RETARDER. A continuous membrane of 6-mil (0.15 mm) polyethylene or other equivalent material used to retard the flow of soil gases into a building.

Revise as follows:

SUBMEMBRANE DEPRESSURIZATION SYSTEM. A system designed to achieve lower submembrane air pressure relative to crawl space air pressure by use of a fan-powered vent drawing air from beneath the soil-gas-retarder membrane.

SUBSLAB DEPRESSURIZATION SYSTEM (Active). A system designed to achieve lower subslab air pressure relative to indoor sub-slab air pressure by use of a fan-powered vent drawing air from beneath the slab.

Delete without substitution:

SUBSLAB DEPRESSURIZATION SYSTEM (Passive). A system designed to achieve lower subslab air pressure relative to indoor air pressure by use of a vent pipe routed through the conditioned space of a building and connecting the subslab area with outdoor air, thereby relying on the convective flow of air upward in the vent to draw air from beneath the slab.

SECTION AF103 REQUIREMENTS

Revise as follows:

AF103.1 General. The following construction techniques are intended to resist radon entry and prepare the building for post-construction radon mitigation, if necessary (see Figure AF103). These techniques are required in areas where designated by the jurisdiction.

AF103.2 Subfloor preparation. Radon Rough-In A radon rough-in is required for all foundation types, including crawlspace, basement, slab on grade, and slab on grade garage located below a living area as shown in Figure AF103.2. The rough-in shall be installed prior to pouring of concrete slabs, closure of building cavities, and installation of finish materials. Layer of gas-permeable material shall be placed under all concrete slabs and other floor systems that directly contact the ground and are within the walls of the living spaces of the building, to facilitate future installation of a subslab depressurization system, if needed. The gas-permeable layer shall consist of one of the following:

1. A uniform layer of clean aggregate, not less than 4 inches (102 mm) thick. The aggregate shall consist of material that will pass through a 2-inch (51 mm) sieve and be retained by a 1/4-inch (6.4 mm) sieve.
2. A uniform layer of sand (native or fill), not less than 4 inches (102 mm) thick, overlain by a layer or strips of geotextile drainage matting designed to allow the lateral flow of soil gases.
3. Other materials, systems or floor designs with demonstrated capability to permit depressurization across the entire subfloor area.

Delete and substitute as follows:
FIGURE AF103
RADON-RESISTANT CONSTRUCTION DETAILS FOR FOUR FOUNDATION TYPES
FIGURE AF103.2
FOUNDATION TYPES

Revise as follows:

**AF103.6 AF103.3 Passive subslab sub-slab depressurization system. system rough-in.** In basement or slab-on-grade buildings, the following components of a passive subslab sub-slab depressurization system shall be installed during construction in accordance with Sections AF103.3.1 through AF103.3 and AF103.5 through AF103.6.5.

Add new text as follows:

**AF103.3.1 Gas Permeable Layer** A gas-permeable layer shall be constructed under all concrete slabs and other floor systems that directly contact the ground and are within the walls of the living spaces of the building. The gas-permeable layer shall consist of one of the following:

1. A uniform layer of clean aggregate, not less than 4 inches [102 mm] in depth, shall be placed over the soil. The aggregate shall have a void ratio of not less than 35 percent or a Size Number 4, 5, 56, or 6 as classified by ASTM C33.
2. A uniform layer of native or fill sand, a minimum of 4 inches [102 mm] in depth, overlain by a layer or strips of geotextile drainage matting. The geotextile drainage matting shall have a cross-sectional area of at least 12 square inches [774 sq mm]. The closest edge of the geotextile matting shall be placed no closer than 12 inches [305 mm] to the foundation wall around the interior of the foundation perimeter.
3. A loop of 4 inch [102 mm] nominal or larger size perforated pipe placed in a trench along the perimeter of the foundation, with the trench backfilled with clean aggregate having a void ratio of not less than 35 percent or a Size Number 4, 5, 56, or 6 as classified by ASTM C33 such that the pipe is surrounded by aggregate for at least 1/3 of the outside pipe circumference. The pipe shall be placed no closer than 12 inches [305 mm] to the foundation wall around the interior of the foundation perimeter.
4. A loop of interconnected stay-in-place forms used to cast the foundation footing in accordance with 404.1.3.3.6 that is left in place to provide ground water control and provide a separate channel above the ground water channel for soil gas ventilation, with a cross sectional area no less than 12 square inches [77 sq. cm].
5. Other materials, systems or floor designs with demonstrated capability to allow the lateral flow of soil gases from across the entire sub-floor area.

**AF103.3.2 Vent pipe connector.** A 4 inch [102 mm] nominal diameter tee fitting or equivalent method shall be used to secure the vent pipe opening within the gas permeable layer. Not less than 4 feet [1219 mm] of perforated pipe or geotextile matting shall be connected to each of the two horizontal openings of the tee fitting or the two horizontal openings shall be connected to the interior drain tile system. Alternatively, a sealed sump
cover where the sump communicates directly with the sub-slab aggregate or communicates with it through a drainage system, shall secure the vent pipe opening. A flexible rubber coupling connector shall be provided at the sump cover connection to facilitate servicing the sump.

Revise as follows:

**AF103.3 AF103.3.3 Soil-gas-retarder.** A minimum 6-mil (0.15 mm) [or 3-mil (0.075 mm) cross-laminated] polyethylene or equivalent flexible sheeting material shall be placed on top of the gas-permeable layer prior to casting the slab or placing the floor assembly to serve as a soil-gas-retarder by bridging any cracks that develop in the slab or floor assembly, and to prevent concrete from entering the void spaces in the aggregate base material. The sheeting shall cover the entire floor area with separate sections of sheeting lapped not less than 12 inches (305 mm). The sheeting shall fit closely around any and extend up the surrounding foundation walls not less than 4 inches [101 mm]. Openings in the sheeting caused by pipe, wire or other penetrations of the material shall be sealed. Punctures or tears in the material shall be sealed or covered with additional sheeting.

**AF103.5 AF103.4 Passive submembrane Sub-membrane depressurization system.** In buildings with a crawl space foundation, the following components of a passive submembrane sub-membrane depressurization system shall be installed during construction. Construction in accordance with Sections AF103.4.1 through AF103.6.5.

**Exceptions:**

1. Buildings in which an approved mechanical crawl space ventilation system or other equivalent system is installed, is installed.

2. Where the soil gas retarder will be covered with concrete, the requirements of Section AF103.3.2 shall apply.

**AF103.5.3 AF103.4.1 Vent pipe. pipe connector.** A plumbing tee or other approved connection fitting shall be inserted horizontally beneath the sheeting and connected to a 3- or 4-inch diameter (76 or 102 mm) fitting with a vertical vent pipe installed through the sheeting. The vent pipe shall be extended up through the building floors, and terminate not less than 12 inches (305 mm) above the roof in a location not less than 10 feet (3048 mm) away from any window or other opening into the conditioned spaces of the building that is less than 2 feet (610 mm) below the exhaust point, and 10 feet (3048 mm) from any window or other opening in adjoining or adjacent buildings. The soil gas membrane with not less than 10 feet of perforated pipe connected to each of the two horizontal openings of such fitting or the two horizontal openings of the tee fitting shall connect to the interior drain tile system. The branch opening of the tee fitting shall be connected to the vent pipe in accordance with Section AF103.5.

**AF103.5.2 AF103.4.2 Soil-gas-retarder. Soil gas membrane.** The soil in crawl spaces shall be covered with a continuous layer of minimum 6 mil (0.15 mm) polyethylene soil-gas-retarder. The ground cover soil gas membrane complying with ASTM E1745 Class A, B or C. The membrane shall be lapped not less than 42-6 inches (305-152 mm) at joints and shall extend upwards 12 inches (305 mm) and be sealed to all foundation walls enclosing the crawl space area. Seams shall be sealed with polyurethane caulk complying with ASTM C920 class 25 or higher, or taped or equivalent method, installed in accordance with the manufacturer’s recommendations.

**AF103.6.1 AF103.5 Vent pipe.** A minimum 3-inch diameter (76 mm) ABS, PVC or equivalent 3 inch [76 mm] nominal size or larger gas-tight pipe shall be embedded vertically into the subslab aggregate or other permeable material before the slab is cast. A “T” fitting or equivalent method shall be used to ensure that the pipe opening remains within the subslab permeable material. Alternatively, the 3-inch (76 mm) pipe shall be inserted directly into an interior perimeter drain tile loop or through a sealed sump cover where the sump is exposed to the subslab aggregate or connected to it through a drainage system.
The pipe shall be extended extended from the tee fitting up through the building floors, in accordance with Sections AF103.5.1 through AF103.5.6. Materials used shall comply with Section P3002.1, and terminate not less than 12 inches (305 mm) above the surface of the roof in a location not less than 10 feet (3048 mm) away from any window or other opening into the conditioned spaces of the building that is less than 2 feet (610 mm) below the exhaust point, and 10 feet (3048 mm) from any window or other opening in adjoining or adjacent buildings.

AF103.5.1 Ventilation. Vent pipe termination. Crawl spaces shall be provided with vents to the exterior of the building. The minimum net area of ventilation openings shall comply with Section R408.1. The vent pipe shall terminate vertically upward not less than 12 inches [305 mm] above the roof and in a location not less than two feet [51 mm] vertically above, or not less than 10 feet [3048 mm] measured in any other direction, from openings in the building and adjacent buildings including windows, doors and other gravity air intake openings, exclusive of attic ventilation openings. Where a screen is installed on the terminus of radon exhaust pipe to prevent the entry of animals, such screen shall have a mesh size with a dimension of not less than 0.5 inch (12.7 mm).

AF103.5.2 Vent pipe drainage. Components of the radon vent pipe system shall be installed to provide positive condensate drainage to the ground beneath the slab or soil gas retarder membrane. The pipe shall not be trapped and shall have a minimum slope of one-eighth inch per foot (1 percent slope).

AF103.5.3 Vent pipe identification. Exposed and visible interior radon vent pipes shall be identified with not less than one label on each floor and in accessible attics. The label shall read: “Radon Reduction System.” “This pipe is a component of a radon control system. A radon test is necessary to verify that the radon level is below the level recommended by the US EPA.” The height of the label lettering shall be not less than 0.25 inch [6.35 mm].

AF103.5.4 Combination foundations. Combination basement/crawl space or slab on grade/crawl space foundations shall have separate radon vent pipes installed in each type of foundation area. Each radon vent pipe shall terminate above the roof or shall be connected. Where more than one type of foundation is present, each foundation area shall have a separate radon vent pipe and soil gas collector. Vent pipes shall connect to a single vent that terminates above the roof or each individual vent pipe shall terminate separately above the roof.

AF103.5.5 Multiple vent pipes. Separate foundation areas. In buildings where interior footings or other barriers separate the subslab aggregate or other gas-permeable material foundation areas, each area shall be fitted with an individual vent pipe or a pipe loop or equivalent method shall connect such areas below the slab. Vent pipes shall connect to a single vent that terminates above the roof or each individual vent pipe shall terminate separately above the roof.

Add new text as follows:

AF103.5.6 Provisions for radon fan. To facilitate possible installation of a radon fan, compliance with Sections AF103.5.6.1 through AF103.5.6.3 shall be required.

Revise as follows:

AF103.5.6.1 Vent pipe accessibility. Radon vent pipes shall be accessible for future fan installation through provided with access in an attic or other area outside the habitable space for the purpose of installing a fan. The pipe shall be centered in an unobstructed cylindrical space having a vertical height of not less than 48 inches [122 cm] and a diameter of not less than 21 inches [53 cm] in the location where a fan would be installed.

Exception: Where an approved electrical supply is installed on the roof.
need not be accessible in an attic space where an approved roof-top electrical supply is provided for future use.

Add new text as follows:

**AF103.5.6.2 Radon fan location.** Fans shall be located outdoors, in attics or in garages that are not beneath conditioned spaces. Fans shall not be installed below ground, in conditioned spaces, in occupiable spaces of a building or in any basement, crawlspace or other interior location that is directly beneath a conditioned or occupiable space of a building. Fans shall not be installed in any location where pipe positively pressured by the fan would be located inside conditioned or occupiable space.

Revise as follows:

**AF103.12 AF103.5.6.3 Power source.** To provide for future installation of an active submembrane or subslab depressurization system, a radon fan, an electrical circuit terminated that terminates in an approved junction box shall be installed during construction in the attic or other anticipated location of vent pipe fans. An electrical supply shall be accessible in anticipated locations of system failure alarms of a fan.

**AF103.4 AF103.6 Entry routes.** Potential radon entry routes shall be closed in accordance with Sections AF103.4.1- AF103.6.1 through AF103.4.10- AF103.6.5.

**AF103.4.1 AF103.6.1 Floor openings.** Openings around bathtubs, showers, water closets, pipes, wires or other objects that penetrate concrete slabs or other floor assemblies shall be filled with a polyurethane caulk or equivalent sealant applied in accordance with the manufacturer's recommendations, sealed in a permanent manner. Exception: Sealing is not required for floors above conditioned spaces.

**AF103.4.2 AF103.6.2 Concrete joints.** Control joints, isolation joints, construction joints, and any other joints in concrete slabs or between slabs and foundation walls shall be sealed with a caulk or sealant. Gaps and joints shall be cleared of loose material and filled with polyurethane caulk or other elastomeric sealant applied complying with ASTM C920 class 25 or higher or equivalent method installed in accordance with the manufacturer's recommendations.

**AF103.4.4 AF103.6.3 Sumps.** Sump pits open to soil or serving as the termination point for subslab or exterior drain tile loops shall be covered with a gasketed or otherwise sealed lid. Sumps used as the suction point in a subslab depressurization system shall have a lid designed to accommodate the vent pipe. Sumps used as a floor drain shall have a lid equipped with a trapped inlet.

**AF103.4.5 AF103.6.4 Foundation walls.** Hollow block masonry foundation walls shall be constructed with either a continuous course of solid masonry, one course of masonry grouted solid, or a solid concrete beam at or above finished ground surface to prevent the passage of air from the interior of the wall into the living space. Where a brick veneer or other masonry ledge is installed, the course immediately below that ledge shall be sealed. Joints, cracks and other openings around all penetrations of both exterior and interior surfaces of masonry block or wood foundation walls below the ground surface shall be filled with polyurethane caulk or equivalent sealant, complying with ASTM C920 class 25 or higher, or equivalent method installed in accordance with the manufacturer's recommendations. Penetrations of concrete walls shall be filled.

**AF103.4.10 AF103.6.5 Crawl space access.** Access doors and other openings or penetrations between basements and adjoining crawl spaces shall be closed, gasketed or otherwise filled to prevent air leakage. Exception: Air sealing is not required for conditioned crawl spaces.

Delete without substitution:

**AF103.4.3 Condensate drains.** Condensate drains shall be trapped or routed through nonperforated pipe to daylight.
AF103.4.6 Dampproofing. The exterior surfaces of portions of concrete and masonry block walls below the ground surface shall be dampproofed in accordance with Section R406.

AF103.4.7 Air-handling units. Air-handling units in crawl spaces shall be sealed to prevent air from being drawn into the unit.

**Exception:** Units with gasketed seams or units that are otherwise sealed by the manufacturer to prevent leakage.

AF103.4.8 Ducts. Ductwork passing through or beneath a slab shall be of seamless material unless the air-handling system is designed to maintain continuous positive pressure within such ducting. Joints in such ductwork shall be sealed to prevent air leakage. Ductwork located in crawl spaces shall have seams and joints sealed by closure systems in accordance with Section M1601.4.1.

AF103.4.9 Crawl space floors. Openings around all penetrations through floors above crawl spaces shall be caulked or otherwise filled to prevent air leakage.

AF103.11 Building depressurization. Joints in air ducts and plenums in unconditioned spaces shall meet the requirements of Section M1601. Thermal envelope air infiltration requirements shall comply with the energy conservation provisions in Chapter 11. Fireblocking shall meet the requirements contained in Section R302.11.
The U.S. Environmental Protection Agency (EPA) recommends that homes that measure 4 pCi/L and greater be mitigated.

The EPA and the U.S. Geological Survey have evaluated the radon potential in the United States and have developed a map of radon zones designed to assist building officials in deciding whether radon-resistant features are applicable in new construction.

The map assigns each of the 3,141 counties in the United States to one of three zones based on radon potential. Each zone designation reflects the average short-term radon measurement that can be expected to be measured in a building without the implementation of radon-control methods. The radon zone designation of highest priority is Zone 1. Table AF101 lists the Zone 1 counties illustrated on the map. More detailed information can be obtained from state-specific booklets (EPA-402-R-93-021 through 070) available through State Radon Offices or from EPA Regional Offices.

FIGURE AF101
EPA MAP OF RADON ZONES
Add new standard(s) as follows:

TABLE AF101(4)
HIGH RADON-POTENTIAL (ZONE 1) COUNTIES

Delete table in its entirety
E1745: Standard Specification for Plastic Water Vapor Retarders Used in Contact with Soil or Granular Fill under Concrete Slabs

Reason: This code change proposal improves Appendix F by clarifying some construction details, resolving longstanding editorial issues and addressing a few significant installation problems that impact the effectiveness of radon control in new construction.

The requirement subsections are renumbered to facilitate deletions of redundant material and reorganization. The narrative statement below refers to the subsection numbers in the proposed text.

- Additional detail has been provided on the vent pipe connector in Section AF103.3.3, the connection between the vertical radon vent pipe and the gas permeable layer below the crawl space or slab. This connection has suffered from consistent clogging with soil, concrete and/or gravel. A requirement for a couple of short lengths of perforated piping in the gas permeable layer and clarification that the tee fitting shall secure the vent pipe will largely prevent this clogging.

- Another latent problem which occurs often in the field is that the vent piping is routed through the attic space without allowing access to the vent pipe and leaving insufficient headroom for a fan if system activation is required. Space considerations are provided to address this problem in Section AF103.5.6. Fan installation remains outside of the scope of AF103.5.6.

- Section AF103.4.1, the required 12-inch lapping of joints is reduced to 6 inches, and extension of the soil gas retarder upward on foundation walls for subslabs is added to match the extension on walls for crawl spaces.

- Clearances to prevent radon entry from the exhaust pipe are clarified, and prevention of pipe obstruction by screening material is added, both within Section AF03.5.1.

- In Section AF103.5.3, the vent pipe identification is expanded to clarify the limit of Appendix F radon control.

- Lack of sealing of the submembrane soil gas retarder creates problems in systems installed in homes with crawl spaces. In this proposal, sealing is added (except for where the crawl space will be covered by concrete and where crawl space ventilation exists) to

Several editorial changes clarify and simplify the Appendix without expanding requirements. Along with some fairly self-explanatory edits, these changes include:

- Section AF101 specifies that the scope of the appendix is “radon control methods in new construction.”

- Section AF101 would no longer include references to EPA radon zone 1, zone 1 county lists, or the EPA radon map. Voluntary use of the Appendix by builders and adoptions in jurisdictions beyond Zone 1 reduce the applicability of these materials. According to the Home Innovations Research Lab report “Radon-Resistant Construction Practices in New U.S. Homes 2016” [see bibliography] 24% of 2016 homes in Zone 2 were built with radon control. In 2016 the State of Connecticut adopted radon control for all counties; previously Minnesota and Illinois did the same. Local jurisdictions are adopting the Appendix.

- In AF102, the definition of radon gas is simplified, a universal term, radon rough-in, is added to clarify the type of system allowed by Appendix F, and duplicative references to active and passive subslab methods are deleted in favor of a single definition for subslab systems.
• In Section AF103.3.1 Gas Permeable Layer, an option for using stay-in-place forms per 404.1.3.3.6 is added to the choices, and the specification allowing for “the lateral flow of gases” is moved from the initial sentence to the fifth and final option.
• The description of materials for vent pipes in Section AF103.5 was changed from “ABS, PVC or equivalent” to “comply with P3002.1.”
• Redundancies with other code requirements for ventilation, foundation and condensate drains, damp proofing, and air handler sealing have been removed.
• An exception for sealing for floors above conditioned spaces is added in AF 103.6.1.
• Sealing requirements for control joints were eliminated in AF 103.6.2.

Most of the changes in this proposal were presented by the proponent in code change proposal or public comment in 2016.

Below for ease of review is the text that would result from the proposed revisions:

APPENDIX F

RADON CONTROL METHODS
AF101.1 General. This appendix contains requirements for radon control methods in new construction.

SECTION AF102 DEFINITIONS
AF102.1 General. For the purpose of these requirements, the terms used shall be defined as follows:
RADON GAS. The element Rn-222, which is a radioactive, colorless, odorless, tasteless, cancer-causing gas that occurs naturally as a decay product of radium.
RADON ROUGH-IN. The installation of all parts and materials of submembrane or subslab depressurization system including gas permeable layers, soil gas retarders, membranes, piping, connectors, terminations, and power sources.
SOIL-GAS-RETARDER. A continuous membrane of 6-mil [0.15 mm] polyethylene or other equivalent material used to retard the flow of soil gases into a building.
SUBMEMBRANE DEPRESSURIZATION SYSTEM. System designed to achieve lower sub-membrane air pressure relative to crawl space air pressure by use of a fan powered vent drawing air from beneath the soil gas retarder membrane.
SUBSLAB DEPRESSURIZATION SYSTEM. System designed to achieve lower sub-slab air pressure by use of a fan-powered vent drawing air from beneath the floor slab.

SECTION AF103 REQUIREMENTS
AF103.1 General. AF103 is intended to reduce radon entry and prepare the building for post-construction radon mitigation if necessary.
AF103.2 Radon Rough-in. A rough-in is required for all foundation types, including crawlspace, basement, slab on grade, and slab on grade garage located below a living area as shown in Figure AF103.2. The rough-in shall be installed prior to pouring of concrete slabs, closure of building cavities, and installation of finish materials. Figure AF103.2 Foundation Types
AF103.3 Sub-slab depressurization system rough-in. In basement or slab-on-grade buildings, the components of a sub-slab depressurization system shall be installed during construction in accordance with AF103.3.1 through AF103.3 and AF103.5 through AF103.6.5.
AF103.3.1 Gas permeable layer. A gas-permeable layer shall be constructed under all concrete slabs and other floor systems that directly contact the ground and are within the walls of the living spaces of the building. The gas-permeable layer shall consist of one of the following:
A uniform layer of clean aggregate, not less than 4 inches [102 mm] in depth, shall be placed over the soil. The aggregate shall have a void ratio of not less than 35 percent or a Size Number 4, 5, 56, or 6 as classified by
A uniform layer of native or fill sand, a minimum of 4 inches [102 mm] in depth, overlain by a layer or strips of geotextile drainage matting. The geotextile drainage matting shall have a cross-sectional area of at least 12 square inches [774 sq mm]. The closest edge of the geotextile matting shall be placed no closer than 12 inches [305 mm] to the foundation wall around the interior of the foundation perimeter.

A loop of 4 inch [102 mm] nominal or larger size perforated pipe placed in a trench along the perimeter of the foundation, with the trench backfilled with clean aggregate having a void ratio of not less than 35 percent or a Size Number 4, 5, 56, or 6 as classified by ASTM C33 such that the pipe is surrounded by aggregate for at least 1/3 of the outside pipe circumference. The pipe shall be placed no closer than 12 inches [305 mm] to the foundation wall around the interior of the foundation perimeter.

A loop of interconnected stay-in-place forms used to cast the foundation footing in accordance with 404.1.3.3.6 that is left in place to provide ground water control and provide a separate channel above the ground water channel for soil gas ventilation, with a cross sectional area no less than 12 square inches [77 sq. cm]. Other materials, systems or floor designs with demonstrated capability to allow the lateral flow of soil gases from across the entire sub-floor area.

AF103.3.2 Vent pipe connector. A 4 inch [102 mm] nominal diameter tee fitting or equivalent method shall be used to secure the vent pipe opening within the gas permeable layer. Not less than 4 feet [1219 mm] of perforated pipe or geotextile matting shall be connected to each of the two horizontal openings of the tee fitting or the two horizontal openings shall be connected to the interior drain tile system. Alternatively, a sealed sump cover where the sump communicates directly with the sub-slab aggregate or communicates with it through a drainage system, shall secure the vent pipe opening. A flexible rubber coupling connector shall be provided at the sump cover connection to facilitate servicing the sump.

AF103.3.3 Soil gas retarder. A minimum 6-mil [0.006 in; 0.15 mm] (or 3-mil [0.003 in; 0.075 mm] cross-laminated) polyethylene or equivalent flexible sheeting material shall be placed on top of the gas permeable layer prior to casting the slab or placing the floor assembly. The sheeting shall cover the entire floor area with separate sections of sheeting lapped not less than 12 inches [305 mm] and extend up the surrounding foundation walls not less than 4 inches [101 mm]. Openings in the sheeting caused by pipe, wire and other penetrations shall be sealed. Punctures or tears in the material shall be sealed or covered with additional sheeting. AF103.4 Sub-membrane depressurization system rough-in. In buildings with a crawl space foundation, the components of a sub-membrane depressurization system shall be installed during construction in accordance with AF103.4.1 through AF103.6.5.

Exceptions:

Buildings in which an approved mechanical crawl space ventilation system is installed.

Where the soil gas retarder will be covered with concrete, the requirements of 103.3.2 shall apply.

AF103.4.1 Vent pipe connector. A tee fitting shall be installed beneath the soil gas membrane with not less than 10 feet of perforated pipe connected to each of the two horizontal openings of such fitting or the two horizontal openings of the tee fitting shall connect to the interior drain tile system. The branch opening of the tee fitting shall be connected to the vent pipe in accordance with section AF103.5.

AF103.4.2 Soil gas membrane. The soil in crawl spaces shall be covered with a continuous layer of soil gas membrane complying with ASTM E1745 Class A, B or C. The membrane shall be lapped not less than 6 inches [152 mm] at joints and shall extend upwards 12 inches [305 mm] and be sealed to all foundation walls enclosing the crawl space area. Seams shall be sealed with polyurethane caulk complying with ASTM C920 class 25 or higher, or taped or equivalent method, installed in accordance with the manufacturer’s recommendations.

AF103.5 Vent pipe. A 3 inch [76 mm] nominal size or larger gas-tight pipe shall be extended from the tee fitting up through the building floors and in accordance with Sections AF103.5.1 through AF103.5.6. Materials used shall comply with P3002.1.

AF103.5.1 Vent pipe termination. The vent pipe shall terminate vertically upward not less than 12 inches [305 mm] above the roof and in a location not less than two feet [51 mm] vertically above, or not less than 10 feet [3048 mm] measured in any other direction from, openings in the building and adjacent buildings including windows, doors and other gravity air intake openings, exclusive of attic ventilation openings. Where a screen is installed on the terminus of radon exhaust pipe to prevent the entry of animals, such screen shall have a mesh
size with a dimension of not less than 0.5 inch (12.7 mm).

AF103.5.2 Vent pipe drainage. The radon vent pipe shall be installed to provide condensate drainage to the ground beneath the slab or membrane. The pipe shall not be trapped and shall have a minimum slope of one-eighth inch per foot (1 percent slope).

AF103.5.3 Vent pipe identification. Exposed and visible interior radon vent pipes shall be identified with not less than one label on each floor and in accessible attics. The label shall read “This pipe is a component of a radon control system. A radon test is necessary to verify that the radon level is below the level recommended by the US EPA.” The height of the label lettering shall be not less than 0.25 inch (6.35 mm).

AF103.5.4 Combination foundations. Where more than one type of foundation is present, each foundation area shall have a separate radon vent pipe and soil gas collector. Vent pipes shall connect to a single vent that terminates above the roof or each individual vent pipe shall terminate separately above the roof.

AF103.5.5 Separate foundation areas. In buildings where interior footings or other barriers separate foundation areas, each area shall be fitted with an individual vent pipe or a pipe loop or equivalent method shall connect such areas below the slab. Vent pipes shall connect to a single vent that terminates above the roof or each individual vent pipe shall terminate separately above the roof.

AF103.5.6 Provisions for radon fan. To facilitate possible installation of a radon fan, the following shall be provided:

AF103.5.6.1 Vent pipe accessibility. The radon vent pipes shall be provided with access in an attic or other area outside the habitable space for the purpose of installing a fan. The pipe shall be centered in an unobstructed cylindrical space having a vertical height of not less than 48 inches (122 cm) and a diameter of not less than 21 inches (53 cm) in the location where a fan would be installed.

Exception: Where an approved electrical supply is installed on the roof for future use.

AF103.5.6.2 Radon fan location. Fans shall be located outdoors, in attics or in garages that are not beneath conditioned spaces. Fans shall not be installed below ground, in conditioned spaces, in occupiable spaces of a building or in any basement, crawlspace or other interior location that is directly beneath a conditioned or occupiable space of a building. Fans shall not be installed in any location where pipe positively pressured by the fan would be located inside conditioned or occupiable space.

AF103.5.6.3 Power source. To provide for future installation of a radon fan, an electrical circuit that terminates in an approved junction box shall be installed in the attic or other anticipated location of a fan.

AF103.6 Entry routes. Potential radon entry routes shall be closed in accordance with Sections AF103.6.1 through AF103.6.5.

AF103.6.1 Floor openings. Openings around bathtubs, showers, water closets, pipes, wires and other objects that penetrate concrete slabs or floor assemblies shall be sealed in a permanent manner.

Exception: Sealing is not required for floors above conditioned spaces.

AF103.6.2 Concrete joints. Isolation joints, construction joints and other joints in concrete slabs and between slabs and foundation walls shall be sealed with a caulking or sealant. Gaps and joints shall be cleared of loose material and filled with polyurethane caulk complying with ASTM C920 class 25 or higher or equivalent method installed in accordance with the manufacturer’s recommendations.

AF103.6.3 Sumps. Sump pits open to soil or serving as the termination point for subslab or exterior drain tile loops shall be covered with a gasketed or otherwise sealed lid. Sumps used as a suction point in a subslab depressurization system shall have a lid designed to accommodate the vent pipe. Sumps used as a floor drain shall have a lid equipped with a trapped inlet.

AF103.6.4 Foundation walls. Hollow block masonry foundation walls shall be constructed with a continuous course of solid masonry, one course of masonry grouted solid, or a solid concrete beam at or above finished grade to prevent passage of air from the interior of the wall into the living space. Where a brick veneer or other masonry ledge is installed, the course immediately below that ledge shall be sealed. Joints, cracks and other openings around penetrations of both exterior and interior surfaces of masonry block and wood foundation walls below the ground surface shall be filled with polyurethane caulk complying with ASTM C920 class 25 or higher, or equivalent method installed in accordance with the manufacturer’s recommendations. Penetrations of concrete walls shall be sealed.

AF103.6.5 Crawl space access. Access doors and other openings or penetrations between basements and
adjoining crawl spaces shall be closed, gasketed or otherwise filled to prevent air leakage. Exception: Air sealing is not required for conditioned crawl spaces.

**Cost Impact:** The code change proposal will increase the cost of construction.

The additional cost of the code change in materials is $25: $10 for 10 feet of 4” perforated pipe; $10 for caulk to seal the soil gas retarder and $5 in additional cost for soil retarder material on walls (offset by the reduction in soil retarder material needed to overlap seams). There is also a labor cost component which is minimal for the perforated pipe and variable for the sealing depending on the area of the crawl space.

Installation of the existing Appendix F in a single family home is documented in the Home Innovation Research Labs’ 2016 report on radon-resistant construction practices [see bibliography]: "In 2016, the average installation cost for a passive system in a single-family detached home was approximately $374, up slightly from the $358 reported for 2015 and $332 reported for 2014."

**Staff Analysis:** A review of the standard proposed for inclusion in the code, ASTM E1745, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.
2018 International Residential Code

Add new text as follows:

**AF104 Testing.** Where radon-resistant construction is required, radon testing shall be as specified in Items 1 through 11:

1. **Testing shall be performed after the dwelling passes its air tightness test.**
2. **Testing shall be performed after the radon control system and HVAC installations are complete. The HVAC system shall be operating during the test. Where the radon system has an installed fan, the dwelling shall be tested with the radon fan operating.**
3. **Testing shall be performed at the lowest occupied floor level, whether or not that space is finished. Spaces that are physically separated and served by different HVAC systems shall be tested separately.**
4. **Testing shall not be performed in a closet, hallway, stairway, laundry room, furnace room, bathroom or kitchen.**
5. **Testing shall be performed with a commercially available radon test kit or with a continuous radon monitor that can be calibrated. Testing with test kits shall include two tests, and the test results shall be averaged. Testing shall be in accordance with this section and the testing device manufacturer's instructions.**
6. **Testing shall be performed with the windows closed. Testing shall be performed with the exterior doors closed, except when being used for entrance or exit. Windows and doors shall be closed for at least 12 hours prior to the testing.**
7. **Testing shall be performed by the builder, a registered design professional, or an approved third party.**
8. **Testing shall be conducted over a period of not less than 48 hours or not less that the period specified by the testing device manufacturer, whichever is longer.**
9. **Written radon test results shall be provided by the test lab or testing party. The final written test results shall be included with construction documents.**
10. **Where the radon test result is 4 pCi/L or greater, the fan for the radon vent pipe shall be installed as specified in Sections AF103.8 and AF103.12.**
11. **Where the radon test result is 4 pCi/L or greater, the system shall be modified and retested until the test result is less than 4 pCi/L.**

**Exception:** Testing is not required where the occupied space is located above an unenclosed open space.

**Reason:** Testing is the only way to know if radon levels are below the safety level. Radon is a tasteless colorless gas that can cause lung cancer. Radon tests are relatively simple and inexpensive. The jurisdiction decides if radon-resistant construction applies in the jurisdiction by adopting (or not adopting) Appendix F, most commonly adopting the Appendix F in radon zone 1. Both the occupants and the builder want to know that the radon mitigation system works. Where radon systems are required, consider this test commissioning for the radon system. Typically the inexpensive radon test kits are mailed off to a testing lab. The testing lab responds fairly quickly with written results. The “safety” level or range is a test below 4 pCi/L. Besides confirming compliance, written test results provide the owner with confirmation the home’s radon level is at or below the safety level. For unsold homes, written test results with the construction documents allow the future owner to know that the home passed its safety test.
Often homes will pass without installing the fan described in Appendix F, with is sometimes called a “passive” radon system. Where a passive system does not meet the safety level, adding a fan usually lowers the radon level to the safety range.

**Bibliography:** The American Cancer Society states that “The leading cause of lung cancer in non-smokers is exposure to radon gas.” (ref 1) The link between radon and lung cancer has been firmly established for about 20 years (ref 2). Radon is estimated to cause about 20,000 deaths per year from lung cancer (ref 2). Children exposed to high levels of radon are more likely to develop lung cancer later in life. (ref 3). Deaths from radon significantly exceed deaths from other building-related risks; such as fires, falls, electrocution, tornadoes, hurricanes, winds, fires, etc. In part this is because the codes have reduced these other risks, but have not addressed radon as well.

Radon “accounts for about 21,000 deaths from lung cancer each year.”

2) U.S. National Research Council Committee on the Biological Effects of Ionizing Radiation. 1999.

[https://www.nap.edu/read/5499/chapter/1#viii](https://www.nap.edu/read/5499/chapter/1#viii)  [https://www.nap.edu/read/5499/chapter/5#97](https://www.nap.edu/read/5499/chapter/5#97)

Historically the link between radon and lung cancer was not understood. Radon is an invisible, tasteless and odorless gas. There is a long period between exposure to radon and the symptoms of lung cancer. Recognition that radon increased lung cancers came from early studies of uranium miners, and was later confirmed more broadly.

[https://www.nap.edu/read/5499/chapter/5#97](https://www.nap.edu/read/5499/chapter/5#97)

In 1999 it was concluded that residential radon, as well as smoking, were the most important contributors to the lung cancer. Note table 3-10, summed “total male” and “total female” for both “ever-smokers” and “never-smokers” Actual value in table is 21,800, but is rounded to 21,000.

[https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3709356/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3709356/)

The study concluded: "... exposure to radon during childhood increases the lifetime risk of developing lung cancer ... if a child lived in a home with very high radon concentration for only a few years, the risk of developing lung cancer later in the life could be equivalent to a lifetime exposure to moderate radon concentration."

**Cost Impact:** The code change proposal will increase the cost of construction Radon test kits are inexpensive, less than $50 for the two tests including laboratory determination of results. Tests by radon professionals will likely be more expensive.

Proposal # 5548

RB289-19
2018 International Residential Code

Revise as follows:

AJ102.4.4 Window control devices. Where window fall prevention devices complying with ASTM F2090 are not provided, window opening control devices complying with ASTM F2090 shall be installed where an existing window, including the sash and glazed portion, is replaced and where all of the following apply to the replacement window:

1. The window is operable.
2. The window replacement includes replacement of the sash and the frame.
3. The top of the sill of the window opening is at a height less than 24 inches (610 mm) above the finished floor.
4. The window will permit openings that will allow passage of a 4-inch-diameter (102 mm) sphere where the window is in its largest opened position.
5. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit.

Reason: This revision makes it clear that regardless of whether replacing the entire existing window (sash and frame), or the sash and glazed portion with an insert window where the existing frame remains, the window fall prevention requirements apply in both applications which is consistent with how the code treats these replacements for energy efficiency.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The intent of this proposal is to ensure window fall prevention requirements are met as intended by the code. It does not have a direct impact on cost.
IRC®: AK102.1, AK103.1, ASTM Chapter 44 (New)

Proponent: Tim Earl, representing The Gypsum Association (tearl@gbhinternational.com)

2018 International Residential Code

Revise as follows:

AK102.1 General. Airborne sound insulation for wall and floor-ceiling assemblies shall meet a sound transmission class (STC) rating of 45 where tested in accordance with ASTM E90 or an apparent STC (ASTC) of 42 when tested in accordance with ASTM E90–E336. Penetrations or openings in construction assemblies for piping; electrical devices; recessed cabinets; bathtubs; soffits; or heating, ventilating or exhaust ducts shall be sealed, lined, insulated or otherwise treated to maintain the required ratings. Dwelling unit entrance doors, which share a common space, shall be tight fitting to the frame and sill.

AK103.1 General. Floor/ceiling assemblies between dwelling units, or between a dwelling unit and a public or service area within a structure, shall have an impact insulation class (IIC) rating of not less than 45 when tested in accordance with ASTM E492–E492 or an apparent IIC (AIIC) of 42 where tested in accordance with ASTM E1007.

Add new standard(s) as follows:

ASTM

ASTM International
100 Barr Harbor Drive, P.O. Box C700
West Conshohocken PA 19428

E336-17a: Standard Test Method for Measurement of Airborne Sound Attenuation between Rooms in Buildings

ASTM

ASTM International
100 Barr Harbor Drive, P.O. Box C700
West Conshohocken PA 19428

Reason: This creates the addition of the option for field testing for ASTC and AIIC – actual field measures versus laboratory measures - with slightly lower requirements for these versus the lab tested assemblies as they are actual numbers of in place systems. This begins to migrate the code to the more preferred field verified apparent measures as reflected in ICC G2-2010 guidance, in the IBC and in ASTM standards on sound, but still leaves it as just an option in an optional appendix.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This adds an optional method of testing, so it will not increase the cost of construction unless users choose this option, which would add approximately $1,500 to the cost of a home.

Proposal # 5049
2018 International Residential Code

Add new text as follows:

**AQ**

**Energy Conservation**

**AQ106.1 Testing for tiny houses.** The air leakage rate for tiny houses shall not exceed 0.30 cfm at 50 pascals of pressure per ft\(^2\) of the dwelling unit enclosure area. Testing shall be conducted in accordance with RESNET/ICC 380, ASTM E 779 or ASTM E 1827 and reported at a pressure of 0.2 inch w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weather stripping or other infiltration control measures.
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
3. Interior doors, if installed at the time of the test, shall be open.
4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed.
5. Heating and cooling systems, if installed at the time of the test, shall be turned off.
6. Supply and return registers, if installed at the time of the test, shall be fully open.

**AQ106.1.1 Whole house mechanical ventilation.** Where an air leakage rate not exceeding 0.30 cfm per ft\(^2\) of the dwelling unit enclosure area in accordance with Section AQ106.1 is provided, the tiny house shall be provided with whole house mechanical ventilation in accordance with Section M1505.4.

**AQ107.1 Tiny House.** Tiny houses shall be deemed to be in compliance with Chapter 11 of this code and Chapter R4 of the International Energy Conservation Code provided that the following conditions are met:

1. The insulation and fenestration meet the requirements of Table N1102.1.2
2. The thermal envelope meets the requirements of Section N1102.4.1.1 and Table N1102.4.1.1.
3. Solar, wind, or other renewable energy source supplies not less than 90 percent of the energy use for the structure.
4. Solar, wind, or other renewable energy source supplies not less than 90 percent of the energy for service water heating.
5. Permanently installed lighting is in accordance with Section R404.
6. Mechanical ventilation is provided in accordance with Section M1505 of this code. Operable fenestration is not used for ventilation.

**Reason:** The appendix currently states that tiny houses must comply with the code except for the following. There are some energy requirements that need to be adjusted for the unique construction of tiny houses. The current test parameters for air tightness are not conducive for houses with smaller volumes. The new testing
parameters and metrics will provide the ability for air leakage of the smaller structures and allowing for them to demonstrate compliance.

When testing to the new metrics there needs to be an understanding that when meeting the testing one must provide a whole house mechanical ventilation system.

This proposal addresses those tiny houses that build to be self-sufficient with their energy consumption. If they meet those requirements they should be considered to comply with the intent of the energy requirements.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction
These requirements while are already required would not increase the cost of construction. This proposal provide options for the type of construction that happens for tiny houses to obtain energy compliance.

**Staff Analysis:** A review of the standards proposed for inclusion in the code, RESNE/ICC 380, ASTM E779 and ASTM E1827, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 5539

RB292-19
2018 International Residential Code

Revise as follows:

AQ104.1.2 Minimum horizontal dimensions. Lofts shall be not less than 5 feet (1524 mm) in any horizontal dimension.

AQ104.1.3 Height effect on loft area. Portions of a loft with a sloped ceiling measuring less than 3 feet (914 mm) from the finished floor to the finished ceiling shall not be considered as contributing to the minimum required area for the loft. See Figure AQ104.1.3.

   Exception: Under gable roofs with a minimum slope of 6 units vertical in 12 units horizontal (50-percent slope), portions of a loft with a sloped ceiling measuring less than 16 inches (406 mm) from the finished floor to the finished ceiling shall not be considered as contributing to the minimum required area for the loft.

AQ104.2 Loft access and egress. The access to and primary egress from lofts shall be of any type described in Sections AQ104.2.1 through AQ104.2.4. The loft access and egress element along its required minimum width, shall meet the loft where its ceiling height is not less than 3 feet (914 mm).

AQ104.2.1 Stairways. Stairways accessing lofts shall comply with this code or with Sections AQ104.2.1.1 through AQ104.2.1.5. AQ104.2.1.7.

Revise as follows:

AQ104.2.1.2 Headroom. The headroom in above stairways accessing a loft shall be not less than 6 feet 2 inches (1880 mm), as measured vertically, from a sloped line connecting the tread, landing, or landing platform nosings in the middle center of their width, width, and vertically from the landing platform along the center of its width.

Add new text as follows:

AQ104.2.1.4 Landings. Intermediate landings and landings at the bottom of stairways shall comply with Section R311.7.6, except that the depth in the direction of travel shall be not less than 24 inches (610 mm).

Revise as follows:

AQ104.2.1.4 AQ104.2.1.5 Landing platforms. The top tread and riser of stairways accessing lofts shall be constructed as a landing platform where the loft ceiling height is less than 6 feet 2 inches (1880 mm) where the stairway meets the loft. The landing platform shall be 18 inches to 22 inches (457 to 559 mm) in width and in depth measured horizontally from and perpendicular to the nosing of the landing platform. The landing platform riser height to the edge of the loft and 16 to floor shall be not less than 16 inches (406 mm) and not greater than 18 inches (406 to 457 mm) in height measured from the landing platform to the loft floor.
Handrails. Handrails shall comply with Section R311.7.8.

Stairway guards. Guards at open sides of stairways, landings, and landing platforms shall comply with Section R312.1.

Loft Guards. Loft guards shall be located along the open side(s) of lofts. Loft guards shall be not less than 36 inches (914 mm) in height or one-half of the clear height to the ceiling, whichever is less. Loft guards shall comply with Section R312.1.3 and Table R301.5 for their components.

Add new text as follows:
**Figure AQ104.1.3**

**Loft Ceiling Height**

**Reason:** This proposal improves Appendix Q by 1) modifying the language in some sections to provide clarity, 2) adding Figure AQ104.1.3 from the Commentary to illustrate the meaning of "height effect, and 3) making other changes to the following sections:

AQ104.2: The added sentence requires the ceiling height of the loft to be a minimum of 3 feet where access and egress element meets the loft. This was previously unaddressed.

AQ104.2.1.2: The change at the end clarifies that the required ceiling height above a landing platform is measured from the landing platform itself, as opposed to a sloping line connecting the landing platform nosing and the loft nosing. This is because a person goes from a standing to a kneeling position when entering a loft from a landing platform.

AQ104.2.1.4: A new section on intermediate and bottom landings for stairways sets their minimum dimensions, which was previously unaddressed. The 24” dimension in the direction of travel is greater than that required for a landing platform (20”) because the nature of their use differs. A person goes from standing to kneeling at a landing platform to a loft (or vice versa), whereas a short, standing stride may be needed at an intermediate or bottom landing. The 24” dimension provides for that.

AQ104.2.5: The added sentence refers to related sections in the IRC to clarify that loft guard components must comply with those sections.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. The proposed changes clarify dimensional requirements and language and do not affect cost.
Proponent: Jay Hyde, representing Sacramento Valley Association of Building Officials
(jhyde@mogaveroarchitects.com)

2018 International Residential Code

Revise as follows:

AQ104.2.2.1 Size and capacity. Ladders accessing lofts shall have a rung width of not less than 12 inches (305 mm), and 10-inch (254 mm) to 14-inch (356 mm) spacing between rungs. Ladders shall be capable of supporting a 200-300-pound (75-136 kg) load on any rung. Rung spacing shall be uniform within 3⁄8 inch (9.5 mm).

Reason: The proposed 300 pound ladder capacity coordinates with IMC Section 306.5. According to the Centers for Disease Control, the average American male over 30 years of age is 180 pounds. The margin of safety at 200 pounds capacity is inadequate to protect the public.

Cost Impact: The code change proposal will increase the cost of construction
The code change proposal MAY increase the cost of construction.

Proposal # 1427
2018 International Residential Code

Revise as follows:

**CLAY SLIP.** A suspension of clay or clay subsoil particles in water.

**CLAY SUBSOIL.** Subsoil sourced directly from the earth or refined, containing clay and free from not more than trace amounts of organic matter.

Revise as follows:

- b. Water mixed with subsoil equals clay slip.
- c. Subsoil Testing Methods:
  - A. Lab test for percent of clay, silt and sand via hydrometer method.
  - B. The Figure 2 Ribbon Test or and the Figure 3 Ball Test in the Appendix of ASTM E2392/E2392M.
- d. Trace amounts of organic materials are acceptable.

**Reason:** The proposed changes to definitions improve clarity and provide consistency with language in footnote 'd' in Table AR103.2.3 and with definitions in Appendix S. The proposed changes to footnote 'c' in Table AR103.2.3 clarifies the referenced test's location, and corrects for the intention that both tests are required to determine subsoil suitability.
Cost Impact: The code change proposal will not increase or decrease the cost of construction. The proposed changes for clarity and consistency do not affect cost.
Add new text as follows:

**BRACED WALL PANEL, STRAWBALE.** A strawbale wall designed and constructed to resist in-plane shear loads through the interaction of the stacked straw bales, the reinforced plaster and its connections to the top plate, sill plates and foundation. The panel’s length meets the requirements for the particular wall type and contributes toward the total amount of bracing required along its braced wall line in accordance with Sections AS106.13 and R602.10.1.

**CLAY.** Inorganic soil with particle sizes less than 0.00008 inch (0.002 mm) having the characteristics of high to very high dry strength and medium to high plasticity, used as the binder of other component materials in clay plaster and straw-clay.

Revise as follows:

**CLAY SLIP.** A suspension of clay or clay subsoil particles in water.

**CLAY SUBSOIL.** Subsoil sourced directly from the earth or refined, containing clay and free sand and silt, and not more than trace amounts of organic matter.

**FINISH.** Completed combination of materials on the interior or exterior faces of stacked bales.

**PLASTER.** Gypsum plaster, cement plaster, clay plaster, soil-cement plaster, lime plaster or cement lime plaster, clay, soil-cement, gypsum, lime, clay-lime, lime-cement, or cement plaster, as described in Section AS104.

Revise as follows:

**PRECOMPRESSION.** Vertical compression of stacked bales before the application of finish.

Add new text as follows:

**ROOF BEARING ASSEMBLY** In load-bearing strawbale walls, a structural assembly at the top of the wall that bears and distributes roof loads to the wall.
SHEAR WALL. A strawbale wall designed and constructed to resist in-plane lateral seismic and wind forces parallel to the plane of the wall in accordance with Section AS106.13. Synonymous with braced wall panel.

AS103.1 Shape. Bales shall be rectangular in shape, except for partial bales made to fill non-rectangular spaces in accordance with AS103.6.

AS103.3 Ties. Bales shall be confined by synthetic fiber, natural fiber or metal ties sufficient to maintain required bale density. Ties shall be not less than 3 inches (76 mm) and not more than 6 inches (152 mm) from the two untied faces without ties and shall be spaced not more than 12 inches (305 mm) apart. Bales with broken ties shall be retied with sufficient tension to maintain required bale density.

AS103.7 Types of straw. Bales shall be composed of straw from wheat, rice, rye, barley or oat. The dry stems of other cereal grains or similar crops shall be acceptable where approved by the building official. Bales shall not be composed of hay.

AS103.8 Other baled material. Orientation of bales. The dry stems of other cereal grains shall be acceptable where approved by the building official. Straw bales shall be placed laid flat, on-edge, or on-end in accordance with this appendix.

AS104.1 General. Finishes applied to strawbale walls shall be any type permitted by this code, and shall comply with this section and with Chapters 3 and 7 unless stated otherwise in this section: plasters in accordance with Section AS104.4, or non-plaster exterior wall coverings in accordance with Section R703 and other finish systems complying with all of the following:

1. With approved specifications and details showing the finish system’s means of attachment to the wall or its independent support, and a means of draining or evaporating water that penetrates the exterior finish to the exterior.
2. The vapor permeance of the combination of finish materials shall be 5 perms or greater to allow the transpiration of water vapor through the wall.
3. Finish systems with weights >10 and ≤ 20 pounds per square foot (> 48.9 and ≤ 97.8 kg/m²) of wall area require a factor of 1.2 for minimum total length of braced wall panels in Table AS106.13(3).
4. Finish systems with weights > 20 pounds per square foot (97.8 kg/m²) of wall area require an engineered design.

Revise as follows:

AS104.2 Purpose, and where required. Strawbale walls shall be finished so as to provide mechanical protection, fire resistance and protection from weather and to restrict the passage of air through the bales, in accordance with this appendix and this code. Vertical strawbale wall surfaces shall receive a coat of plaster not less than 3/8 inch (10 mm) thick, or greater where required elsewhere in this appendix, or shall fit tightly against a solid wall panel or dense-packed cellulose insulation with a density of not less than 3.5 pounds per cubic foot (56 kg/m³) blown into an adjacent framed wall. The tops of strawbale walls shall receive a coat of plaster not less than 3/8 inch (10 mm) thick where straw would otherwise be exposed, or be tightly covered by gypsum board or a roof bearing assembly.

Exception: Truth windows shall be permitted where a fire-resistance rating is not required. Weather-exposed truth windows shall be fitted with a weather-tight cover. Interior truth windows in Climate Zones 5, 6, 7, 8 and Marine 4 shall be fitted with an air-tight cover.

AS104.3 Vapor retarders. Class I and II vapor retarders shall not be used on a strawbale wall, nor shall any other material be used that has a vapor permeance rating of less than 3.5 perms, except as permitted or required elsewhere in this appendix.
AS104.4.3.1 General. *Clay plaster* shall be any plaster having a clay or *clay subsoil* binder. Such plaster shall contain sufficient clay to fully bind the plaster, sand or other inert granular material *aggregate*, and shall be permitted to contain reinforcing fibers. Acceptable reinforcing fibers include chopped straw, sisal and animal hair.

AS104.4.3.2 Clay subsoil requirements. The suitability of *clay subsoil* shall be determined in accordance with the Figure 2 Ribbon Test or—and the Figure 3 Ball Test in the appendix of ASTM E2392/E2392M.

AS104.4.6.1 General. *Lime plaster* is any plaster with a binder that is composed of calcium hydroxide (CaOH) including Type N or S hydrated lime, hydraulic lime, natural hydraulic lime or slaked quicklime. Hydrated lime shall comply with ASTM C206. Hydraulic lime shall comply with ASTM C1707. Natural hydraulic lime shall comply with ASTM C141 and EN 459. Quicklime shall comply with ASTM C5.

Revise as follows:

AS104.4.6.3 On structural walls. Lime *plaster on strawbale* structural walls in accordance with Table AS106.12 or Table AS106.13(1) shall use a binder of hydraulic or natural hydraulic lime.

Add new text as follows:

AS104.4.7 Clay-lime plaster. Clay-lime plaster shall be composed of refined *clay or clay subsoil*, sand, and lime, and shall be permitted to contain reinforcing fibers.

AS104.4.8 Cement-lime plaster. Cement-lime plaster shall be *plaster mixes CL, F or FL*, as described in ASTM C926.

AS104.4.8 Cement plaster. Cement *plaster* shall conform to ASTM/C926 and shall comply with Sections R703.7.4 and R703.7.5, except that the amount of lime in plaster coats shall be not less than 1 part lime to 6-4 parts cement to allow a minimum acceptable vapor permeability. The combined thickness of *plaster* coats shall be not more than 1 1/2 inches (38 mm) thick.

Revise as follows:

AS105.3 Sill plates. Sill plates shall be installed in accordance with Figure AS105.1(1) or AS105.1(2). Sill plates shall support and be flush with each face of the *straw bales* above and shall be of naturally durable or preservative-treated wood where required by this code. Sill plates shall be not less than nominal 2 inches by 4 inches (51 mm by 102 mm) with anchoring complying with Section R403.1.6 and the additional requirements of Tables Table AS105.4 and AS106.6(1), where applicable. where applicable and Sections AS106.13.2 and AS106.13.3 for strawbale braced wall panels.

AS105.4.1 Determination of out-of-plane loading. Out-of-plane loading for the use of Table AS105.4 shall be in terms of the ultimate design wind speed and seismic design category as determined in accordance with Sections R301.2.1 and R301.2.2. An engineered design in accordance with Section R301.2.1 shall be required where the building is located in a Special Wind Region or a Wind Design Required location in accordance with Figure R301.2(5).

Revise as follows:

</tbody>
</table>
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s.

N/A = Not Applicable

a. Finishes applied to both sides of stacked bales. Where different finishes are used on opposite sides of a wall, the more restrictive requirements shall apply.

b. $H =$ Stacked bale height in feet (mm) between sill plate and top plate or other approved horizontal restraint, or the horizontal distance in feet (mm) between approved vertical restraints. For load-bearing walls, $H$ refers to vertical height only.

c. $T =$ Bale thickness in feet (mm).

d. Plaster reinforcement shall be any mesh allowed in Table AS106.16 for the matching plaster type, and with staple spacing in accordance with this table. Mesh shall be installed in accordance with Section AS106.9.

e. Sill plate attachment shall be with $\frac{5}{8}$-inch anchor bolts or approved equivalent at not more than 48 inches on center where staple spacing is required to be $\leq$ 4 inches.

f. Bales shall be attached to the studs by an approved method. Horizontal framing and attachment at top and bottom of studs shall be in accordance with Section R602 or an approved alternative. Table R602.7(1) shall be used to determine the top framing member where load-bearing stud spacing exceeds 24 inches o.c.

g. $H$ is vertical height only.

AS105.6.8 Separation of wood and plaster. Where wood framing or wood sheathing occurs at the exterior face of strawbale walls, such wood surfaces shall be separated from exterior plaster with two layers of Grade D paper, No. 15 asphalt felt or other approved material in accordance with Section R703.7.3, extending not less than 1 inch (25 mm) past the edges of the framing member.

Exceptions:

1. Where the wood is preservative treated or naturally durable and is not greater than $1\frac{1}{2}$ inches (38 mm) in width.

2. Clay plaster shall not be required to be separated from untreated wood that is not greater than $1\frac{1}{2}$ inches (38 mm) in width.

AS106.2 Building limitations and requirements for use of strawbale structural walls. Buildings using strawbale structural walls shall be subject to the following limitations and requirements:

1. Number of stories: Not more than one, except that two stories shall be allowed with an approved engineered design.

2. Building height: Not more than 25 feet (7620 mm), except that greater heights shall be allowed with an approved engineered design.

3. Wall height: In accordance with Table AS105.4, AS106.13(2) or AS106.13(3) as applicable, whichever is most restrictive.

4. Braced wall panel lengths: The greater of the values determined in accordance with Tables AS106.13(2) and AS106.13(3) for buildings using strawbale braced wall panels, or in accordance with Item 4 of Section AS105.2 for buildings with load-bearing strawbale walls that do not use strawbale braced wall panels.
AS106.4 Foundations. Foundations for plastered strawbale walls shall be in accordance with Chapter 4, and Figure AS105.1(1) or Figure AS105.1(2) - or an approved engineered design.

AS106.5 Configuration - Orientation and configuration of bales. Bales in strawbale structural walls shall be laid flat or on-edge and in a running bond or stack bond, except that bales in structural walls with unreinforced plasters shall be laid in a running bond only.

AS106.8 Plaster and membranes - membranes on structural walls. Strawbale structural walls shall not have a membrane between straw and plaster, or shall have attachment through the bale wall from one plaster skin to the other in accordance with an approved engineered design.

AS106.9 Mesh. Mesh in plasters on strawbale structural walls, and where required by Table AS105.4, and where used to resist wind uplift in accordance with Section AS106.14, shall be installed in accordance with Sections AS106.9.1 through AS106.9.4.

AS106.9.1 Mesh laps. Mesh required by Table AS105.4 or AS106.12 shall be installed with not less than 4-inch (102 mm) laps. Mesh required by Table AS106.13(1) or in walls designed to resist wind uplift of more than 100 plf (1459 N/m) in accordance with Section AS106.14, shall run continuous vertically from sill plate to the top plate or roof-bearing element, or shall lap not less than 8 inches (203 mm). Horizontal laps in such mesh shall be not less than 4 inches (102 mm).

</table>

For SI: 1 inch = 25.4mm, 1 pound per foot = 14.5939 N/m.

a. Plasters shall conform to Sections AS104.4.3 through AS104.4.8, AS106.7 and AS106.10.
b. Any metal mesh allowed by this appendix and installed in accordance with Section AS106.9.
c. In accordance with Section AS106.9.2, except as required to transfer roof loads to the plaster skins in accordance with Section AS106.11.
d. For walls with a different plaster on each side, the lower value shall be used. For walls with plaster on only one side, half of the tabular value shall be used.
e. Shall use hydraulic or natural hydraulic lime.

AS106.12.3.1 Roof-bearing assembly spanning openings. Roof-bearing assemblies that span openings in strawbale walls shall comply with the following at each opening:

1. Lumber on each side of the assembly shall be of the dimensions and quantity required to span each opening in accordance with Table R602.7(1).
2. The required lumber in the assembly shall be supported at each side of the opening by the
number of jack studs required by Table R602.7(1), or shall shall extend beyond the opening on both sides a distance, D, using the following formula equation:

\[ D = S \times \frac{R}{2/(1-R)} \]  

(Equation AS-1)

where:

\[ D \] = Minimum distance (in feet) for required spanning lumber to extend beyond the opening

\[ S \] = Span (in feet)

\[ R = \frac{B_L}{B_C} \]

\[ B_L \] = Design load on the wall (in pounds per lineal foot) in accordance with Sections R301.4 and R301.6

\[ B_C \] = Allowable bearing capacity of the wall in accordance with Table AS106.12

**AS106.13 Braced wall panels.** Plastered strawbale walls used as braced wall panels for one-story buildings shall be in accordance with Section R602.10 and Tables AS106.13(1), AS106.13(2) and AS106.13(3). Wind design criteria shall be in accordance with Section R301.2.1. Seismic design criteria shall be in accordance with Section R301.2.2. An approved engineered design in accordance with Section R301.2.1 shall be required where the building is located in a Special Wind Region or Wind Design Required location in accordance with Figure R301.2(5)B.

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 pound per square foot = 0.0479 kPa.

a. Linear interpolation shall be permitted.
b. Braced wall panels shall be without openings and shall have an aspect ratio (H:L) ≤ 2:1.
c. Tabulated minimum total lengths are for braced wall lines using single braced wall panels with an aspect ratio (H:L) ≤ 2:1, or using multiple braced wall panels with aspect ratios (H:L) ≤ 1:1. For braced wall lines using two or more braced wall panels with an aspect ratio (H:L) > 1:1, the minimum total length shall be multiplied by the largest aspect ratio (H:L) of braced wall panels in that line.
d. Subject to applicable seismic adjustment factors associated with “All methods” in Table R602.10.3(4), except “Wall dead load.”
e. Strawbale braced wall panel types indicated shall comply with Sections AS106.13.1 through AS106.13.3 and Table AS106.13(1).
f. Wall bracing lengths are based on a soil site class “D.” Interpolation of bracing lengths between S\(_{ds}\) values associated with the seismic design categories is allowable where a site-specific S\(_{ds}\) value is determined in accordance with Section 1613.3 of the International Building Code.
g. Where using wall type A3, the minimum total length of braced wall panels in this column shall be...
multiplied by 1.25.

AS106.15 Post-and-beam with strawbale infill. Post-and-beam with strawbale infill systems shall be in accordance with Figure AS105.1(4) and Items 1 through 6, or be of an approved engineered design.

1. Beams shall be of the dimensions and number of members in accordance with Table R602.7(1), where the space between posts equals the span in the table.
2. Beam ends shall bear over posts not less than 1½ inches (38 mm) or be supported by a framing anchor in accordance with Table R602.7(1).
3. Discontinuous beam ends shall be spliced with a metal strap with not less than 1,000-pound (454 kg) wind or seismic load tension capacity. Where the wall line includes a braced wall pane,l the strap shall have not less than a 4,000-pound (1814 kg) capacity.
4. Each post shall equal NJ + 1 in accordance with Table R602.7(1), where the space between posts equals the span in the table.
5. Posts shall be connected to the beam by an approved means.
6. Roof and ceiling framing shall be attached to the beam in accordance with Table R602.3(1), Items 2 and 6.
7. Posts shall be supported by the sill plate of the bale wall in accordance with Sections AS105.3 or AS106.13.2, with fastening in accordance with Table R602.3(1), Item 16, or shall be supported and fastened at their base by an approved means.

Reason: This proposal does the following:
1) Removes ambiguous language and corrects errors in the 2018 Appendix S.
2) Corrects for internal consistency.
3) Adds a definition for Braced Wall Panel specific to strawbale construction, and adds a definition for Roof Bearing Assembly.
4) Expands the acceptable types of straw at the discretion of the building official, and prohibits the use of hay which is well known as inappropriate for strawbale construction.
5) Greatly clarifies which wall finishes are acceptable on strawbale walls and adds requirements for non-plaster finishes.
6) Adds clay-lime plaster as a plaster choice, which has a successful history of use on strawbale buildings.
7) Clarifies that the studs in Table AS105.4 used for out-of-plane resistance were intended to be wood studs.
8) Adds wall type A3 to the seismic braced wall panel table with an adjustment factor of 1.25, which was previously mentioned only in the Commentary.
9) Adds language regarding wind design based on input from an engineer practicing in a high wind zone. Thus the proposed explicit requirement for an approved engineered design in Special Wind Regions or Wind Design Required locations per Figure R301.2(5) of the IRC. This clarifies that strawbale construction is subject to these same requirements as other methods of construction in the IRC.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
The proposal makes corrections, improves clarity and internal consistency, but does not affect cost.
RB297-19

IRC®: FIGURE AS105.1(3), FIGURE AS105.1(4)

Proponent: Martin Hammer, representing Martin Hammer, Architect (mfhammer@pacbell.net); David Eisenberg, representing DCAT (strawnet@gmail.com); Anthony Dente, representing Verdant Structural Engineers (anthony@verdantstructural.com); David Arkin, representing California Straw Building Association (info@strawbuilding.org)

2018 International Residential Code

Revise as follows:
FIGURE AS105.1(4)
TYPICAL TOP OF POST-AND-BEAM WALL WITH PLASTERED STRAWBALE INFILL

Reason: The revision and substitution of these two Figures: 1) removes ambiguous language, 2) adds
references to a section on wind uplift that was added to the 2018 Appendix S, 3) addresses comments made by a representative of the Structural Engineers Association of California (SEAOC) at the IRC hearings in 2016

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The revised and substituted Figures clarify meaning and add references to existing sections, but do not change code requirements. Therefore there is no cost impact.
2018 International Residential Code

Revise as follows:

AS107.1.1 One-hour-rated clay-plastered wall. One-hour fire-resistance-rated nonload-bearing clay plastered strawbale walls shall comply with all of the following:

1. Bales shall be laid flat or on-edge in a running bond.
2. Bales shall maintain thickness of not less than 18 inches (457 mm).
3. Bales shall have a minimum dry density of 7.25 pounds per cubic foot (120 kg/m³).
4. Gaps shall be stuffed with straw-clay.
5. Clay plaster on each side of the wall shall be not less than 1 inch (25 mm) thick and shall be composed of a mixture of 3 parts clay, 2 parts chopped straw and 6 parts sand, or an alternative approved clay plaster.
6. Plaster application shall be in accordance with Section AS104.4.3.3 for the number and thickness of coats.

AS107.1.2 Two-hour-rated cement-plastered wall. Two-hour fire-resistance-rated nonload-bearing cement-plastered strawbale walls shall comply with all of the following:

1. Bales shall be laid flat or on-edge in a running bond.
2. Bales shall maintain a thickness of not less than 14 inches (356 mm).
3. Bales shall have a minimum dry density of 7.25 pounds per cubic foot (120 kg/m³).
4. Gaps shall be stuffed with straw-clay.
5. A single section of 1/2-inch (38 mm) by 17-gage galvanized woven wire mesh shall be attached to wood members with 1/2-inch (38 mm) staples at 6 inches (152 mm) on center. 9 gage U-pins with not less than 8-inch (203 mm) legs shall be installed at 18 inches (457 mm) on center to fasten the mesh to the bales.
6. Cement plaster on each side of the wall shall be not less than 1 inch (25 mm) thick.
7. Plaster application shall be in accordance with Section AS104.4.8 for the number and thickness of coats.

Reason: This proposed change clarifies that the density of the straw bales in the two fire-resistance rated wall assemblies as tested was not dry density and therefore the density number was adjusted accordingly. The change to the minimum density numbers for both the tested wall assemblies are based on our research revisiting some inconsistencies between our notes and information when the test panels were constructed at the ETL Semko Laboratory in Elmendorf, Texas and the descriptions of the bales and density in the test reports for the two walls. The two wall panels were constructed using the same batch of straw bales, which were all made by the same baler, thus they were all the same dimensions in height and width, though varying slightly in length. The bales all measured 18” x 14” x approximately 36.”

The test reports however indicated that two different bale dimensions – 18”x14”x36” for the earth plastered wall panel and 18”x15”x36” for the cement/lime plastered wall panel. Two string bales are typically 18”x14”x36” and our notes and drawings indicated the bales were 14” high. We know that bales are not easy to accurately
measure because some straw tends to stick up above the solidly compressed mass of straw within the strings. We had requested that the test reports be corrected but that ultimately was not done.

The procedure at the lab, which took place once the bales were delivered but before our crew was on site at the lab, was that the workers measured and weighed a sample of the bales and calculated the density from those measurements. They did not, however measure the moisture content of the bales at that time. Their notes indicated that the average bale density was 7.5 pounds per cubic foot. They noted the average weight of the bales was 42.3 pounds. We know that though the bales were very dry, they still contained some moisture. Having worked with straw bales for many years for construction purposes, and having measured the moisture content of the bales after the wall panels were built and plastered, we estimate that the bales conservatively contained about 10% moisture by weight. This would result in a calculated dry density of approximately 6.75 pounds per cubic foot if the bales had been 15” high and 7.25 pounds per cubic feet if the bales were 14” high.

Because there is no reasonable way to use wet density as a constant without stating exact moisture content, we have converted the density in this section to dry density and have based it on our evidence that the bales were 14” high.

The calculations for this dry density were determined using an average of 10% moisture content, an average 42.3 pounds per bale, and the average bale dimension of 18”x14”x36”. Thus 42.3 pounds per bale divided by 5.25 cu.ft. (36x14x18 = 5.25 cu.ft.) = 8.05 pcf wet density minus 10% moisture content = 7.245 pounds per cubic foot, rounded up to 7.25.
Cost Impact: The code change proposal will not increase or decrease the cost of construction.
The proposed change is a clarification that does not affect cost.

Proposal # 5661

RB298-19
APPENDIX U
Cob Construction (Monolithic Adobe)

SECTION AU101
GENERAL

AU101.1 Scope. This appendix provides prescriptive and performance-based requirements for the use of natural cob as a building material. Buildings using cob walls shall comply with this code except as otherwise stated in this appendix.

AU101.2 Intent. In addition to the intent described in Section R101.3, the purpose of this appendix is to establish minimum requirements for cob structures that provide flexibility in the application of certain provisions of the code, to permit the use of site-sourced and local materials, and innovative combinations of proven historical and modern techniques that are safe, reduce life-cycle impacts, and increase affordability.

AU101.3 Tests and empirical evidence. Tests for an alternative material, design or method of construction shall be in accordance with Section R104.11.1, and the building official shall have the authority to consider
evidence of a history of successful use in lieu of testing.

**AU101.4 Cob wall systems.** Cob wall systems include those shown in Figure AU101.4 and approved variations.

**FIGURE AU101.4 TYPICAL COB WALL**
SECTION AU102
DEFINITIONS

AU102.1 Definitions. The following words and terms shall, for the purposes of this appendix, have the meanings shown herein. Refer to Chapter 2 of the International Residential Code for general definitions.

BRACED WALL PANEL. A cob wall designed and constructed to resist in-plane shear loads through the interaction of the cob material, its reinforcing and its connections to its bond beam and foundation. The panel’s length meets the requirements for the particular wall type and contributes toward the total amount of bracing required along its braced wall line in accordance with Sections AU106.11 and R602.10.1.

BUTTRESS. A mass set at an angle to, or bonded to a wall that it strengthens or supports.

CLAY. Inorganic soil with particle sizes less than 0.00008 inch (0.002 mm) having the characteristics of high to very high dry strength and medium to high plasticity, used as the binder of other component materials in a mix of cob or of clay plaster.

CLAY SUBSOIL. Subsoil sourced directly from the earth, containing clay, sand, and silt, and not more than trace amounts of organic matter.

COB. A composite building material consisting of refined clay or clay subsoil wet-mixed with loose straw and sometimes sand. Also known as monolithic adobe.

COB CONSTRUCTION. A wall system of layers or lifts of moist cob placed to create monolithic walls, typically without formwork.

DRY JOINT. The boundary between a layer of moist cob and a previously laid and significantly drier, non-malleable layer of cob that requires wetting to achieve bonding between the layers.

FINISH. Completed combination of materials on the face of a cob wall.

LIFT. A layer of installed cob.

LOAD-BEARING WALL. A cob wall that supports more than 100 pounds per linear foot (1459 N/m) of vertical load in addition to its own weight.

MONOLITHIC ADOBE. Synonymous with cob.

NATURAL COB. Cob not containing admixtures such as Portland cement, lime, asphalt emulsion, or oil. Synonymous with unstabilized cob.

NONSTRUCTURAL WALL. Walls other than load-bearing walls or shear walls.

PLASTER. Clay, soil-cement, gypsum, lime, clay-lime, cement-lime, or cement plaster as described in Section AU104.

SHEAR WALL. A cob wall designed and constructed to resist in-plane lateral seismic and wind forces in accordance with Section AU106.11. Synonymous with braced wall panel.

STABILIZED. Cob or other earthen material containing admixtures such as Portland cement, lime, asphalt...
emulsion, or oil, that are intended to help limit water absorption, stabilize volume, increase strength, and increase durability.

**STRUCTURAL WALL.** A wall that meets the definition for a *load-bearing* wall or *shear wall*.

**STRAW.** The dry stems of cereal grains after the seed heads have been removed.

**UNSTABILIZED.** A *Cob* or other earthen material that does not contain admixtures such as Portland cement, lime, asphalt emulsion, or oil.

### SECTION AU103
**MATERIALS, MIXING, AND INSTALLATION**

**AU103.1 Clay subsoil.** *Clay subsoil* for a *cob* mix shall be acceptable if the mix it produces meets the requirements of Section AU103.4.

**AU103.2 Sand.** Sand or other aggregates such as, but not limited to, gravel, pumice and lava rock, when added to *cob* mixes, shall yield a mix that meets the requirements of Section AU103.4.

**AU103.3 Straw.** *Straw* for *cob* mixes shall be from wheat, rice, rye, barley or oat, or similar reinforcing fibers with similar performance. Before mixing, the straw or other reinforcing fibers shall be dry to the touch and free of visible decay.

**AU103.4 Mix proportions.** *Cob* mixes shall be of any proportion of refined *clay* or *clay subsoil*, added sand (if any) and straw that produces a dried mix that passes the shrinkage test in accordance with Section AU103.4.1, complies with the compressive strength requirements of Section AU106.6 and complies with the modulus of rupture requirements of Section AU106.7.

**AU103.4.1 Shrinkage test for cob mixes.** Each proposed *cob* mix of different mix proportions shall be placed moist to completely fill a 24-inch by 3 1/2-inch by 3 1/2-inch (610 mm by 89 mm by 89 mm) wooden form on a plastic or paper slip sheet and dried to ambient moisture conditions, or oven dried. The total shrinkage of the length shall not exceed 1 inch (25 mm), as measured from the dried edges of the material to the insides of the form. Cracks in the sample > 1/16 inch (1.5 mm) shall first be closed manually. The shrinkage test shall be shown to the building official for approval before placement of the *cob* mix onto walls.

**AU103.5 Mixing.** The *clay subsoil*, sand and straw for *cob* shall be thoroughly mixed by manual or mechanical means with water sufficient to produce a mix of a plastic consistency capable of bonding of successively placed layers or *lifts*.

**AU103.6 Installation.** *Cob* shall be installed on the wall in *lifts* of a height that supports itself with minimal slumping.

**AU103.7 Dry joints.** Each layer of cob shall be prevented from drying until the next layer is installed, to ensure bonding of successive layers. The top of each layer shall be kept moist and malleable with one or more of the following methods:

1. Covering with a material that prevents loss of or holds moisture.
2. Covering with a material that shades it from direct sun, or
3. Wetting.

When dry joints are unavoidable, the previous layer shall be wetted prior to application of the next layer.

**AU103.8 Drying holes.** Where holes to facilitate drying are used, such holes shall be of any depth and not
exceeding 3/4-inch (19 mm) in diameter on the face of cob walls. Drying holes shall not be spaced closer than ten hole-diameters. Drying holes shall not be placed in braced wall panels. The design load on load-bearing walls with drying holes shall not exceed 90% of the allowable bearing capacity as determined in accordance with Section AU106.8. Drying holes shall be filled with cob before final inspection.

AU103.9 Adding roof loads to walls. Roof and ceiling loads shall not be added until walls are sufficiently dry to support them without compressing.

SECTION AU104
FINISHES

AU104.1 General. Cob walls shall not require a finish, except as required by Section AU104.2. Finishes applied to cob walls shall be plasters in accordance with Section AU104.4, non-plaster exterior wall coverings in accordance with Section R703 or other finish systems in accordance with the following:

1. Specifications and details of the finish system’s means of attachment to the wall or its independent support and means of draining or evaporating water that penetrates the exterior finish shall be provided.
2. The vapor permeance of the combination of finish materials shall be 5 perms or greater to allow the transpiration of water vapor from the wall.
3. Finish systems with weights >10 and ≤ 20 pounds per square foot (> 48.9 and ≤ 97.8 kg/m²) of wall shall require that the minimum total length of braced wall panels in Table AU106.11(3) be multiplied by a factor of 1.2.
4. Finish systems with weights > 20 pounds per square foot (> 97.8 kg/m²) of wall area shall require an engineered design.

AU104.2 Where required. Cob walls exposed to rain due to local climate, building design and wall orientation shall be finished or clad to provide protection from excessive erosion.

AU104.3 Vapor retarders. Class I and II vapor retarders shall not be used on cob walls, except at cob walls surrounding showers or as required or addressed elsewhere in this appendix.

AU104.4 Plaster. Plaster applied to cob walls shall be any type described in this section. Plaster thickness shall not exceed 3 inches (76 mm) on each face except where an approved engineered design is provided.

AU104.4.1 Plaster and membranes. Plaster shall be applied directly to cob walls to facilitate transpiration of moisture from the walls and to secure a mechanical bond between the plaster and the cob. A membrane shall not be located between the cob wall and the plaster.

AU104.4.2 Plaster lath. The surface of cob walls shall be permitted to function as lath for plaster, with no other lath required. Metal, plastic, and natural fiber lath shall be permitted to be used to limit plaster cracking or increase the plaster bond to the wall, or to bridge dissimilar materials.

AU104.4.3 Clay plaster. Clay plaster shall comply with Sections AU104.4.3.1 and AU104.4.3.2.

AU104.4.3.1 General. Clay plaster shall be any plaster having a clay or clay subsoil binder. Such plaster shall contain sufficient clay to fully bind the sand or other aggregate and any reinforcing fibers. Reinforcing fibers shall be chopped straw, sisal, hemp, animal hair or other similar approved fibers.

AU104.4.3.2 Clay subsoil requirements. The suitability of clay subsoil shall be determined in accordance with the Figure 2 Ribbon Test and the Figure 3 Ball Test in the appendix of ASTM E2392/E2392M.

AU104.4.4 Soil-cement plaster. Soil-cement plaster shall be composed of clay subsoil, sand, not more than 7 percent Portland cement by volume and, where provided, reinforcing fibers.
AU104.4.5 Gypsum plaster. Gypsum plaster shall comply with Section R702.2.1 and shall be limited to interior use.

AU104.4.6 Lime plaster. Lime plaster is any plaster with a binder composed of calcium hydroxide including Type N or S hydrated lime, hydraulic lime, natural hydraulic lime or slaked quicklime. Hydrated lime shall comply with ASTM C206. Hydraulic lime shall comply with ASTM C1707. Natural hydraulic lime shall comply with ASTM C141 and EN 459. Quicklime shall comply with ASTM C5.

AU104.4.7 Clay-lime plaster. Clay-lime plaster shall be composed of refined clay or clay subsoil, sand, lime and, where provided, reinforcing fibers.

AU104.4.8 Cement-lime plaster. Cement-lime plaster shall be plaster mix types CL, F or FL, as described in ASTM C926.

AU104.4.9 Cement plaster. Cement plaster shall have not less than 1 part lime to 4 parts cement and be not thicker than 1-1/2 inches (38 mm), to ensure minimum acceptable vapor permeability.

SECTION AU105
COB WALLS—GENERAL

AU105.1 General. Cob walls shall be designed and constructed in accordance with this section and Figure AU101.4 or an approved alternative design. In addition to the general requirements for cob walls in this section, cob structural walls shall comply with Section AU106.

AU105.2 Building limitations and requirements for cob wall construction. Cob walls shall be subject to the following limitations and requirements:

1. Number of stories: not more than one.
2. Building height: not more than 25 feet (7620 mm).
3. Seismic design categories: limited to use in Seismic Design Categories A, B and C, except where an approved engineered design is provided.
4. Wall height: in accordance with Table AU105.4, and with Table AU106.11(1) for braced wall panels.
5. Wall thickness, excluding finish, shall be not less than 10 inches, not greater than 24 inches at the top two-thirds, not limited at the bottom third and, for structural walls, shall comply with Section AU106.2(2). Wall taper is permitted in accordance with Section AU106.5(1).
6. Interior cob walls shall require an approved engineered design that accounts for the seismic load of the interior cob walls, except in Seismic Design Category A for walls with a height to thickness ratio ≤ to 6.

AU105.3 Out-of-plane resistance methods and unrestrained wall height limits. Cob walls shall employ a method of out-of-plane load resistance in accordance with Table AU105.3, and comply with its associated height limits and requirements.

AU105.3.1 Determination of out-of-plane loading. Out-of-plane loading for the use of Table AU105.3 shall be in accordance with the ultimate design wind speed and seismic design category requirements of Sections R301.2.1 and R301.2.2 respectively. An approved engineered design shall be required where the building is located in a Special Wind Region or a Wind Design Required location in accordance with Figure R301.2(5)B.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s.

N/A = Not Applicable

a. See Table AU106.11(1) for reinforcing and anchorage specifications for wall types A, B, C, D and E.

b. $H =$ height of the cob portion of the wall only. See Figure AU101.4. The maximum $H$ is the absolute limit or the limit based on wall thickness, whichever is more restrictive.

c. Bond beams or other horizontal restraints are capable of separating a wall into more than one unrestrained wall height with an approved engineered design.

d. $T = $ Cob wall thickness (in feet) at its minimum, without plaster.

e. 5/8-inch threaded rod anchors at prescribed spacing with 12" embedment in cob, full embedment in concrete bond beams or full penetration in wood bond beam with a nut and washer.

f. Attach rafters to bond beam with 4-inch by 3-inch by 3-inch by 18 gage tension tie angles at prescribed spacing. See Figure R608.9(9). Where rafters are attached to tension ties shall, roof sheathing shall be edge nailed.
g. All walls shall be tested for compressive strength in accordance with Section AU106.6.

h. For curved walls with an arc length:radius ratio of 1.5:1 or greater, the H/T factor shall be increased by 1, and the absolute height limit by 1 foot.

i. Wall type requires a modulus of rupture test in accordance with Section AU106.7.

j. See wall type A in Table AU106.11(1) for top anchor requirements.

AU105.3.2 Bond beams for nonstructural walls. Nonstructural cob walls shall be provided with a bond beam at the top of the wall that complies with Section AU106.9, except for requirements relating to roof and/or ceiling loads or braced wall panels.

AU105.3.3 Lintels in nonstructural walls. Door, window, and other openings in nonstructural cob walls shall require a lintel in accordance with Section AU106.10, except for requirements relating to roof and/or ceiling loads or braced wall panels.

AU105.3.4 Reinforcing at wall openings. Reinforcing shall be installed at window, door, and similar wall openings and penetrations greater than 2 feet (610 mm) in width in accordance with this section. Surface voids deeper than 25 percent of the wall thickness shall be considered an opening.

AU105.3.4.1 Opening size limit. Openings shall not exceed 6 feet (1829 mm) in width, and the height of the cob wall below openings shall not exceed 6 feet (1829 mm) above the top of the foundation.

AU105.3.4.2 Horizontal reinforcing. 2-inch by 2-inch (51 mm by 51 mm) 14 gage galvanized steel mesh shall be embedded 4 inches (102 mm) in the cob above the rough opening and below the rough opening for windows, and shall extend 12 inches (305 mm) beyond the sides of the opening. Walls below rough window openings greater than 4 foot 6 inches (1372 mm) in height shall be provided with additional horizontal reinforcing at mid-height.

AU105.3.4.3 Vertical reinforcing. Full-height 5/8-inch (16 mm) threaded rod shall be installed 4 inches (102 mm) from each side of the opening, centered in the thickness of the cob wall. The threaded rods shall be embedded 7 inches (178 mm) in the foundation, and 4 inches (102 mm) in concrete bond beams or shall penetrate through wood bond beams and be secured with a nut and washer. The threaded rods shall be embedded in concrete lintels, or pass through a drilled hole in wood lintels.

AU105.3.5 Minimum length of cob walls. Sections of cob walls between openings shall be not less than 2 foot 6 inches (762 mm) in length. Wall sections less than 4 feet (1219 mm) and not less than 2 foot 6 inches (762 mm) in length shall contain vertical reinforcing in accordance with Section AU105.3.4.3

AU105.4 Moisture control. Cob walls shall be protected from moisture intrusion and damage in accordance with Sections AU105.4.1 through AU105.4.5.

AU105.4.1 Water-resistant barriers and vapor permeance. Cob walls shall be constructed without a membrane barrier between the cob wall and plaster to facilitate transpiration of water vapor from the wall, and to secure a mechanical bond between the cob and plaster, except as otherwise required elsewhere in this appendix. Where a water-resistant barrier is placed behind an exterior finish, it shall be considered part of the finish system and shall comply with Section AU104.1(2) for the combined vapor permeance rating.

AU105.4.2 Horizontal surfaces. Cob walls and other cob elements shall be provided with a water-resistant barrier at weather-exposed horizontal surfaces. The water-resistant barrier shall be of a material and installation that will prevent erosion and prevent water from entering the wall system. Horizontal surfaces, including exterior window sills, sills at exterior niches, and exterior buttresses, shall be sloped not less than 1 unit vertical in 12
units horizontal to drain away from cob walls or other cob elements.

AU105.4.3 Separation of cob and foundation. A liquid-applied or bituminous Class II vapor retarder shall be installed between cob and supporting concrete or masonry.

Exception: Where local climate, site conditions and foundation design limit ground moisture migration into the base of the cob wall, including but not limited to the use of a moisture barrier or capillary break between the supporting concrete or masonry and the earth.

AU105.4.4 Separation of cob and finished grade. Cob shall be not less than 8 inches (203 mm) above finished grade.

Exception: The minimum separation shall be 4 inches (102 mm) in Dry climate zones as defined in Table N1101.7.2(1) [R302.3(1)], and shall be 2 inches (51 mm) on walls that are not weather-exposed.

AU105.4.5 Installation of windows and doors. Windows and doors shall be installed in accordance with the manufacturer’s instructions to a wooden frame of not less than nominal 2x4 (51 mm by 102 mm) wood members anchored into the cob wall with 16d galvanized nails half-driven at a maximum 6-inch (152 mm) spacing, with the protruding half embedded in the cob. The wood frame shall be embedded not less than 1-1/2 inches (38 mm) in the cob and shall be set in from each face of the wall not less than 3 inches (76 mm). Alternative window and door installation methods shall be capable of resisting the wind loads in Table R301.2(2). Windows and doors in cob walls shall be installed so as to mitigate the passage of air or moisture into or through the wall system. Window sills shall comply with Section AU105.4.2.

AU105.5 Inspections. The building official shall inspect the following aspects of cob construction in addition to the required tests of, and accordance with Section R109.1:

1. Anchors and vertical and horizontal reinforcing in cob walls, where required in accordance with Tables AU105.2 and AU106.11(1) and Sections AU105.3.4 and AU105.3.5.
2. Reinforcing in any concrete bond beams or lintels, in accordance with Sections AU106.9.2 and Table AU106.10.

SECTION AU106
COB WALLS—STRUCTURAL

AU106.1 General. Cob structural walls shall be in accordance with the prescriptive provisions of this section. Designs or portions of designs not complying with this section shall require an approved engineered design.

AU106.2 Requirements for cob structural walls. In addition to the requirements of Section AU105.2, cob structural walls shall be subject to the following:

1. Wall height: shall be in accordance with Table AU105.3 for load-bearing cob walls or AU106.11(1) for cob braced wall panels, as applicable and most restrictive.
2. Wall thickness: shall be in accordance with Section AU105.2(5) and Section AU106.8.1 for load-bearing cob walls or AU106.11(1) for cob braced wall panels, as applicable and most restrictive.
3. Braced wall panel lengths: for buildings using cob braced wall panels, the greater of the values determined in accordance with Tables AU106.11(2) for wind loads and AU106.11(3) for seismic loads shall be used.

AU106.3 Loads and other limitations. Live and dead loads and other limitations shall be in accordance with Section R301, except that the dead load for cob walls shall be determined with the following equation:

\[ CW_{DL} = (H \times T_{avg} \times D) \] (Equation AU-1)

where:

\[ CW_{DL} = \text{Cob wall dead load (in pounds per lineal foot of wall)} \]
**H** = Height of cob portion of wall (in feet)

**T_avg** = Average thickness of wall (in feet)

**D** = Density of cob = 110 (in pcf), unless a lesser value at equilibrium moisture content is demonstrated to the building official

**AU106.4 Foundations.** Foundations for cob walls shall be in accordance with Chapter 4. The width of foundations for cob walls shall be not less than the width of the cob at its base, excluding finish.

**AU106.5 Wall taper, straightness and surface voids for cob walls.** Cob walls shall be in accordance with the following:

1. Cob structural and nonstructural walls shall be vertical, or shall taper from bottom to top with the wall thickness in accordance with Section AU105.2(5) and the wall height in accordance with AU105.2(4).
2. Cob structural and nonstructural walls shall be straight or curved. Curved braced wall panels shall be in accordance with Sections AU106.11.2 and AU106.11.3.
3. Niches and other surface voids in load-bearing walls are limited to 12 inches (305 mm) in width and height and 25 percent of the wall thickness, and shall be located in the top two-thirds of the wall. Surface voids that exceed these limits shall be considered wall openings, and shall receive a lintel in accordance with Section AU106.10 and be reinforced in accordance with Section AU105.3.4. Surface voids are prohibited in braced wall panels.

**AU106.6 Compressive strength of cob structural and nonstructural walls.** All cob walls shall have a minimum compressive strength of 60 psi (414 kPa). Cob in walls used as braced wall panels shall have a minimum compressive strength of 85 psi (586 kPa).

**AU106.6.1 Demonstration of compressive strength.** The compressive strength of the cob mix to be used in structural walls and nonstructural walls as required in Section AU106.6 shall be demonstrated to the building official before the placement of cob onto walls, with compressive strength tests and an associated report by an approved laboratory or with an approved on-site test as follows:

1. Five samples of the proposed cob mix shall be placed moist to completely fill a 4-inch by 4-inch by 4-inch (102 mm by 102 mm by 102 mm) form and dried to ambient moisture conditions. Samples shall not be oven dried. Any opposite faces shall be faced with plaster of Paris if needed to achieve smooth, parallel faces, after which the sample shall reach ambient moisture conditions before testing. The horizontal cross-section of the dried sample as tested, and the maximum applied load at failure shall be used to calculate the sample’s compressive strength. The fourth lowest value shall be used to determine the mix’s compressive strength.

**AU106.7 Modulus of rupture of cob structural walls.** Cob in walls used as braced wall panels shall have a minimum modulus of rupture of 50 psi (345 kPa).

**AU106.7.1 Demonstration of modulus of rupture.** The modulus of rupture of cob used in structural walls as required in Section AU106.7 shall be demonstrated to the building official before the placement of cob onto walls, with modulus of rupture tests and an associated report by an approved laboratory or with an approved on-site test as follows:

1. Five samples of the proposed cob mix shall be placed moist to completely fill a 6-inch by 6-inch by 12-inch (152 mm by 152 mm by 305 mm) form and dried to indoor ambient moisture conditions. Samples shall not be oven dried. Each sample shall be tested with the 12-inch (305 mm) dimension horizontal. The fourth lowest value shall be used to determine if the mix’s meets the minimum required modulus of rupture.

**AU106.8 Bearing capacity.** The allowable bearing capacity for cob load-bearing walls supporting vertical roof
and/or ceiling loads imposed in accordance with Section R301 shall be determined with the following equation:

\[ BC = \left( C \times T_{\text{min}} \right)/3 - ( H \times T_{\text{avg}} \times D ) \] (Equation AU-2)

where:

\[ BC = \text{Allowable bearing capacity of wall (in pounds per lineal foot of wall)} \]

\[ C = \text{Compressive strength (in psi) as determined in accordance with Section AU106.6} \]

\[ T_{\text{min}} = \text{Thickness of wall (in feet) at its minimum} \]

\[ H = \text{Height of cob portion of wall (in feet)} \]

\[ T_{\text{avg}} = \text{Average thickness of wall (in feet)} \]

\[ D = \text{Density of cob = 110 (in pcf), unless a lesser value at equilibrium moisture content is demonstrated} \]

**AU106.8.1 Support of uniform loads.** Uniform roof and/or ceiling loads shall be supported by cob load-bearing walls not exceeding their allowable bearing capacity, as demonstrated in accordance with the following equation:

\[ BL \leq BC \] (Equation AU-3)

where:

\[ BL = \text{Design load on the wall (in pounds per lineal foot) determined in accordance with Sections R301.4 and R301.6} \]

\[ BC = \text{Allowable bearing capacity of wall (in pounds per lineal foot of wall) determined in accordance with Section AU106.8} \]

**AU106.8.2 Support of concentrated loads.** Concentrated roof and/or ceiling loads shall be distributed by structural elements capable of distributing the loads to the cob load-bearing wall and within its allowable bearing capacity as determined in accordance with Section AU106.8. Concentrated loads over lintels or over bond beams spanning openings shall require an approved engineered design.

**AU106.9 Bond beams.** Cob structural walls shall require a bond beam at the top of the wall in accordance with Sections AU106.9.1, AU106.9.2 or AU106.9.3, and shall be anchored to the cob below in accordance with Tables AU105.3, AU106.11(1) and AU106.12 as applicable and most restrictive. Bond beams spanning openings shall be in accordance with Section AU106.9.4.

**AU106.9.1 Wood bond beams.** Wood bond beams shall be not less than nominal 4 inches high by 8 inches wide and shall comply with Sections AU106.9.1.1 through AU106.9.1.3.

**AU106.9.1.1 Wood species and grade.** Wood bond beams shall be of a species with an extreme fiber in bending \( (F_b) \) of not less than 850 psi (5.9 MPa), a modulus of elasticity \( (E) \) of not less than 1,300,000 psi (8964 MPa), and of No. 2 grade or better. Composite lumber bond beams shall have an extreme fiber in bending \( (F_b) \) of not less than 850 psi (5.9 MPa), and a modulus of elasticity \( (E) \) of not less than 1,300,000 psi (8964 MPa).

**AU106.9.1.2 Discontinuity.** Discontinuous wood bond beams shall be spliced on top with a metal strap with not less than the allowable wind or seismic load tension capacity in accordance with the following, whichever is more restrictive:
1. For seismic design categories: A: 2500 pounds (11 kN), B: 4500 pounds (20 kN), C: 6000 pounds (26.7 kN).

2. For braced wall line lengths, when wind governs: 10 feet: 2500 pounds (11 kN). 20 feet: 3400 pounds (15.1 kN). 30 feet: 5000 pounds (22.2 kN).

AU106.9.1.3 Corners and curved walls. Wood bond beams at corners and discontinuities atop curved walls shall be connected across their exterior faces with a metal strap with a capacity of not less than that determined in accordance with Section AU106.9.2.

AU106.9.2 Concrete bond beams. Concrete bond beams shall be not less than 6 inches (152 mm) high by 8 inches (305 mm) wide. Concrete bond beams shall be reinforced with two # 4 bars, 2 inches (51 mm) clear from the bottom and 2 inches (51 mm) clear from the sides. Lap splices shall comply with Table R608.5.4(1). Reinforcing at corners shall be in accordance with the horizontal reinforcing requirements in Section R608.6.4. The concrete shall have a compressive strength of not less than 2500 psi (17.2 MPa) at 28 days.

AU106.9.3 Other bond beams. Bond beams of other materials, including earthen materials, require an approved engineered design.

AU106.9.4 Bond beams spanning openings. Bond beams that support uniform roof and/or ceiling loads and span openings in cob walls shall be in accordance with Table AU106.10. Bond beams shall be continuous across the opening and not less than 1 foot (305 mm) beyond each side of the opening.

AU106.9.5 Connection of roof framing to bond beams. Roof and ceiling framing shall be attached to bond beams in accordance with Table R602.3(1), Items 2, 6, 30, 31, and 32. Tension ties shall be provided in accordance with Figure R608.9(9) and Footnote f of Table AU105.3. 10d toe nails at 6 inches (152 mm) on center shall be provided from the rim blocking to top plate for the entirety of braced wall lines, instead of the 43 mil strap shown in Figure R608.9(9). A nominal 2-inch by 6-inch (51 mm by 152 mm) wood plate shall be installed on concrete bond beams with 5/8-inch (16 mm) diameter anchor bolts with 5-inch (127 mm) embedment at 2 feet (610 mm) on center to allow the required fastening of roof and ceiling framing, including tension ties and toe nailing of rim blocking.

AU106.9.6 Bond beams at gable and shed roof end walls. Bond beams at end walls of buildings with gable or shed roofs shall comply with the following:

1. End walls shall not exceed 20 feet (6096 mm) in length.
2. Shall be continuous and straight for the entire wall line.
3. Wood bond beams when used shall comply with the following:

3.1. Not less than nominal 4x8 (102 mm by 203 mm) when wind design governs in accordance with Tables AU106.11(2) and AU106.11(3), and for wall lengths ≤ 20 feet (6096 mm) in Seismic Design Category A, and for wall lengths ≤ 10 feet (3048 mm) in Seismic Design Categories B and C.

3.2. Not less than nominal 4x10 (102 mm by 254 mm) for wall lengths ≤ 20 feet (6096 mm) in Seismic Design Category B.

3.3. Not less than nominal 6x12 (152 mm by 305 mm) or 4x16 (102 mm by 406 mm) for wall lengths ≤ 20 feet (6096 mm) in Seismic Design Category C.

4. Concrete bond beams when used shall be in accordance with Section AU106.9.2 in Seismic Design Categories A, B, and C and for ultimate design wind speeds ≤ 140 mph (63.6 m/s).

5. Walls between the bond beam and roof shall be of wood-framed construction in accordance with Section R602.

AU106.10 Lintels. Door, window, and other openings in load-bearing cob walls shall be provided with a lintel of
wood or concrete in accordance with Table AU106.10.

### TABLE AU106.10 LINTELS AND BOND BEAMS SPANNING OPENINGS

**• GROUND SNOW LOAD ≤ 30 PSF**

**WOOD:**
- \( F_b \geq 850 \text{ PSI} \)
- \( E \geq 1,300,000 \text{ PSI} \)
- NO. 2 GRADE OR BETTER
- ORIENTED FLAT
- 1 PIECE OR 2 EQUAL-WIDTH PIECES
- EXTEND 1 FT BEYOND OPENING SIDES

**CONCRETE:**
- 2500 PSI COMpressive STRENGTH
- HEIGHT = 6”
- EXTEND 1 FT BEYOND OPENING SIDES
- REINFORCEMENT: 2 - #4 BARS
- 2” CLEAR FROM BOTTOM
- 2” CLEAR FROM SIDES

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm

NP = Not Permitted

a. Concrete bond beams spanning openings, and lintels greater than 16 inches in width, shall have an additional #4 bar in the center of their width.

AU106.11 Cob braced wall panels. Cob braced wall panels shall be in accordance with Section R602.10 and Tables AU106.11(1), AU106.11(2) and AU106.11(3A), AU106.11(3B) and AU106.11(3C). Wind design criteria shall be in accordance with Section R301.2.1. Seismic design criteria shall be in accordance with Section R301.2.2. An approved engineered design shall be required in accordance with Section R301.2.1 where the building is located in a Special Wind Region or a Wind Design Required location in accordance with Figure R301.2(5B).

AU106.11.1 Non-orthogonal braced wall panels. Braced wall panels at an angle to the orthogonal braced wall lines shall be considered to contribute to the minimum total braced wall lengths in Tables AU106.11(2) and AU106.11(3) as follows:

1. A braced wall panel not more than 45 degrees and greater than 30 degrees to an adjacent orthogonal braced wall line shall contribute 50% of its length to that line.
2. A braced wall panel not more than 30 degrees to an orthogonal braced wall line shall contribute 65 percent of its length to that line.
3. A braced wall panel greater than 45 degrees and not more than 60 degrees to an orthogonal braced wall line shall contribute 35 percent of its length to that line.
4. The angle of a curved braced wall panel to a braced wall line shall be determined with the chord of that section of wall, connecting the end points of the arc at the center of the wall.

AU106.11.2 Braced wall lines for buildings with curved walls. Buildings with curved cob walls shall contain two braced wall lines in two orthogonal directions. The spacing of the braced wall lines for wind design in Table AU106.11(2) and the spacing and length of the braced wall lines for seismic design in Table AU106.11(3), shall be the maximum widths of the building in the two orthogonal directions.

AU106.11.3 Radius, thickness and length of curved braced wall panels. Cob curved braced wall panels shall have an inside radius of not less than 5 feet (1524 mm), shall be of the thickness required in Table AU106.11(1) and of the length determined in accordance with Section AU106.11. The curved wall’s length shall be considered to be the length of the arc at the center of the wall, in accordance with Figure AU106.11.3 and determined with the following equation:

\[ ARC_C = 0.0175 \times RC \times A \]  
(Equation AU-4)

where:

\[ ARC_C = \text{Length of arc at center of wall (in feet)} \]

\[ RC = \text{Radius at center of wall} = R_I + 0.5T \text{ (in feet)} \]

\[ R_I = \text{Inside radius of wall (in feet)} \]
$T =$ Thickness of wall without finish (in feet)

$A =$ Angle of extent of braced wall panel from the center of the arc (in degrees)

**a.** Braced wall panel types A, B, C, and D shall be not less than 16 inches thick. Brace wall panel type E shall be not less than 12 inches thick. All braced wall panels shall be not greater than 24 inches thick.

**b.** Not less than 8” embedment into foundation, unless otherwise stated.

**c.** Not less than 4” embedment into concrete bond beams. Full penetration through wood bond beam, secured with nut and washer.

**d.** $H$ = height of the cob portion of the wall only. See Figure AU101.4.

**e.** Maximum height shall be 8 feet when wall thickness is increased to 18”.

**f.** Galvanized mesh.

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 pound per square foot = 0.0479 kPa.

NP = Not Permitted

a. Interpolation is not permitted.

b. Braced wall panels shall be without openings.

c. Braced wall panel types A, B and E shall have an aspect ratio (H:L) ≤ 1:1. Braced wall panel types C and D shall have an aspect ratio (H:L) ≤ 2:1.

d. Subject to applicable seismic adjustment factors associated with item 5 in Table R602.10.3(4).

e. Cob braced panel types indicated shall comply with Sections AU106.11.1, AU106.11.2 and Table AU106.11(1).

f. Wall bracing lengths are based on a soil site class “D.” Interpolation of bracing lengths between Sds values associated with the seismic design categories is allowable where a site-specific Sds value is determined in accordance with Section 1613.3 of the International Building Code.

g. Openings in the braced wall line shall not be limited, except that the minimum total braced wall panel length shall be as determined by Tables AU106.11(3A) and AU106.11(2).

h. For total plaster thicknesses 3” to 6”, multiply the minimum total length of braced wall panels by 1.2.

i. Total plaster thickness > 3” is not permitted. Substitute 15/32” roof sheathing and 10d at 6” edge nailing for requirements in Table R602.3(1).

**AU106.12 Resistance to wind uplift forces.** Cob walls that resist uplift forces from the roof assembly, as determined in accordance with Section R802.11, shall be in accordance with Table AU106.12.

**TABLE AU106.12 ANCHORAGE OF BOND BEAMS FOR WIND UPLIFT**

- ANCHORS: 5/8” ALL THREAD AT 12” O.C. a, b

</tr>
</tbody>
</table>

a. For wood bond beams a maximum of 6” from bond beam ends.

b. For min. 6”x8” concrete bond beams, at 18” o.c. for wind uplift forces < 75 plf., and at 16” o.c for wind uplift forces < 100 plf.

c. Excluding finishes.

d. With 7-inch embedment in foundation, 4-inch embedment in concrete bond beam or full penetration through wood bond beam with 2”x2”x1/4” washer and nut.

**AU106.13 Post-and-beam with cob infill.** Post-and-beam with cob infill wall systems shall be in accordance with an approved engineered design.

**AU106.14 Buttresses.** Cob buttresses that are intended to provide out-of-plane wall bracing, or additional capacity for braced wall panels shall be in accordance with an approved engineered design.

**SECTION AU107**

**COB FLOORS**

**AU107.1 Cob floors.** Cob floors supported by grade shall be in accordance with an approved specification. Straw shall not be required in the material mix.

**SECTION AU108**

**FIRE RESISTANCE**

**AU108.1 Fire-resistance rating.** Cob walls shall be considered to exhibit a 1-hour fire-resistance rating in accordance with the following:

1. Wall thickness shall be 10 inches (254 mm) or greater.
2. Density shall be 70 pcf (1121 kg/m<sup>3</sup>) or greater.
3. When used as a load-bearing wall, the maximum design load shall be 1000 pounds per lineal foot (14,590 N/m) in accordance with Section AS106.8.
4. When used as a braced wall panel, the wall shall be in accordance with Section AS106.11.

**AU108.2 Clearance to fireplaces and chimneys.** Cob walls or other cob surfaces shall not require clearance to fireplaces and chimneys, except where clearance to non-combustibles is required by the manufacturer’s instructions.
THERMAL PERFORMANCE

AU109.1 Thermal characteristics. Cob walls shall be classified as mass walls in accordance with Section N1102.2.5 (R402.2.5) and shall meet the R-value requirements for mass walls in Table N1102.1.2 (R402.1.2).

AU109.2 Thermal resistance. The unit R-value for cob walls with a density of 110 pcf (1762 kg/m$^3$) shall be R-0.22 per inch of cob thickness. Walls that vary in thickness along their height or length shall use the average thickness of the wall to determine its R-value. The thermal resistance values of air films and finish materials or additional insulation shall be added to the cob wall's thermal resistance value to determine the R-value of the wall assembly.

AU109.3 Additional insulation. When insulating materials are added to the face of a cob wall, the combination of additional insulation and any associated connecting, weather-resisting, or protective materials shall comply with Section AU104.1, Items 1-4.

SECTION AU110 REFERENCED STANDARDS

- ASTM C1707—11 Standard Specification for Pozzolanic Hydraulic Lime for Structural Purposes - AU104.4.6.1
- ASTM E2392/ E2392M—10 Standard Guide for Design of Earthen Wall Building Systems - AU104.4.3.2

Reason: Cob is an earthen material mix of clay-soil, sand, straw, and water, placed onto a wall in layers to create a monolithic wall. Because the material mix and density of cob are very similar to those of adobe bricks, cob is sometimes known as “monolithic adobe.” Cob has been used for thousands of years around the world, notably in England and Northern Europe, the Middle East, West Africa, China, and the Southwestern United States. An estimated 20,000 cob homes are still inhabited in the English county of Devon alone, some dating from the 15th century. The term “cob” derives from an Old English word for “lump,” since historical structures were often constructed one handful at a time.

ICC COMMITTEE ACTION HEARINGS ::: April, 2019
Today, cob is often mixed mechanically using a tractor or mortar mixer, but the wall construction is still generally manual. Cob buildings typically feature raised impermeable foundations and extended roof eaves to protect the walls from moisture and weather. Walls are often plastered with clay, lime or gypsum plasters which protect and beautify the cob without leading to the moisture problems associated with less vapor-permeable finishes such as cement stucco on historic adobe structures.

2-Story Cob Cottage in Devon, England, Built in the 1400s

2-Story Cob House Built In 1860, Aniseed Valley, New Zealand
Since the 1990’s, there has been increasing interest in cob construction in the United States and much of the world. Like other earthen construction methods, cob can greatly reduce embodied energy and life-cycle CO2 emissions of buildings. Cob is highly recyclable, and with good design, construction and maintenance, can withstand centuries of use. The constituent materials are inexpensive compared with lumber, steel, concrete and other commonly used building materials. Cob is non-combustible and non-toxic in all stages of construction and use. Cob’s thermal mass and moisture management properties modulate interior temperature and humidity, creating healthful building.

While adobe is included in the masonry chapter of the IBC, and cob building codes or guidelines exist in England and New Zealand, there is currently no cob building code in the United States. As a result, permitting of cob buildings has been left to individual building officials on a case-by-case basis. Designers, builders and officials may be unaware of proper practices to make cob buildings safe and durable. Nevertheless, the desire to utilize cob construction continues, and promises to accelerate in response to economic and environmental pressures. These include the need for non-combustible construction systems that can withstand the increased frequency and intensity of wildfires in the western U.S. The lack of a cob building code has been an impediment to the proper and broader use of cob construction.
The proposed Cob Construction appendix for the IRC was created in response to this need. It is based on New Zealand's earthen building standards, on US codes for the closely-related earthen building systems of adobe and straw-clay, and on the experience and the testing of cob buildings over the past 25 years by architects, engineers, builders, and academics throughout the U.S. and the world. It has received review and input from over 25 experts including 4 architects and 6 civil engineers, including the architect and chair of the Committee that developed the New Zealand Standard for Earth Buildings. Much of the recent testing and research has been compiled or performed by the California-based Cob Research Institute, a non-profit organization founded in 2008 to remove legal barriers to cob construction and promote its safe use. If adopted, the proposed appendix will serve designers, builders, owners, inhabitants, and building officials alike in the design and construction of safe and durable cob buildings.

Supporting documents for the proposed Cob Construction appendix is available at: https://www.cobcode.org/cobcode-documents

**Rationale for Specific Sections of Proposed Appendix U – Cob Construction**

**GENERAL:**

Cob construction can help address the increasing need to reduce our buildings' negative impacts on the environment, including the global climate, and address the impacts of a changing climate on buildings, including increased firestorms. Like other earthen wall systems, cob is among the most fire-resistant building materials available, while also having a low environmental impact. The ability to build with site- or locally-sourced materials further reduces processing and transportation impacts as well as costs.

Though cob construction is not an industrialized building system, its centuries of continuous use in many parts of the world provide empirical evidence and guidance for good practice. This appendix gives the building official greater flexibility to consider empirical evidence and lifecycle impacts in meeting the intent of the code while not abridging health and life-safety requirements.

**DEFINITIONS:**

Cob-specific terms not found in the IRC are defined. Some terms already defined in the IRC are adjusted to give
specific meaning for cob construction. Some definitions are consistent with identical terms defined in IRC Appendix R – Light Straw Clay Construction, and Appendix S – Strawbale Construction.

**MATERIALS, MIXING AND INSTALLATION:**

The provisions for materials, mixing, and installation are based on existing codes, standards, and guidelines from the UK, New Zealand and the U.S., including ASTM E2392-10 Standard Guide for the Design of Earthen Wall Systems, as well as the experience of designers and builders of cob and earthen buildings in the U.S. and other countries.

Though the materials for cob can vary considerably, the material specifications coupled with the mix design tests for shrinkage, compressive strength and modulus of rupture ensure adequate strength and stability of the wall materials.

**FINISHES:**

Where cob walls are not substantially rain-exposed they are allowed to remain without finish. Minor erosion has proven to be acceptable on cob walls, and is a matter of maintenance, not unlike the need to periodically repaint the exterior of buildings of conventional construction. However, where cob walls are susceptible to excessive erosion or water intrusion from weather, finishes are necessary to protect the wall while ensuring that any moisture that might enter the wall is able to escape without causing harm. Thus, finishes and finish assemblies must be a minimum of 5 perms, the IRC defined threshold of vapor permeable. Class I and II vapor retarders are prohibited on cob walls except where specifically permitted or required, for example at showers.

A range of plaster types are allowed and described, specifying critical components and characteristics of the plasters, the recognized standards with which they must comply, and other necessary details for their installation. The plasters allowed in the appendix have a history of successful use on cob and other earthen wall systems.

Non-plaster finishes systems are allowed with approved specifications that ensure: adequate attachment or support, the ability to safely discharge moisture, a minimum vapor permeance rating, and compliance with stated weight limits.

**COB WALLS - GENERAL:**

General limits are given for all cob buildings, including: one story; maximum building height of 25 feet; Seismic Design Categories A, B, and C (except with an approved engineered design); wall height and wall thickness limitations; and an approved engineered design for interior cob walls that addresses their seismic lateral loads (except in Seismic Design Category A).

A method of out-of-plane resistance is required for all walls, and wall height limits are given. Bond beams are required and described for all cob walls, as are lintels over door and window openings. Reinforcing at window and door openings is required for openings wider than 2 feet. Window openings are limited to 6 feet in width and horizontal and vertical reinforcing at window and door openings is required and described. A minimum cob wall length between openings is given and reinforcing required to ensure the wall’s stability.

Moisture control requirements address potential moisture intrusion from rain or snow, or through capillary action from the ground and help ensure that moisture that might enter is not trapped. That protection includes limiting the use of membranes and barriers between the cob and plaster finishes. Limiting the use of membranes also enables a mechanical bond between the plaster and the cob.
A Class I or II vapor retarder is required between the bottom of the cob wall and the foundation to prevent ground moisture from rising into the wall, unless the particular project conditions and design eliminate this need. A minimum separation of the cob wall above finished grade is required. Protection of horizontal surfaces is required to prevent erosion and water intrusion.

Requirements for installing windows and doors are given so they are secure and prevent the passage of air or moisture through or into the wall.

In addition to inspections normally required, inspections specific to cob construction are required for the anchors connecting cob walls to the foundation and the bond beam, for required vertical or horizontal reinforcing in the walls, and for reinforcing in any concrete bond beams or lintels.

**COB WALLS - STRUCTURAL:**

Cob walls are a compression dominant wall system containing a micro-reinforcing system of straw throughout. Testing has shown this increases ductility compared to earthen materials with no straw. Cob can be reinforced with other standard reinforcing materials such as steel bar and welded wire mesh, making it akin to concrete construction in this respect. Cob wall systems using these reinforcing materials are included in the proposed appendix.

University and independent lab structural tests on cob have been conducted and documented since the 1990s. Testing this proposed code has used as the bases of its analysis include: In-Plane Reverse Cyclic Tests as well as small scale batch testing at Santa Clara University; Small Scale batch testing at the University of Plymouth (England); Federal Institute for Materials Research and Testing, Berlin, Germany; The University of Oregon; Wuhan University of Technology, China; the University of San Francisco; and the Washington State University. Shake table test results were also used from the University of Sydney (Australia), and the University of British Columbia (Canada).
This proposed code also drew on the following codes, standards and earthen engineering texts: ASTM E2392 Standard Guide for Design of Earthen Wall Building Systems; the engineered and prescriptive New Zealand Standard for Earth Buildings NZS4297-99; The New Mexico Earthen Building Materials Code; the prescriptive German Earthen Building Standard, DIN 4102; and earthen engineering texts such as Building with Earth: Design and Technology of a Sustainable Architecture, by Gernot Minke.

Gravity load-bearing values are based on project specific, required material tests. Lateral loads are limited to Seismic Design Categories (SDC) A, B, and C, with increased safety factors and decreased Response Modification Factors for SDC C. Gravity and earthquake effects of the cob weight itself have been generated assuming a material density of 110 pcf which is the upper limit of density for all tests assessed. A common density range of 80-105 pcf is expected in the field. Appropriate adjustment factors have been applied for other structural elements and connections contained in other parts of the IRC that may be uniquely affected by the increased dead load of cob walls, such as the roof diaphragm. A full report of the structural analysis that generated this proposed appendix is available at: https://www.cobcode.org/cobcode-documents

COB FLOORS:
Cob floors on grade, with or without straw, are permitted in cob buildings, but the specifications must be approved by the building official. There are numerous viable cob floor systems. The modern evolution and growing use of cob and other earthen floors in high-end custom homes is testament to their serviceability, aesthetic appeal, and low environmental impact.

**FIRE RESISTANCE:**

**ASTM E119 Fire-Resistance Rating Equivalency for Monolithic Adobe (Cob) walls.**

To establish the minimum 1-hour fire resistance rating for a 10” thick cob wall included in this appendix, extensive research was done into existing ratings in codes and standards, testing, and fire experience in earthen wall buildings. A technical equivalency evaluation was conducted by Reax Engineering, Inc., which is summarized below. In addition, it is worth noting that in Australia as in the western U.S., devastating wildfires, or bushfires as they are called in Australia, have been increasing in frequency and intensity. Because of a tradition of buildings with earthen walls in areas that have experienced the most intense bushfires, they have had the opportunity to observe how earthen walls perform in firestorms.

The Australian Standard AS 3959-2009, "Construction of buildings in bushfire-prone areas," was developed as a result. This standard lists "earth wall including mud brick" as one of only three external wall materials not needing additional testing even in the most extreme and vulnerable bushfire zones, BAL FZ (Bushfire Attack Level- Flame Zone). The standard stipulates that the exposed components of external walls shall be of non-combustible material at least 90mm (3.54 inches) thick. Along with earth walls, the other materials listed as acceptable without additional testing for external walls are full masonry and precast or in situ concrete. The minimum 10-inch thick 1-hour cob wall in this proposed appendix is almost three times as thick as the minimum
thickness of the earth wall accepted by that standard for the highest fire risk zones in Australia.

Additionally, the Australian Earth Building Handbook, HB195-2002, in Section 4.6 Fire Resistance Level, states, "In the absence of specific test data, the general fire resistance level (FRL) of earth walls satisfying the minimum thickness requirements outlined in Clause 4.3.4 may be taken as not greater than 120/120/120, or 90/90/90 where wall thickness is less than 200 mm." Clause 4.3.4 Structural Adequacy states: "Minimum recommended thicknesses for mud brick, stabilized pressed block and rammed earth are as follows: External walling - 200 mm, Internal walling - 125 mm. The minimum wall thickness for poured earth and cob wall construction is also recommended to be 200 mm, though in practice wall thickness will often exceed this value."

The three numbers in the FRL represent minutes before failure for structural adequacy/integrity/insulation. In other words the time for the wall to be able to maintain a load, maintain its integrity, and before heat increase on the unheated side of the wall exceeds accepted limits. Thus Australia gives a 2-hour fire resistance rating for a 200 mm (7.87") earth wall. This Standards Australia handbook is available via the supporting documents link above.

Summary of the Reax Engineering Inc. evaluation and analysis of historical tests and other relevant evidence to determine a fire-resistance rating equivalency for cob walls.

Code Requirement

IRC Section R302.1 Exterior Walls and Table R302.1(1) requires 1-hour fire-resistance rated walls to be tested in accordance with ASTM E119 or UL 263 with exposure from both sides. E119 fire-resistance ratings ≥ 1 hour must include a one-minute hose stream test following the fire-resistance test.

Proposed Equivalency

ASTM E119 and equivalent international tests AS 1530 and EN 1363 on closely-related compressed earth block and adobe block walls, were used to demonstrate a minimum of 1-hour fire resistance of Monolithic Adobe (Cob) walls greater than or equal to 10 inches thick, including a significant factor of safety.

Rational Engineering Analysis of Proposed Equivalency

Reax Engineering Inc. evaluated results from standardized testing, published standards, and empirical evidence, to establish a conservative minimum value for the fire resistance of monolithic adobe (sand, straw and unfired clay in monolithic form). Data was from allied construction systems using the same sand, clay, straw materials in brick form (brick and monolithic walls of these materials are referred to collectively as "earthen walls").

The tests are described below and summarized in Table 1. All tests except test (c) (run to insulation failure) passed all parameters tested: loadbearing, integrity, insulation. Test (a) also included and passed a hose stream test. All wall specimen sizes were 10’ x 10’ or the close metric equivalent of 3.1 x 3.1 meters.

Test Descriptions

a. A test of a 10" thick, compressed earth block wall was conducted in 2013 in Texas to the ASTM E119 2-hour load-bearing standard. Results for the test including the hose stream component are proprietary but a video is available at the following link: Urban Earth Fire Resistance Test (video)

b. A test of a 9.84" thick compressed earth block wall was conducted in 2011 in South Africa to a 1-hour
standard using an ISO 834 time/temperature curve identical to the ASTM E119 temperature curve. This test provided the basis for a 2-hour loadbearing fire-resistance rating for 9.84” thick compressed earth block wall.

c. A test of a 5.9” thick Cinva-ram earth block wall was conducted in Australia to insulation failure at 3 hrs 41 minutes, to the AS1530.4 standard. It was reported in the Commonwealth Scientific and Industrial Research Organization’s (CSIRO) Bulletin 5: Earth Wall Construction, 1976. CISRO is an independent Australian federal government agency responsible for scientific research.

d. A test was conducted in Australia in 1982 to the AS1530.4-1975 4-hour standard, which is nearly identical to the ASTM E119 4-hour standard. The test provided a 4-hour loadbearing fire-resistance rating for a 9.8” thick adobe block wall. The test was stopped after 4 hours. Researchers extrapolated a 6 to 7-hour rating had the test continued, with heat rise on the unexposed face the predicted limiting factor.

e. A test of a 5.9” thick walls was conducted at the Laboratory for Structures and Fire Resistance at the University of Aveiro, Portugal, using ISO 834 time-temp curve and the European Standards for testing fire resistance (EN1363-1 and EN 1364-1). One wall tested soil stabilized with cement, and one tested soil stabilized with Kraft fibers.

</table>
Several of these tests are on compressed earth block systems which lack the straw component of cob wall construction. Straw adds resistance to heat transfer thus decreasing the rate of surface temperature rise on the unexposed side. Straw in the wall will not combust due to lack of oxygen, and it will continue to offer its primary role in adobe of limiting crack propagation, a property expected to enhance a cob wall’s resistance to thermally induced structural failure.

As a massive system, a monolithic adobe wall can absorb a significantly greater amount of heat when compared to a standard stuccoed wood-framed wall. For slow growing fires, this translates to less heat on the interior, and prolonged time to flashover with increased protection and time for escape.

Photos were reviewed of surviving earthen walls with completely incinerated wooden floor and roof structures in California and Australian firestorms. These show further evidence of the resistance of earthen wall systems to intense fire conditions.

Monolithic adobe is used to construct fireplaces, ovens, kilns, and forges, a testament to its ability to contain fire. It is favored for these applications over concrete, rock, and red brick, for its lesser tendency to crack or spall.

**Comparison to Tests and Adopted Standards**

The engineering judgment was checked against standards from two jurisdictions with prescribed fire-resistance ratings for earthen walls. The Pima County Approved Standard for Earthen IBC Structures, provides a 2-hour rating for a 10” thick wall. New Zealand’s NZS 4297 Engineering Design of Earth Buildings provides a 2-hour rating for a 5.9” thick wall. Thus an engineering judgment of a 1-hour fire-resistance rating for a 10” thick monolithic adobe wall provides a 100% safety margin compared to these standards and as compared to four of the five described tests. A 1-hour rating provides a 300% safety margin compared with the Australian adobe block test that yielded a 4-hour rating.

**Conclusion**

All relevant evidence strongly supports the judgment that monolithic adobe (cob) walls constructed to a minimum thickness of 10 inches provide a conservative minimum fire-resistance rating of 1-hour.

Fire testing reports, related documents and the equivalency report are available at https://www.cobcode.org/cobcode-documents

**THERMAL PERFORMANCE:**

Cob walls are classified as mass walls in accordance with Section N1102.2.5 because the heat capacity of cob walls is greater than the 6 Btu/ft² x °F threshold defined in that section. The lowest heat capacity of a cob wall is 16 Btu/ft² x °F, for the required minimum wall thickness of 10” and at the lowest practical density of 70 pcf.

Cob’s assigned unit R-value of 0.22 per inch with a density of 110 pcf was determined with an ASTM C1363 thermal resistance test at Intertek Laboratory in Fresno, CA in December 2018. The R-value of the wall assembly is determined by adding the thermal resistance of the air films and any finish or additional insulation.

Adding insulation to the face of cob walls can allow them to be used more readily in cold climates. This is allowed, providing the insulation assembly complies with the requirement in Section AU104.1 for attachment or
support, vapor permeance, and weight limits.

**Bibliography:** The following documents relate to one or more categories in the code proposal as indicated: General (G), Structural (S), Fire (F).

Cost Impact: The code change proposal will not increase or decrease the cost of construction. As a wall system cob can be more costly or less costly than conventional wall systems found in the IRC, depending on many variables. The materials for cob walls or clay soil (often from the site), sand, and straw are relatively inexpensive whereas the cob walls can be more labor intensive. Other elements or systems in the building such as the foundation, roof, electrical, plumbing and mechanical can be very similar to those used in conventional construction and therefore the same cost. As an overview this proposal will not affect the cost of construction.
Appendix U
Physical Security

SECTION AU101
General

AU101.1 Purpose. The purpose of this appendix is to establish minimum standards that incorporate physical security to make dwelling units resistant to unlawful entry.

AU101.2 Scope. The provisions of this appendix shall apply to all new structures and to additions and alterations made to existing buildings.

SECTION AU102
Doors

AU102.1 Doors. All exterior swinging doors of residential dwelling units and attached garages, including doors leading from the garage area into the dwelling unit, shall comply with Sections AU102.1.1 through AU102.1.5 based on the type of door installed.

Exceptions: Vehicular access doors.

AU102.1.1 Wood doors. Exterior wood doors shall be of solid core construction such as high-density particleboard, solid wood, or wood block core with a minimum thickness of 1-3/4 inches (45 mm) at any point. Doors with panel inserts shall be solid wood with the insert being a minimum of 1-inch (25.4 mm) in thickness.

AU102.1.2 Steel doors. Exterior steel doors shall be a minimum thickness of 24 gauge and have reinforcement material at the location of the deadbolt.

AU102.1.3 Fiberglass doors. Fiberglass doors shall have a minimum skin thickness of one-sixteenth inch and have reinforcement material at the location of the deadbolt.

AU102.1.4 Double doors. The inactive leaf of an exterior double door shall be provided with flush bolts having an engagement of not less than 1-inch (25.4 mm) into the head and threshold of the door frame, or by other approved methods.

AU102.1.5 Sliding doors. Exterior sliding doors shall be installed to prevent the removal of the panels and the glazing from the exterior.
SECTION AU103
Door Frames

AU103.1 Door frames. The exterior door frames shall be installed prior to the rough-in inspection. Horizontal blocking shall be placed between studs at the door lock height for three stud spaces of equivalent bracing on each side of the door opening. Door frames shall comply with Sections AU103.1.1 through AU103.1.2 based on the type of door installed.

AU103.1.1 Wood frames. Wood frame doors shall be set in frame openings constructed of double studding or equivalent construction. Door frames, including those with sidelights, shall be reinforced in accordance with ASTM F476 Grade 40.

AU103.1.2 Steel frames. Steel door frames shall be constructed of 18 gauge or heavier steel and reinforced at the hinges and strikes. Doors are to be anchored to the wall in accordance with the manufacturer's instructions.

SECTION AU104
Door Jambs

AU104.1 Door jambs. Door jambs shall comply with one of the following:

1. Door jambs constructed as per ASTM F476.
2. Door stops on wooden jambs for in-swinging doors shall be of one-piece construction.

SECTION AU105
Door Hardware

AU105.1 Door hardware. Exterior door hardware shall comply with Sections AU105.1.1 through AU105.1.5.

AU105.1.1 Hinges. Hinges for exterior swinging doors shall comply with the following:

1. At least two screws, 3 inches (76 mm) in length, penetrating at least 1-inch (25.4 mm) into the wall structure shall be used. Solid wood fillers or shims shall be used to eliminate any space between the wall structure and the door frame behind each hinge.
2. Hinges for out-swinging doors shall be equipped with mechanical interlock to prevent removal of the door from the exterior.

AU105.1.2 Escutcheon plates. All exterior doors shall have escutcheon plates protecting the door's interior side.

AU105.1.3 Locks. Exterior doors shall be provided with a deadbolt with a minimum grade 2 as determined by ANSI/BHMA.

AU105.1.4 Entry vision and glazing. All main or front entry doors to dwelling units shall be arranged so that the occupant has a view of the area immediately outside the door without opening the door. The view may be provided by a door viewer having a field of view of not less than 180 degrees, through windows or through view ports.

AU105.1.5 Side light entry doors. Side light doors units shall have framing of double stud construction or equivalent construction that complies with Sections AU103.1.1 or AU103.1.2. Double stud construction or equivalent construction shall exist between the glazing unit of the side light and the wall structure of the dwelling.

SECTION AU106
Alternate Materials and Methods of Construction
**AU106.1 Alternate materials and methods of construction.** The provisions of this appendix are not intended to prevent the use of any material or method of construction not specifically prescribed by this appendix, provided any such alternate has been approved. Nor is it the intention of this section to exclude any sound method of structural design or analysis not specifically provided for in this appendix. The materials, method of construction and structural design limitations provided for in this appendix shall be used unless otherwise approved. Compliance with ASTM F476 will be deemed to be in compliance with this appendix.

**Reason:** In the summer of 1996, Overland Park, Kansas, experienced a series of home invasions resulting in the sexual assault of several women. For the victims of a home invasion, it's more than a property crime; it scares the victim into thinking that the criminal will return only to commit a more violent or heinous crime. To have an emotional investment in their residence is priceless. As a result of these home invasions, the City's Police Department conducted hundreds of surveys of residents in an effort to develop a solution to the home invasions. The results of the surveys lead the City to develop a building code that makes home more safe and secure. You may ask, why secure the front door? What about installing an alarm? Communities across the country continue to report a growing increase in false alarms. In an effort to provide physical security to the homeowner, there needs to be a more reliable option available.

The longer a criminal spends trying to gain access to a home, the greater the risk of detection. In addition, most home invaders will not attempt to break a window, as that makes noise that neighbors could potentially hear. Rather than face these risks, the invader is more likely to try to kick in an exterior door, where they can easily gain access without being detected.

This code change will provide for minimal provisions to be made to a new home under construction that will give the homeowner safety and peace of mind, while delaying and frustrating the criminal. Since this proposal is not dependent on electrical power, these provisions will always be available to the homeowner and will require no further action after installation. There is no on-going cost to the homeowner and these provisions will not affect the overall aesthetics of the home.

**Cost Impact:** The code change proposal will increase the cost of construction
The cost to secure a single door ranges from $40-$60 for a single door unit and between $140 and $180 for a double sidelite unit.

**Staff Analysis:** A review of the standards proposed for inclusion in the code, ASTM F476 and ANSI/BHMA, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 2, 2019.

Proposal # 4864

APPENDIX U
DECK GUARD DETAILS

SECTION AU101
GENERAL

AU101.1 Deck guards. Figures AU101.1(1) and AU101.1(2) are prescriptive options for deck guard, wood post connections to deck framing.
GUARD POST CONNECTION WITH COMMODITY FASTENERS

NOTES:
1. MIN. 2x8 RIM BOARD OR DECK BEAM
2. MIN. 2x8 DECK JOIST
3. MIN. 4x4 GUARD POST, 36" GUARD HEIGHT MAX
4. 4 - 15d COMMON (3 1/2" x 0.162") NAILS, TYP.
5. FULL HEIGHT BLOCKING
6. 1/2" Ø HOT-DIPPED GALVANIZED BOLTS WITH NUTS AND WASHERS
7. 7 - 15d COMMON (3 1/2" x 0.162") NAILS, TYP.
8. 4x4 BLOCKING FULL DEPTH
9. 5/16" x 4" GALVANIZED LAG SCREW

ELEVATION: HARDWARE LOCATIONS    AXON: RIM WITH POST INSIDE FRAMING    AXON: SIDE WITH POST INSIDE FRAMING

FIGURE AU1
GUARD POST CONNECTIONS WITH COMMODITY FASTENERS

UA101.1(1)
GUARD POST CONNECTION WITH COMMODITY FASTENERS
AU2
GUARD POST CONNECTIONS WITH TENSION DEVICE

**Reason:** The Deck Code Coalition (DCC) proposes a new appendix to offer direction for constructing exterior guards on decks where the code is currently silent.

The members of the DCC recognize that there are many methods for constructing guards, and that the inclusion of a single detail within the body of the code may restrict creativity in the building community. However,
there are many people building, specifying, and reviewing decks that are eager for guidance with the complicated connection that is required for connecting deck guard posts to deck framing. Providing a prescriptive detail in an appendix allows us to provide the guidance of an engineered solution that meets the intent of the code.

**Homeowners need these details.** Empirical evidence shows us that over fifty percent of the decks constructed in the country are built by the homeowners themselves. These details might not be the typical by professional, customized deck builders, but they will be infinitely valuable for the homeowner who has little or no construction knowledge, does not want to pay for design services and will build one deck in his/her lifetime. Without prescriptive details, they will either resort to friends, YouTube or other sources, such as DCA6, for guidance. They say, “just show me how you want it, and I will build it that way”.

**Building officials need these details.** Short of having every deck design tested in a lab or sealed by an engineer, there is not a building official who knows if the guards pass muster. The hip check is not a proper testing method. These details are a minimum engineered design which they can look for if they have no other evidence of code compliance.

**Cost Impact:** The code change proposal will increase the cost of construction
Two figures are offered. One figure offers generic, cheap fastening techniques of nails and bolts into blocking, the other figure uses proprietary fasteners for about $20 per post (around $140 for a 144 square foot deck using 7 guard posts).

On the other hand, a savings of time and money could be anticipated for the conscientious homeowner who might pay a professional designer to prepare his deck drawings.

Any extra cost has to be weighed against the increased safety and potential life savings that will occur across the country over many years.

2018 International Residential Code

Add new text as follows:

Appendix U
3D PRINTED BUILDING CONSTRUCTION

SECTION U101
General

U101 Scope. Buildings and structures fabricated in whole or in part using 3D printed construction techniques shall be designed, constructed and inspected in accordance with the provisions contained in this Appendix and other applicable requirements in this code.

SECTION U102
Definitions

U102.1 Definitions. The following words and terms shall, for the purposes of this appendix, have the meanings shown herein. Refer to Chapter 2 of this code for general definitions.

3D PRINTED BUILDING CONSTRUCTION. A process for fabricating buildings and structures from 3D model data using automated equipment that deposits construction material in a layer upon layer fashion.

ADDITIVE MANUFACTURING MATERIALS. Materials used by the 3D printer to produce the building structure or system components of the building.

PRODUCTION EQUIPMENT. The equipment, including 3D printer, its settings, nozzles and other accessories used in the fabrication process.

FABRICATION PROCESS. Preparation of the job site and construction material, and the deposition, curing, finishing, insertion of components and other methods used to build building elements such as walls, partitions, roof assemblies and structural components, and the means used to connect assemblies together.

SYSTEM COMPONENTS. Devices, equipment and appliances that are installed in the building elements as part of the wiring, plumbing, HVAC and other systems. These include, but are not limited to, electrical outlet boxes, conduit, wiring, piping, tubing, and HVAC ducts, each of which is covered by a product standard or Installation Code Requirement.

SECTION U103
Building Design

U103.1 Design organization. 3D printed buildings and structures shall be designed by an organization certified...
in accordance with UL 3401 by an approved agency and approved by the building official based on this section.

**U103.2 Engineered design.** The plans included in the UL 3401 compliance report shall be used for determining compliance with the engineering design requirements in Section R301.1.3 of this code.

**U103.3 Performance design.** The requirements in Chapters 4 through 9 and Chapter 11 of this code shall be waived where the UL 3401 compliance report demonstrates that the 3D printed construction provides an equivalent level of performance as the prescriptive code requirements.

**U103.4 Other Equipment and Systems.** Where not covered by the UL 3401 compliance report, the following provisions of this code shall be used as a basis for determining compliance for the following equipment and systems:

2. Energy efficiency – Part IV.
3. Mechanical – Part V.
4. Fuel gas – Part VI.
5. Plumbing – Part VII.
6. Electrical – Part VIII.

**U103.5 Ratings** The building or structure ratings in the UL 3401 compliance report, including but not limited to fire-resistance, interior finish, roofing fire classification, insulation material R-value shall be suitable for the installation. The acceptability of material and system ratings not included in the compliance report shall be determined by the building official.

**SECTION U104**

**BUILDING CONSTRUCTION**

**U104.1 Construction.** 3D printed buildings and structures shall be constructed in accordance with this section.

**U104.2 Construction method.** The building construction method, consisting of the manufacturer’s production equipment and fabrication process shall be in accordance with the UL 3401 compliance report. The unique identifier of the construction method used shall match the identifier in the UL 3401 compliance report.

**U104.3 Additive manufacturing materials.** Only the listed additive manufacturing materials identified in the UL 3401 compliance report shall be used to fabricate the building structure or system components. Containers of the additive manufacturing materials shall be labeled.

**U104.4 Depositing of manufacturing materials.** Manufacturing materials shall only be deposited where ambient temperature and environmental conditions at the job site are within limits specified in the UL 3401 compliance report. The maximum number of layers permitted, specified curing time and any surface preparation or finishing shall be performed as specified in the UL 3401 compliance report.

**SECTION U105**

**Special Inspections**

**U105.1 Initial inspection** An initial inspection of the production equipment, including 3D printer, and the fabrication process shall be performed after the production equipment is located onsite and before building fabrication has begun. The inspection shall be conducted by representatives of the organization that evaluated the fabrication process for compliance with UL 3401. The inspection shall verify that the fabrication process, including production equipment, 3D printing parameters and construction materials are in accordance with the UL 3401 compliance report, and proprietary information in the UL 3401 detailed report of findings.

**Exception:** Where approved by the building official, inspections of the production equipment, including 3D
printer, and the fabrication process used in a single housing tract shall be conducted on the first building to be constructed, and on a selected number of subsequent buildings, where the same equipment, equipment operators and fabrication process are used on all buildings. The number of inspections to be performed shall be determined by the building official.

Add new standard(s) as follows:

UL LLC
333 Pfingsten Road
Northbrook IL 60062

**UL 3401 -19: Outline of Investigation for 3D Printed Building Construction**

**Reason:** 3D building construction has moved from a conceptual stage to reality, and projects are being proposed in an increasing number of jurisdictions. Unfortunately the prescriptive design and construction requirements in the IRC are not applicable to 3D printed fabrication techniques, so code officials have to approve this construction based on limited equivalency evaluations that may not take into account variations in material properties introduced by the 3D printing process, or variances in the physical characteristics of the construction materials used. The UL 3401 Outline of Investigation for 3D Printed Building Construction was developed to evaluate critical aspects of this construction process, and level the playing field so that 3D printed building techniques comply with an equivalent level of safety and performance as legacy construction techniques currently in the code.

This proposal introduces an Appendix U, which is not mandatory unless specifically referenced in an adopting ordinance. The Appendix includes definitions, and requirements for 3D printed building design, construction and special inspections, which rely on the design being evaluated in advance by an approved agency for compliance with UL 3401. The resulting compliance report includes the information needed by the contractor and code official to verify compliance with applicable code requirements, and to verify that the 3D printing process and materials used on site are the same as those used during the UL 3401 evaluation and testing. The special inspection requirements are necessary because the portions of the fabrication process such as 3D printer settings, deposition rates and thickness, and curing processes, require special expertise to evaluate, especially when they include proprietary formulations, equipment and settings.

A companion proposal introduces revisions to R301.1.1 that also references UL 3401 and 3D printed building construction. These two proposals will work together, but each also stands on its own.

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

The proposal will not increase the cost of construction because it covers a construction technique that is not currently addressed in the code.

2018 International Zoning Code

SECTION 101
SCOPE AND GENERAL REQUIREMENTS
**2018 International Green Construction Code**

**SECTION 101**

**SCOPE AND GENERAL REQUIREMENTS**

**Reason:** The intent of this proposal is to match the section titles currently found in IFC, IECC (C&R) and IWUIC.

**SECTION 101 SCOPE AND GENERAL REQUIREMENTS**

The BCAC is working from the philosophy that ICC is a family of codes, so administrative requirements should be consistent across books. Most administrative and enforcement matters are the same for any code. Those matters unique for a specific code remain unchanged. This is one of a series of proposals being submitted relating to technical, editorial and organizational changes proposed for the Administrative chapters (Chapter 1) in all of the I-Codes.

While the Administrative Committee will consider each proposal independently, the proposals in this package are a correlated set of companion code change proposals.

This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Plumbing/Mechanical/Gas Code Action Committee (PMG CAC).

BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/codedevelopment-process/building-code-actioncommittee-bcac.

The PMG CAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance the International Codes or portions thereof that were under the purview of the PMG CAC. In 2017-2018, the PMG CAC held one face-to-face meeting and 11 conference call meetings. Numerous interested parties attended the committee meetings and offered their input. Related documentation and reports are posted on the PMGCAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/pmg-code-action-committee-pmgcac/

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction

This is an editorial change that provides consistency between I-codes.

Proposal # 4028

CCC-ADM1-19
Proponent: Michael O’Brian, representing FCAC (fcac@iccsafe.org)

2018 International Fire Code
Revise as follows:

PART 2
ADMINISTRATIVE PROVISIONS
ADMINISTRATION AND ENFORCEMENT

Reason: This change to the title will bring consistency with title of Part 2 for all the codes except Performance Code. Currently the IFC is the only code that is different.

PART 2—ADMINISTRATIVE PROVISIONS

The BCAC is working from the philosophy that ICC is a family of codes, so administrative requirements should be consistent across books. Most administrative and enforcement matters are the same for any code. Those matters unique for a specific code remain unchanged. This is one of a series of proposals being submitted relating to technical, editorial and organizational changes proposed for the Administrative chapters (Chapter 1) in all of the I-Codes.

While the Administrative Committee will consider each proposal independently, the proposals in this package are a correlated set of companion code change proposals.

The following is the template utilized to create this code change proposal. There may be some differences depending on the unique applications of each code—such as “building/fire/code official”.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). The FCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes with regard to fire safety and hazardous materials in new and existing buildings and facilities and the protection of life and property in wildland urban interface areas. In 2018 the Fire-CAC has held 3 open meetings. In addition, there were numerous conference calls, Regional Work Group and Task Group meetings for the current code development cycle, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the FCAC website at: https://www.iccsafe.org/codes-tech-support/cs/fire-code-action-committee-fcac/

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is an editorial change that provides consistency between I-codes.
Proponent: Ed Kulik, representing ICC Building Code Action Committee (bcac@iccsafe.org); Pennie Feehan, representing Plumbing, Mechanical, and Fuel Gas Code Action Committee (pmgcac@iccsafe.org); Michael O’Brien, representing FCAC (fcac@iccsafe.org); David Collins, representing SEHPCAC (sehpcac@iccsafe.org)

The BCAC is working from the philosophy that ICC is a family of codes, so administrative requirements should be consistent across books. Most administrative and enforcement matters are the same for any code. Those matters unique for a specific code remain unchanged. This is one of a series of proposals being submitted relating to technical, editorial and organizational changes proposed for the Administrative chapters (Chapter 1) in all of the I-Codes.

While the Administrative Committee will consider each proposal independently, the proposals in this package are a correlated set of companion code change proposals.

This proposal is submitted by the ICC Building Code Action Committee (BCAC), the ICC Fire Code Action Committee (FCAC), the ICC Sustainable, Energy and High Performance Code Action Committee (SEHPCAC) and the ICC Plumbing/Mechanical/Gas Code Action Committee (PMG CAC)

The BCAC was established by the ICC Board of Directors in July 2011 to pursue opportunities to improve and enhance assigned International Codes or portions thereof. Since 2017 the BCAC has held 6 open meetings. In addition, there were numerous Working Group meetings and conference calls for the current code development cycle, which included members of the committee as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: https://www.iccsafe.org/codes-tech-support/codes/odedevelopment-process/building-code-actioncommittee-bcac.

The FCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes with regard to fire safety and hazardous materials in new and existing buildings and facilities and the protection of life and property in wildland urban interface areas. In 2018 the Fire-CAC has held 3 open meetings. In addition, there were numerous conference calls, Regional Work Group and Task Group meetings for the current code development cycle, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the FCAC website at: https://www.iccsafe.org/codes-tech-support/cs/fire-code-action-committee-fcac/
The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance International Codes with regard to sustainability, energy and high performance as it relates to the built environment included, but not limited to, how these criteria relate to the International Green Construction Code (IGCC) and the International Energy Conservation Code (IECC). In 2018-2019, the SEHPCAC has held five two- or three-day open meetings and numerous workgroup calls, to discuss and debate proposed changes and public comments. Attendees at the meetings and calls included members of the SEHPCAC as well as any interested parties. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx

The PMG CAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance the International Codes or portions thereof that were under the purview of the PMG CAC. In 2017-2018, the PMG CAC held one face-to-face meeting and 11 conference call meetings. Numerous interested parties attended the committee meetings and offered their input. Related documentation and reports are posted on the PMG CAC website at: https://www.iccsafe.org/codes-tech-support/codes/code-development-process/pmg-code-action-committee-pmgcac/

**Cost Impact:** The code change proposal will not increase or decrease the cost of construction. This is an editorial change that provides consistency between I-codes.

Proposal # 4047

Proposal # 4047

CCC-ADM3-19
Reason: The change to the title in the IFC is for coordination with the same section in the IBC, IRC, IPC, IMC, IEBC, IPSDC, IFGC, IPMC, ISPSC. The BCAC is working from the philosophy that ICC is a family of codes, so administrative requirements should be consistent across books. Most administrative and enforcement matters are the same for any code. Those matters unique for a specific code remain unchanged. This is one of a series of proposals being submitted relating to technical, editorial and organizational changes proposed for the Administrative chapters (Chapter 1) in all of the I-Codes.

While the Administrative Committee will consider each proposal independently, the proposals in this package are a correlated set of companion code change proposals."

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). The FCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes with regard to fire safety and hazardous materials in new and existing buildings and facilities and the protection of life and property in wildland urban interface areas. In 2018 the Fire-CAC has held 3 open meetings. In addition, there were numerous conference calls, Regional Work Group and Task Group meetings for the current code development cycle, which included members of the committees as well as any interested parties, to discuss and debate the proposed changes. Related documentation and reports are posted on the FCAC website at: https://www.iccsafe.org/codes-tech-support/cs/fire-code-action-committee-fcac/

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This is an editorial change that provides consistency between l-codes.
Proponent: Gregory Robinson, representing National Council of Structural Engineers Associations (NCSEA) (grobinson@byd.com)

2018 International Building Code

Revise as follows:

1704.2.1 Special inspector qualifications. Prior to the start of the construction, the approved agencies shall provide written documentation to the building official demonstrating the competence and relevant experience or training of the special inspectors who will perform the special inspections and tests during construction. Experience or training shall be considered to be relevant where the documented experience or training is related in complexity to the same type of special inspection or testing activities for projects of similar complexity and material qualities. These qualifications are in addition to qualifications specified in other sections of this code.

The registered design professional in responsible charge and engineers of record involved in the design of the project are permitted to act as the approved agency and their personnel are permitted to act as special inspectors for the work designed by them, provided they qualify as special inspectors.

Reason: Several agencies and special inspectors may be responsible for providing quality assurance on a project. There is a misperception among some engineers that if they provide special inspections for one particular scope of work, that they must provide special inspections for all scopes of work because they would be recognized as "the" approved agency per section 1704.2.1. This proposal clarifies that there can be more than one approved agency on a project.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This is a clarification only. No change in cost of work.
2018 International Building Code

Revise as follows:

1504.8 Surfacing and ballast materials in hurricane-prone regions. For a building located in a hurricane-prone region as defined in Section 202, or on any other building with a mean roof height exceeding that permitted by Table 1504.8 based on the exposure category and basic wind speed at the site, the following materials shall not be used on the roof:

1. Aggregate used as surfacing for roof coverings.
2. Aggregate, gravel or stone used as ballast.

Reason: This section applies to a much broader area than hurricane-prone regions. The current title may cause a RDP to miss that fact.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. It only clarifies the affected areas.
CCC-IBC3-19

IBC®: H106.1.1 (New)

Proponent: Marcelo Hirschler, representing GBH International (gbhint@aol.com)

2018 International Building Code

Revise as follows:

H106.1.1 Internally illuminated signs. Except as provided for in Section 2611, where internally illuminated signs have facings of wood or of approved plastic material complying with the requirements of Section 2606.4, the area of such facing section shall be not more than 120 square feet (11.16 m²) and the wiring for electric lighting shall be entirely enclosed in the sign cabinet with a clearance of not less than 2 inches (51 mm) from the facing material. The dimensional limitation of 120 square feet (11.16 m²) shall not apply to sign facing sections made from flame-resistant-coated fabric (ordinarily known as “flexible sign face plastic”) that weighs less than 20 ounces per square yard (678 g/m²) and that, when tested in accordance with NFPA 701, meets the fire propagation performance requirements of both Test 1 and Test 2 or that, when tested in accordance with an approved test method, exhibits an average burn time of 2 seconds or less and a burning extent of 5.9 inches (150 mm) or less for 10 specimens.

Reason: This is simply editorial. It replaces the words “approved plastic” by the words “a plastic material”. Other apparent changes are caused by the web site.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

Editorial change

Proposal # 169
2018 International Building Code

Revise as follows:

1504.1 Wind resistance of roofs. Roof decks and roof coverings shall be designed for wind loads in accordance with Chapter 16 and Sections 1504.2, 1504.3, 1504.4, and 1504.4.1 through 1504.5.

1504.2 Wind resistance of asphalt shingles. Asphalt shingles shall be tested in accordance with ASTM D7158. Asphalt shingles shall meet the classification requirements of Table 1504.1.1 for the appropriate maximum basic wind speed. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D7158 and the required classification in Table 1504.1.1.

Exception: Asphalt shingles not included in the scope of ASTM D7158 shall be tested and labeled in accordance with ASTM D3161. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D3161 and the required classification in Table 1504.1.1.

<table>

</table>

For SI: 1 foot = 304.8 mm; 1 mph = 0.447 m/s.

a. The standard calculations contained in ASTM D7158 assume Exposure Category B or C and building height of 60 feet or less. Additional calculations are required for conditions outside of these assumptions.

Reason: The current numbering hierarchy in Section 1504 is incorrect. The proposal resets the order to read more consistently.

Cost Impact: The code change proposal will not increase or decrease the cost of construction.

The proposal is strictly editorial.
2018 International Residential Code

Revise as follows:

R502.11.1 Design. Wood trusses shall be designed in accordance with approved engineering practice. The design and manufacture of metal-plate-connected wood trusses shall comply with ANSI/TPI 1. The truss design drawings shall be prepared by a registered design professional where required by the statutes of the jurisdiction in which the project is to be constructed in accordance with Section R106.1.

Reason: It appears that the word "design" was mistakenly omitted from the title, "registered design professional." There is a reference to Section R106.1 which uses the title, "registered design professional." "Design professional" and "registered design professional" are two titles used within the IRC and defined in Section 202, but "registered professional" is not.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. This item should be considered a housekeeping item.
2018 International Residential Code

Revise as follows:

R603.3.2 Minimum stud sizes. Cold-formed steel walls shall be constructed in accordance with Figure R603.3.1(1), R603.3.1(2) or R603.3.1(3), as applicable. Exterior wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(16). Interior load-bearing wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(16) based on an ultimate design wind speed of 115 miles per hour (51 m/s), Exposure Category B, and the building width, stud spacing and ground snow load, as appropriate. Fastening requirements shall be in accordance with Section R603.2.5 and Table R603.3.2(1). Top and bottom tracks shall have the same minimum thickness as the wall studs.

Exterior wall studs shall be permitted to be reduced to the next thinner size, as shown in Tables R603.3.2(2) through R603.3.2(16), but not less than 33 mils (0.84 mm), where both of the following conditions exist:

1. Minimum of 1/2-inch (12.7 mm) gypsum board is installed and fastened on the interior surface in accordance with Section R702.
2. Wood structural sheathing panels of minimum 7/16-inch-thick (11.1 mm) oriented strand board or 15/32-inch-thick (12 mm) plywood are installed and fastened in accordance with Section R603.9.1 and Table R603.3.2(1) on the outside surface.

Interior load-bearing walls shall be permitted to be reduced to the next thinner size, as shown in Tables R603.3.2(2) through R603.3.2(16), but not less than 33 mils (0.84 mm), where not less than 1/2-inch (12.7 mm) gypsum board is installed and fastened in accordance with Section R702 on both sides of the wall. The tabulated stud thickness for load-bearing walls shall be used where the attic load is 10 pounds per square foot (480 Pa) or less. A limited attic storage load of 20 pounds per square foot (960 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(2) through R603.3.2(16).

For two-story buildings, the tabulated stud thickness for walls supporting one floor, roof and ceiling shall be used where the second-floor live load is 30 pounds per square foot (1440 Pa). Second-floor live loads of 40 psf (1920 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(2) through R603.3.2(11).

For three-story buildings, the tabulated stud thickness for walls supporting one or two floors, roof and ceiling shall be used where the third-floor live load is 30 pounds per square foot (1440 Pa). Third-floor live loads of 40 pounds per square foot (1920 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(12) through R603.3.2(16).

Reason: The IRC does not recognize nor define the term 'snow load'. The information which is available to the user is that of 'Ground Snow Load'. This is provided through the information contained in Table R301.2(1) which is completed by the local jurisdiction, or through the use of Figure R301.2(6) labeled 'Ground Snow Loads'. The equations involved in the adjustment of 'ground snow load' to a usable design 'snow load' are found in ACSE7 and are used to develop the tables in the IRC, but are not, however, found in the IRC nor are they available to the general user of this code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The modified language is only intended to clarify the use of a term.

Reason: The IRC does not recognize nor define the term 'snow load'. The information which is available to the user is that of 'Ground Snow Load'. This is provided through the information contained in Table R301.2(1) which is completed by the local jurisdiction, or through the use of Figure R301.2(6) labeled 'Ground Snow Loads'. The equations involved in the adjustment of 'ground snow load' to a usable design 'snow load' are found in ACSE7 and are used to develop the tables in the IRC, but are not, however, found in the IRC nor are they available to the general user of this code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction

The modified language is only intended to clarify the use of a term.
CCC-IRC10-19
IRC®: R802.10.2

Proponent: Steve Mickley, American Institute of Building Design, representing American Institute of Building Design (steve.mickley@aibd.org)

2018 International Residential Code
Revise as follows:

R802.10.2 Design. Wood trusses shall be designed in accordance with accepted engineering practice. The design and manufacture of metal-plate-connected wood trusses shall comply with ANSI/TPI 1. The truss design drawings shall be prepared by a registered design professional where required by the statutes of the jurisdiction in which the project is to be constructed in accordance with Section R106.1.

Reason: It appears that the word “design” was mistakenly omitted from the title, “registered design professional.” There is a reference to Section R106.1 which uses the title, “registered design professional.” “Design professional” and “registered design professional” are two titles used within the IRC and defined in Section 202, but “registered professional” is not.

Cost Impact: The code change proposal will not increase or decrease the cost of construction
This item should be considered housekeeping.

Proposal #5217
2018 International Residential Code

Revise as follows:

R602.3.1 Stud size, height and spacing. The size, height and spacing of studs shall be in accordance with Table R602.3(5).

Exceptions:

1. Utility grade studs shall not be spaced more than 16 inches (406 mm) on center, shall not support more than a roof and ceiling, and shall not exceed 8 feet (2438 mm) in height for exterior walls and load-bearing walls or 10 feet (3048 mm) for interior nonload-bearing walls.

2. Where ground snow loads are less than or equal to 25 pounds per square foot (1.2 kPa), and the ultimate design wind speed is less than or equal to 130 mph (58.1 m/s), 2-inch by 6-inch (38 mm by 140 mm) studs supporting a roof load with not more than 6 feet (1829 mm) of tributary length shall have a maximum height of 18 feet (5486 mm) where spaced at 16 inches (406 mm) on center, or 20 feet (6096 mm) where spaced at 12 inches (305 mm) on center. Studs shall be No. 2 grade lumber or better.

3. Exterior load-bearing studs not exceeding 12 feet (3658 mm) in height provided in accordance with Table R602.3(6). The minimum number of full-height studs adjacent to openings shall be in accordance with Section R602.7.5. The building shall be located in Exposure B, the roof live load shall not exceed 20 psf (0.96 kPa), and the ground snow load shall not exceed 30 psf (1.4 kPa). Studs and plates shall be No. 2 grade lumber or better.

Reason: The IRC does not recognize nor define the term 'snow load'. The value which is available to the user is that of 'Ground Snow Load'. This is provided through the information contained in Table R301.2(1) which is completed by the local jurisdiction, or through the use of Figure R301.2(6) labeled 'Ground Snow Loads'. The equations involved in the adjustment of 'ground snow load' to a usable design 'snow load' are found in ACSE7 and are used to develop the tables in the IRC, but are not, however, found in the IRC nor are they available to the general user of this code.

Cost Impact: The code change proposal will not increase or decrease the cost of construction. The modified language is only intended to clarify the use of a term.
